It cannot be surprising, then, that the English potters were very anxious to produce such a body, and if that object could be obtained, the means by which it was attained were secondary matters, and we find that instead of continuing the manufacture of hard paste porcelain, they produced, about the end of the 18th century, (1) a beautiful white earthenware which for generations secured the market of the world, and made it possible to replace almost all other pottery for domestic purposes. (2) A translucent white porcelain similar to the Chinese, by the use of other materials and methods, equally beautiful, which for over a century has held its own amongst all other porcelain productions, and which is generally known as Bone China.

The ceramic productions of the world as regards their bodies or paste, apart altogether from decorative effects, vary from goods made from the coarsest to the finest clays, through almost every variety of texture by admixture of the natural clay with other materials, such as sand, flint, barytes, feldspathic rock, etc. From these materials were produced at one end of the scale the cinerary urns of our great ancestors, and at the other end, the excellent hard paste porcelain which we are considering to-day.

The marvellous difference in the productions of the various peoples of the world may probably be explained by the general assertion that the potters

have from the very earliest times worked with the materials they had at hand. The cinerary urns of the Ancient Britons were made from natural clays.

The Staffordshire potters used, at first, natural clays, found cropping up simultaneously with the coal, and subsequently improved the colour and texture of the product by the addition of, first, fire clay, then Devon and Cornish clay, and calcined flint. Messrs. Eler Bros. used the red marl of the Burslem district for their fine red ware. Bottcher of Germany at first made red ware from local clays, etc., and afterwards porcelain from the white clays or kaolin, and pegmatite.

The Chinese for centuries had been working with their natural materials, kaolin and petuntze, and from these produced their fine porcelain. Some of these various clays naturally required a much greater heat than others to produce hard vitreous bodies.

These varying conditions with regard to materials to the hand of the potter, when means of communication were so restricted, necessarily involved very varied methods of manufacture. The materials differing so essentially from each other naturally required very varying degrees of heat necessary to bring to maturity.

The kaolin and petuntze used by the Chinese would require a much higher temperature to mature than the clays, etc., used in other countries at the time. The exact temperature would not be found at once, and in working out the same an observant potter could not fail to notice the changes taking place in the fired material in regard to vitrification, translucency, and finally distortion at the various temperatures. Thus in all probability without any more scientific knowledge whatever than careful observation, the fine product of that time would be produced which even now (centuries later) is the object of our research.

While the Chinese were for centuries making the most suitable material in the world for chemical laboratory ware, they had no use for such, and consequently did not make it. It was only with the advance of scientific chemical knowledge in Europe, that the need was felt for the various porcelain accessories that were then called into use.

It is not surprising, therefore, that Germany and France having continued making the Chinese type of porcelain, should have applied themselves to this particular demand, and while the English porcelain manufacturers were busy on their own particular class of porcelains they should have almost entirely secured the trade of the world in this branch.

With the cessation of the importation of Continental porcelain into this country, came the call to the English potter, and, as might have been expected, it was not every manufacturer that would listen to the call, neither was it needful that they should.

There was no very tempting offer of any lucrative opening in the new business, and a potter must be more tempted by patriotism to his country, and a desire to meet its needs, than by immediate prospective financial success.

Definition of porcelain.

It is almost impossible to give a definition of chemical porcelain which could generally be regarded as entirely satisfactory. When first porcelain was introduced into Europe, its translucency was sufficient to differentiate it from all other ceramic productions of that period.

We have seen in the attempts to produce a similar porcelain in Great Britain and the Continent other kinds of translucent pottery were discovered, which are known under other names, such as bone china, soft paste porcelain, etc., the former of

which for over a century has held its own amongst the finest productions of the world.

It is quite clear then, that what was once the predominant and characteristic definition of Chinese and Continental hard paste porcelain is so no longer, and translucency alone could never be regarded as the guarantee of chemical porcelain. Translucency is only one of the properties of porcelain and that rather of beauty than utility, as evidenced by the fact that so much of the beautiful translucent porcelain of England has been found useless for the purposes we have in our minds at the moment. To understand the nature of the porcelain required for this purpose needs a clear conception of the uses to which it is to be applied and consequently the qualities required of it.

Properties of porcelain.

In order to decide on the possibilities of the manufacture and the manner of procedure, it was desirable to consider the relative importance of the qualities demanded.

These vary very considerably in their degree of importance, and I am inclined to place them in the following order.

1st. The first and foremost quality, I submit, is that of *resistance to very sudden changes of temperature* of as wide a range of heat as possible without cracking during the operation or at its close on cooling. The greater the range of difference in the temperature the porcelain will allow itself to be subjected to in the quickest time without cracking or breaking, the better and more suitable the porcelain.

2nd. *The resistance of the glaze to the action of chemical reagents* so that the solution may not take up additional weight by dissolving portions of the glaze and thus leading to false estimations in chemical analysis.

3rd. *The colour of the porcelain* should be white or cream, although for special purposes green, blue, or black is sometimes used.

4th. *Fusing point.* The glaze should resist fusion at temperatures well above that at which the articles are generally used.

5th. *The weight of the material.* This is not a very important matter, but it is inadvisable to put excessive weights upon delicate balances, and secondly, liability to cracking increases considerably with the thickness of the material.

6th. *Composition.* The materials which enter into the composition of a porcelain for chemical laboratory purposes appears to matter very little, providing the qualities required for the purpose are complied with; e.g., we are all quite well aware of the fact that one of the materials entering into all porcelains, namely, silica, can without any other additions be made by fusion to fulfil perfectly all the conditions required, unless the material being tested reacts with the silica itself at the temperature.

7th. *Translucency.* This appears to be a quality which is not absolutely necessary for the purpose and may be dispensed with entirely without detriment to the article, provided the other qualities are correct. A piece of very translucent pottery may, for the purposes we are considering, be much worse than a piece of very feeble translucency.

The question now becomes, is it necessary or compulsory to confine ourselves to the methods of either the Chinese or Continental manufacturers? Are these the only ones open to us?

We have seen that it was possible to use materials in such proportions that the firing temperature became a necessity on account of the proportions of fusible to infusible materials present, which needed the high temperature in order to give to it one of its qualities which is not a necessity.

Hence with similar or other materials, it was quite feasible to suppose that the same end could be attained by regulating the length of time the glaze is allowed to remain in a fusing condition on the ware.

Materials.

The materials generally used in hard paste porcelain bodies are ball clay, china clay or kaolin, quartz or flint, felspar, Cornish stone, pegmatite, sometimes a very small proportion of lime, and sometimes ground broken porcelain.

Manufacture.

The materials are weighed out in their proportions, and by the usual blunging operations are intimately mixed by using a large excess of water. The mixture is passed over sieves to abstract any coarsely ground materials, and passed through a trough containing magnets to eliminate any particles of iron either present in the clay as pyrites or other magnetic forms, also from the wearing of the bearings of the machinery. It is then passed through the filter presses from which, when the excess of water has been removed, it is taken as oblong sheets of plastic clay approximately 6 ft. long \times 2 ft. wide \times $\frac{3}{4}$ in. thick. These sheets are then rolled up for convenience of removal and passed through a pug mill where the clay is made homogeneous, the air driven out, and extruded as a continuous mass of plastic clay of a square section about 6 in. and cut off in convenient lengths. It is now ready for use for most purposes, but sometimes is still further improved by wedging or by rolling on machines by the French method.

Castings.

This consists of pouring the slip or body mixture into moulds made of plaster of Paris, and allowing it to remain there for a definite period, when the surplus is emptied out and the article is dried and removed from the mould. The thickness depends upon the length of time the slip is left in the mould. There is always a liability to get differences in weight and thickness which may account for cracking for the following reasons.

First.—The articles may be made so thin that although they are on that account able to conduct or disperse the heat quickly when suddenly heated or cooled there is not sufficient mechanical strength to withstand the strain.

Second.—In making the article thick enough to withstand the mechanical strain, there is a great danger of making it so thick that the porcelain is cracked owing to unequal expansion or contraction.

When the articles are made they are placed in fire-clay receptacles called saggars, which are arranged one upon another in the ovens for firing. The matter of placing is of very great importance and requires great experience and care. When the oven is filled it is either fired according to the method adopted by the hard paste manufacturer whose work we are considering, or by the English method.

The Chinese and Continental manufacturers invariably give their clay ware an easy or low temperature treatment in the first firing, which not only facilitates the subsequent dipping process, but also gives the glaze when fusing upon the surface of the biscuit during the second fire, a better chance of assimilating itself to the body. This can be clearly seen by the absence of a sharp dividing line between the glaze and the body, which is often seen in earthenware and china. The English manufacturer, on the contrary, invariably gives the highest degree of temperature during the first fire.

In some instances where the article is sufficiently strong to be dipped into the glaze without collapsing

and losing its form, it is fired both for body and glaze at the first and only fire, but this procedure is rather restricted in its extent by the nature of the articles, and generally it is preferable to submit the goods to the easy fire first, *e.g.*, it would not be found an easy process to dip evaporating basins in the clay state without collapsing. The first firing, except in the case last mentioned, viz., the clay dipped goods, produces what is known as the biscuit or once-fired goods, the surface of which is rough and without glaze.

This ware is then emptied from the saggars, carefully inspected, faulty goods eliminated, brushed to remove any particles of sand, and passed on to be dipped, which means the glazing process, which consists of dipping the articles in a mixture of compound silicates of alumina, potash, calcium, etc., etc., ground to a fine powder and held in suspension in water, or in ground felspar and lime as practised by the Chinese.

The glaze when dry is then removed from such parts as needful to prevent the pieces sticking to each other during the fusion of the glaze in the next or second firing operation. Another method of separation is by the use of stilts and spurs of various designs. To keep the goods true in form in the second firing is one of the most difficult problems of the manufacturer of chemical porcelain.

The firing of the oven is usually taken to a higher temperature than that of the first or biscuit firing, and takes about 50/60 hours or more to complete.

The judgment of the temperature reached during the operation is effected by various pyrometers, including electrical pyrometers, radiator pyrometers, Wedgwood pyrometers, pyro cones, recorders, etc., etc.

When fired there is still another operation, namely, that of removing any stray bits of sand, sagger dirt, etc., etc., adhering to the glaze, which is accomplished very much on the principle of the glass cutters' operation, who no doubt introduced it to the potters' industry.

The last and final operation is selection and packing.

Testing.

The method of testing the suitability of a porcelain for chemical purposes does not appear to be standardised. Samples sent to one analyst may be treated in quite a different manner to those sent to another.

The three essential qualities that need to be tested for are as follows:—

(1) The resistance to sudden changes of temperature without cracking.

(2) The resistance of the glaze to the action of chemical reagents.

(3) The fusing point of the glaze.

The first of these (the resistance to sudden changes of temperature without cracking) appears to be the most important, judged from the number of tests applied to this particular quality by the German chemists.

Out of 9 tests applied to the Haldenwanger porcelain, 7 were those applied to this quality, while 2 only were applied to the resistance of the glaze to the action of chemical reagents.

German. Seven methods of testing.

(1) Heated repeatedly for 2 days on a Bunsen burner and allowed to cool.

(2) Exposed to great heat and then suddenly placed on a cold metal plate.

(3) Immersed in water for 6 days and then heated until glowing.

(4) Made red hot on a burning gas flame and suddenly placed on a cold metal plate.

(5) Made red hot, gas turned off, and immediately exposed to a blast of cold air.

(6) Heated up to melting point to Seger cone 610-950° C. in a muffle furnace, sustained at that for 10 mins., then quickly taken out and placed on a cold stone.

(7) Same experiment as last, taken up to melting point to Seger cone 1-1150° C.

English. Four methods of testing.

(1) Crucible filled with wax and heated until the temperature rose to 130° C., then allowed to cool to 125°, to insure that the outer layers of the porcelain did not exceed this temperature.

(2) Crucible plunged into cold water at 15° C., and the same experiment repeated at 175°, 200°, 225°, and 250° C.

(3) Crucible placed in a muffle heated to about 900° C. and when thoroughly heated, removed and allowed to cool in the air.

(4) Crucible plunged into a furnace at dull red heat, approx. 550° C., and allowed to cool in the air.

The resistance of glaze to the action of chemical reagents.

The action of water on the vessels is determined in the manner usually employed for glass ware, viz.:—Very carefully prepared distilled water is placed in the vessels, which are then heated to 80° C. for 3 hours. The action of the water is determined with iodococin, equal volumes of water being used for each dish, and the same volumes equally distributed between 3 crucibles. The contents after treatment with iodococin are placed in the series of comparison cylinders to observe the difference in alkalinity. The volume of iodococin solution required to restore the colour determines the amount of acid or alkali dissolved from the porcelain.

A second test is made as before but the action is continued for 6 hours at 100° C.

Action of alkali.

The dishes are heated in a steam oven, cooled in a desiccator and weighed. Fifty cubic centimetres of caustic soda solution (40 grms. per litre) is placed into each of the dishes, and another 16 c.c. divided equally between the 3 crucibles. After heating in a perfectly closed oven so that no liquid is evaporated, for 3 hours at 80°, the dishes are removed and cleaned, then heated in a steam oven, cooled in a desiccator and weighed, the difference in weight giving the amount of silica or other materials dissolved.

The same method as the foregoing is adopted but with caustic potash for 5 hours at 100° C. instead of 3 hours at 80°.

Action of sulphuric acid.

In this test 5 c.c. of normal sulphuric acid (49 grms. per litre) is placed in each crucible, and carefully evaporated, finally volatilising the sulphuric acid by heating over a Bunsen burner. The crucible is then weighed and any difference in the weight gives the amount of loss sustained by the crucible.

Action of nitric acid.

The action of nitric acid on the crucibles is tested for 5 hours at 100° C.

Recent output.

More than 150 years' experience of the manufacture of hard paste porcelain at the State supported Royal Factory of Berlin, the experience of which was placed at the disposal of the porcelain trade of Germany, gave it a tremendous advantage over the English manufacturer. It was therefore no light task for an English manufacturer, minus

that experience, under entirely different conditions, with all the models and moulds to prepare, to attempt the task. Some three or four English manufacturers, however, have attempted the same with very considerable success.

While I cannot speak with any degree of confidence in relation to the manufacture or supply of other factories than our own, I think I may safely say that there is now no very serious occasion to go abroad for any of the chemical porcelain accessories needed in this country.

In spite of all the difficulties surrounding the problem, English samples were in the hands of the dealers for testing purposes in November, 1914. On and by the 20th January, 1915, deliveries were commenced. The permanent success of the venture for all the firms concerned will depend upon the behaviour in use.

Doubtless demands will be made upon our manufacturers, from time to time, for very special articles, such as the condensing worms as shown in the Royal Berlin Catalogue, page 107, but if our Government will behave towards her potters as Continental countries have done to theirs, such articles will be made by special assistance.

We cannot refrain from expressing a sense of satisfaction that something has already been done by making a grant of £10,000 to the North Staffs. Technical School, Stoke-on-Trent, for experimental work in connection with hard paste porcelain, and extensive scientific research work in that direction is being carried out under the superintendence of Dr. Mellor.

Future prospects.

With regard to the future of the trade, it may be well to repeat, that the English potters for two years now have supplied Great Britain with nearly all that has been needed for scientific work, as also for chemical processes in connection with the war. The cry, therefore, that it cannot be done, is no longer admissible.

We may not at present have succeeded in making anything superior to the German production, but I venture to say that in much less time than chemical hard paste porcelain has been manufactured, our country will be making something superior.

Much will depend on conditions prevailing after the war as to the permanent success of the undertaking. That there will be a keen fight for the trade goes without saying.

The Germans will not very willingly relinquish their hold upon a trade they have held so long. Other countries also will compete. France, Denmark, Japan, and Russia have already commenced to supply and the "Engineer" says:—"Like this country, America, prior to the war, depended upon Germany for porcelain articles used in chemical work, and especially for laboratory work. Since the war the German supply has ceased and much inconvenience was caused to chemists across the Atlantic. To-day, however, we learn that American pottery manufacturers are producing porcelain equal to any produced in Germany."

The aim of the English potter in relation to this matter should be not slavishly to copy the hard paste porcelain, but rather to follow the method pursued in the past, viz., to produce his own particular type of porcelain; but in this case it should be a porcelain suited to the particular requirements. The occasion is ripe for the introduction of something better than anything yet produced, and whatever the slight difference as to the colour and the degree of translucency, the main endeavour should be to produce a porcelain that will fulfil the requirements demanded of it. At present unfortunately there are no definite requirements laid down, and this association could render the potters very valuable service in

arranging in some definite form the tests that should be laid down, *e.g.*, what temperature should the porcelain be expected to stand without cracking, and at what speed should the heat be applied? To what degree of temperature may the glaze be expected to be raised without softening? What limitations should be made to the chemical operations that should be allowed in porcelain crucibles? Unfortunately students are instructed how to use a platinum crucible, but seldom so with a porcelain crucible. Of course the porcelain crucible to be sold for a few pence ought to be expected to stand all sorts of usage. Unfortunately that previously in use will not do this.

Inquiries show that there has always been a considerable percentage of loss on the Continental porcelain, and from tests made by the writer on a number of Continental crucibles and evaporating dishes, the following data has been supplied:—

The Continental porcelain varies in quality amongst the various makers and even from the same maker; of two crucibles tested immediately one after another, under exactly the same conditions, one cracked whilst the other remained perfect. On increasing the severity of the test, every piece of five different Continental porcelains broke down under conditions which might very readily obtain in any chemical laboratory.

DISCUSSION.

Professor T. TURNER said that if the crucibles now being produced were not so good as German crucibles, they were of a reasonably good quality and sold at a reasonable price. They hoped that the present success would not be limited to the time of restricted competition, but that the trade would increase in volume when peace came.

Mr. R. H. PICKARD said he thought Mr. Watkin would be well advised to pay special attention to the action of alkalis on chemical porcelain. It should be recognised that there were two kinds of such porcelain in use—one a cheap kind for students; the other, of a higher quality, for important analytical work, which would resist the action of chemical reagents.

Mr. G. N. HUNTLY pointed out that chemical porcelain was used for a variety of purposes; small articles such as crucibles had to resist sudden changes of temperature, to which dishes used for evaporation, etc., were not subjected; in the latter case the essential property to be secured was effective resistance to reagents.

Mr. WATKIN, in replying on the discussion, said there was no doubt that in many respects silica would be better than porcelain. As to alkalis acting upon the English products and in some cases penetrating the glaze, he pointed out that no tests were really satisfactory unless they were comparative. Though some pieces of English chemical porcelain had been rejected as defective, he felt sure that many German samples, if subjected to the same tests, would also have failed.

SANDS USED IN METALLURGICAL PRACTICE WITH COMPARATIVE NOTES ON THOSE USED IN GLASS-MANUFACTURE.

BY PROF. P. G. H. BOSWELL, D.SC., A.R.C.SC., D.I.C., F.G.S.

Prefatory.

The increase in the output of glass of all kinds and the augmented production of metals and alloys—particularly of the ferrous group—resulting from the demands for munitions of war, has necessitated the investigation and utilisation of British resources of sands to a much greater extent than heretofore. Moreover, before the

outbreak of war, unnecessarily large supplies of foreign sands were imported into this country, particularly for lining the hearths of furnaces, for steel-castings, and for the making of the best qualities of glass. The reduction of the available labour and shipping compelled steel-founders and glass-manufacturers to look to home supplies, and the geologist was naturally called upon to assist in satisfying the urgent national needs. Except in the case of one or two foreign supplies of sand, which so far as investigation has gone up to the present have not yet been equalled in the British Isles, it has always been clear that the country could be self-supporting in this connection. When peace conditions once more reign, economic considerations will be the determining factor which will say whether we shall use our native supplies, or unnecessarily jeopardize the safety of a key-industry by still being dependent upon sea-borne material.

It is appropriate that these questions should be raised at a meeting in a city which has long been notable for its sand deposits. If ever there was "matter in the right place," it is the excellent red moulding-sand for which the Birmingham district is famous and from which it has been sent, incredible as it may seem, to many distant parts of the world.

In this paper the requirements of the glass-industry, so far as sands are concerned, can be no more than mentioned incidentally. British resources of glass-sands have been already treated in practically exhaustive detail by the writer.*

The same sand is often very valuable for both glass-making and refractory work. In metallurgical practice the sands required may be classified into those used (A) in moulding, (B) in lining hearths and furnace-bottoms, and (C) in silica brickmaking. Moulding-sands may be subdivided into those used (i) with a natural bond, and (ii) with an artificial one. Sands used in good glass-making are in most cases precisely the same as those used in classes A(ii), B, and in part C, above. The resources may in this respect be treated together.

We are not yet in a position to discuss refractory sands exhaustively; the requirements differ according to the kind of metal made, the ores used, the type of furnaces, and the craft and prejudices of the user.

If ever there was a case made out for the accumulation of a large number of facts, it is in the matter of refractory materials. The generalisations will follow later; at present the work must run on two lines: (A) Analyses must be made of successful and likely supplies; (B) We must have the carefully recorded results of their trial in the works on a commercial scale. In the latter direction, as in many others, where it is knowledge we are seeking, the next best thing to success is failure.

Information which analyses may supply.

This Society is one which concerns itself more particularly with chemical questions, but it is manifestly impossible, in the case of natural deposits used in such industries as glass-manufacture and metal-production, to divorce the considerations of chemical composition from those of texture, constituent minerals, etc. We need therefore three types of analyses of sediments like sands, clays, and crushed rock-materials used in commerce: chemical, mechanical, and mineralogical. For example, the value of a natural moulding-sand depends upon the texture, that is, the mechanical composition, as well as the chemical constitution. Probably, it is the chemical composition of each

* "British Resources of Sands Suitable for Glass-Making, with Notes on Certain Crushed Rocks and Refractory Materials"; published at the instruction of the Ministry of Munitions of War; Longmans, Green & Co., London, 18. 6d.

And Supplementary Memoir in course of publication.

separate "grade" (see below) which counts. Again, the fritting of high silica sands used for glass-making, furnace-lining, etc., depends on the grade-size and angularity of the sand, as well as upon the silica-content. It is axiomatic to say that fine-grained sands melt more readily than coarse ones.

Actual figures being accessible elsewhere, it appears undesirable to load with them a paper which, from its title, must necessarily be general where the field is so vast. They are therefore only used illustratively. Notes on new methods of work, precautions to be observed, indications of directions where further information is required, and a general statement as to how far the country can be self-supporting, will be of most value.

Chemical analyses of sands.

Chemical analysis should be carried out in the usual manner, but by a chemist familiar with the methods and precautions to be adopted in making analyses of silicate rocks.* Care should be taken by repeated precipitation that too high a result is not obtained for the silica. It is not sufficient to estimate it by difference. Alumina should be estimated (as Al_2O_3). In the case of glass-sands alumina is frequently of value for special glasses (certain optical glasses, thermometer and resistant glasses, etc.) or for its toughening and strengthening properties (bottle-glass). In high-silica sands for refractory purposes it tends to cause fritting at a lower temperature; its presence in small quantity is thus desirable in sands used for furnace-hearthths.

The total iron may, for glass-making purposes, be recorded as Fe_2O_3 , and since in the case of good glass-sands there is a very low percentage (0.02 or less, to 0.06), it is estimated on large and separate samples by colorimetric methods. Many excellent high-silica sands contain up to 0.2% of iron oxide, an amount too great for the making of better-class glass, but quite low enough for the highest refractory demands. Most of the laboratory determinations of iron, like those of silica, appear to be too high. In any case, iron oxide should not rise over 3% and if the sands are to be used under reducing conditions, it should be much less, or the result will be the production of the easily fusible ferrous silicate from combination with some of the quartz present.

In glass-sands which contain more than 0.5% of alumina, it is desirable to look for and estimate titanium. In the form of the mineral rutile (TiO_2) or, less commonly, its isomers anatase and brookite, it is frequently plentiful in sands and quartzose rocks. Exactly what rôle it plays we do not know, but it is clear that in quantity it is decidedly inimical in glass-making. The precise part played by small quantities of so-called impurities in sands, whether in glass-manufacture or in industries using refractory materials, is not yet known, and indicates the need for experimental work and exact analyses. These "impurities" may behave as catalytic agents in facilitating conversions. It is a remarkable fact that titanium is always high in fireclays, most of which are exceedingly refractory, whether they are found in this country, on the Continent, or in America.† A search does not yield rutile or its isomers, and we are therefore led to think that the substance is scattered throughout the clay, possibly in a colloidal or clay-like form.

For glass-sands, other impurities such as lime, magnesia, alkalis, etc., are best absent, or if present should be as "a trace" only. When

required they may be added quantitatively to the "batch," or mixture of raw materials. The alkalis and alkaline earths form, of course, essential constituents of glass, so that their presence in a glass-sand is not inimical. The very reason which requires their presence to make a glass, renders them forbidden constituents in any sand which is to be of value for resisting high temperatures. It is a well-known phenomenon that a particular mixture of substances mutually soluble in one another has a lower melting point (the "eutectic" point) than that of any of the individual substances, and for each pair, triplet, or quadruplet, etc., of substances a definite percentage mixture (the "eutectic composition") always possesses the lowest melting-point. As a common example from everyday life, we may quote that of a mixture of salt and ice. The freezing-point of the mixture in the most suitable proportions for the attainment of low temperatures (23.8 of salt to 76.2 of water) is $-22^\circ C$. Such well-known alloys as those of copper and silver, of the various steels, and even solder itself, provide similar instances. Solder is used on account of the readiness with which it melts. Timman's solder consists of about 60% of lead (melting point $327^\circ C$) and 40% of tin (melting point $232^\circ C$), and possesses a melting point itself of about $180^\circ C$. The mineral constitution and texture of rocks which have been formed by cooling from the molten state are found to be controlled to a large extent by these considerations of eutectics. The compounds and minerals occurring in rocks are those which are also constituents of glass and refractory materials. The rock known as obsidian has the appearance, properties, and composition of a common "black" bottle-glass. Most refractory materials are natural rock-substances. Silica has a melting point about $1600^\circ C$, alumina (for example, as the artificial refractory material, alundum) about $2020^\circ C$, magnesia about $2000^\circ C$, and lime about $1990^\circ C$. Each of these is highly refractory. Aluminium silicate ($Al_2O_3 \cdot SiO_2$), however, as the mineral sillimanite (which is the isomeric form with the highest melting point), crystallises at $1300^\circ C$. Calcium silicate ($CaO \cdot SiO_2$) as the mineral wollastonite, or rather pseudo-wollastonite, to which it inverts, melts at $1512^\circ C$. Numerous other examples might be adduced, but in illustration of the principle, there may be quoted in conclusion only the "Seger" and other types of cones used for temperature determination in furnaces. The cones are mixtures of these substances and the alkalis, and possess a range of melting points according to the composition of the mixture of which they are made.

The addition of potash and soda, or even of lime to a sand therefore, so far reduces the melting-point of the mixture as to enable a glass to be formed. More refractory glasses which are required to possess a higher melting-point and to withstand subsequently a greater heat without softening or devitrifying, are produced by the use of alumina, magnesia, boron, etc. For example, the Thuringian sand used so successfully for thermometer-glass contained 3.66% of Al_2O_3 , the remainder being silica.

It is clear, on the other hand, that sands to be used for refractory purposes should be as highly silicious as possible, or failing that, should contain silica and alumina only. Most sands are quartzose, that is, are wholly or almost wholly composed of quartz (SiO_2). As examples of the best of these, we may quote:—

The next most commonly occurring mineral in sands is felspar. The felspar group of minerals con-

analysis. For glass-making purposes, inimical elements, such as iron, titanium, and zirconium, can be determined at once.

The following table includes analyses of sands which have proved very suitable for lining Siemens furnace-hearths, for the beds of reheating furnaces, etc.

	SiO ₂ .	Al ₂ O ₃ .	Fe ₂ O ₃ .	CaO.	MgO.	Alkalis.	Loss on ign.	Total.

alumina. The presence of the alkalis, even in small quantity, has the effect which would be expected, namely, that of lowering the refractoriness. Muscovite mica is a related hydrous compound of potash and alumina and has a similar effect. Generally speaking, therefore, felspathic and micaceous sands and rocks must be avoided in refractory work. Felspar, however, is not a stable mineral: it decomposes to micas and then to clayey aggregates (china-clay) by the leaching out of its alkalis as a result of the atmospheric agencies or chemically active gases and solutions. In this way are produced the refractory china-clay of Devon and Cornwall, and the highly aluminous, but lime- and alkali-free sands of Derbyshire, so valuable for the manufacture of silica-bricks. For such purposes as fettling Siemens furnace-hearths, lining reheating-furnaces, etc., it is not desirable to use the exceedingly refractory quartzose sands mentioned above. Better results are obtained when advantage is taken of a sand containing a small quantity of alumina, iron, or even alkalis sufficient to make the sand-grains frit and bind together at their angle of rest on the banks of the hearth. Mr. Cosmo Johns considers that the melting point of quartz, as distinct from that of another form of silica—cristobalite—may be achieved in the presence of small amounts of impurities in the sand. He would suggest the following permissible range of impurities*: Al₂O₃ up to 2% or more; Fe₂O₃ up to 0.5%; CaO, 0.5%; MgO, 0.5%; Na₂O, 0.15%; K₂O, 0.15%; if only one impurity were present. If more than one were present, the amounts would be reduced proportionately.

For the detection of small quantities of "impurities" in sands spectroscopic analysis has already proved of great value qualitatively. It is to be hoped that the method will soon be made quantitative. The procedure adopted is to introduce a small quantity of the sand into an electric arc flame, take a photographic record, and afterwards determine the elements present and their relative amount by measurement of the lines, using comparative spectra. The presence and relative abundance of the constituents can be estimated in a much shorter time than it takes to make a chemical

Connection between chemical and mechanical constitution.

In the above two tables, the chemical composition yields definite information as to the properties of the sands and their likely behaviour when used in furnaces. Similarly, in the case of high silica sands used with an artificial "bond" for steel-casting, we can determine their probable value from their chemical composition. When, however, we endeavour to interpret the chemical analyses of such moulding-sands as those with a natural bond, particularly the sands of value to the steel industry, we obtain little information which is of practical utility. It is true we learn that lime, magnesia, potash, and soda, if present at all, should be in small quantity, but we gain little information as to what compounds in the sands are responsible for their success.

Steel-founders have long said that bulk-analyses of such sands are practically useless. As an example, we may quote the analysis of a valuable sand for steel-casting :—

SiO ₂	% 84.7
Al ₂ O ₃	6.85
Fe ₂ O ₃	7.2
CaO	0.1
MgO	0.2
Loss on ignition	3.9
Total	102.95

If, however, a chemical analysis be made of each grade in a sand, we obtain much valuable information. In high-class moulding-sands (with natural bonds), certain grades such as coarse sand and clay are strongly in evidence, others like fine sand and silt are subordinate. Usually the coarse sand is one of the highly refractory silica sands like those discussed earlier in the paper. It is almost entirely composed of quartz-grains, sometimes bearing thin pellicles of ferric oxide. Felspar grains are occasionally seen, but are usually uncommon. Other minerals are so rare as to be practically absent.

Except for certain iron-casting work and for brass-moulding, where smooth surfaces are required, fine sand and silt are practically absent. The clay grade is, however, of the utmost importance. Coarse high silica sand has no bond in it and would not stand up as a face. The clay yields, with the

* Trans. Faraday Soc., Vol. XII., 1917, "Silica as a Refractory Material."

water it adsorbs, the "glue" which holds the coarse quartz-grains together even at high temperatures. A chemical analysis of the clay-grade is therefore very desirable. The clay must be as refractory as possible. Ideally it would be merely silicate of alumina (kaolin), but unfortunately kaolin has no great binding properties. Fireclay itself is occasionally added to silica-sands as a binder.

As indicating the importance of grading in the matter of size and proportion of grains, the following tables are of interest. The most useful classification into grades is as follows:—

Greater than 2 mm. diam.	Gravel.	} Sand-grade.
Greater than 1 mm. diam. and less than 2 mm.	Very coarse sand.	
Greater than 0.5 mm. diam. and less than 1 mm.	Coarse sand.	
Greater than 0.25 mm. diam. and less than 0.5 mm.	Medium sand.	
Greater than 0.1 mm. diam. and less than 0.25 mm.	Fine sand.	} Silt grade.
Greater than 0.05 mm. diam. and less than 0.1 mm.	Superfine sand or coarse silt.	
Greater than 0.01 mm. diam. and less than 0.05 mm.	Silt.	
Less than 0.01 mm.	Clay or mud grade.	

TABLE I.

Some natural moulding-sands for steel-casting.

Mechanical analyses obtained by elutriation: Percentage weights.

	>1 mm.	> 0.5 and <1 mm.	>0.25 and <0.5.	>0.1 and <0.25.	>0.05 and <0.1.	>0.01 and <0.05.	<0.01.	Total sand-grade >0.1 mm.
Belgian sand	—	7.5	64.9	12.0	3.3		12.3	84.4
French sand	—	0.6	18.0	62.7	3.1		15.6	81.3
Cornish Red sand	—	0.6	37.3	42.7	5.7		13.7	80.6
Huttons Ambo sand	—	4.5	57.7	16.0	1.8		20.0	78.2
South African sand	—	0.5	3.4	70.5	1.0	6.3	18.3	74.4

TABLE II.

Mechanical analyses of "mixtures" used for steel-casting.

	>1 mm.	>0.5 and <1 mm.	>0.25 and <0.5.	>0.1 and <0.25.	>0.05 and <0.1.	>0.01 and <0.05.	<0.01.	Total sand-grade >0.1 mm.
Core-sand	6.5	2.5	10.4	57.8	0.3	4.8	17.7	77.2
"Strong" sand	0.4	0.8	15.8	64.7	0.1	2.4	15.8	81.7
Small green-sand work	2.7	2.2	16.8	61.9	0.1	2.2	14.1	83.6
For very large work	36.2*	8.5*	7.7	23.5	1.1	9.3	13.7	75.9

* Contains much clincker.

In each of these it will be observed that the coarse and medium sand-grade is high, and the clay-grade comparatively high, but that the percentage of fine sand and silt is very low. This is an important characteristic of all good moulding-sands. The predominant coarse sand ensures that the mould shall be open, containing adequate pore-space for the free passage of air, vapours, and gases. The clay-grade provides the refractory bond, which, with water, unites the large grains together, but the quantity of clay is of course not sufficient to fill the interstices between the grains (the pore-space is probably about 40% of the whole). Fine sand and silt, which would tend to pack up and fill all the pore-space, are practically missing. Good sands for greensand-moulding are therefore non-graded materials, *i.e.*, they are made up of a mixture of grades and of such different materials as clay and sand. Glass-sands on the other hand should be exceedingly well-graded, as the following analysis of Lynn sand indicates:—

>0.5mm., nil; >0.25 & <0.5, 94.8; <0.1 & <0.25, 4.9; >0.01 & <0.1, 0.2; <0.01, 0.1; total sand-grade >0.1 mm., 99.7%.

	Aylesbury.	Aylesford.
SiO ₂	99.80	99.06
Al ₂ O ₃	0.32	0.56
Fe ₂ O ₃	0.03	0.04

K ₂ O	0.04	0.26
Na ₂ O	none	0.11
Loss on ignition	0.22	0.22

100.41 100.42

Leighton and Lynn sands which, though less pure, are coarser, prove to be much more suitable. Sands with an aluminous bond (kaolin), like that from Huttons Ambo, of value for fettling purposes, are obviously not well-graded. The chemical and mechanical analyses of such a sand are as follows:—

	%
SiO ₂	98.36
Al ₂ O ₃	3.63
Fe ₂ O ₃	1.28
CaO	0.52

98.84

>0.5 & <1 mm., 1.4%; >0.25 & <0.5, 84.9; >0.1 & <0.25, 7.5; >0.01 & <0.1, 4.1; <0.01, 2.1: total sand grade >0.1, 93.8%.

In the case of the red sands of Triassic (Bunter) age, of which Birmingham sand is a well-known example, the clay or mud-grade which serves as a bond is not hydrated aluminium silicate, but ferric oxide. The same character is observed no matter where the sands are found—Birmingham, Stourbridge, Kidderminster, Wolverhampton, Runcorn, Ormskirk, Worksop, Hensall, Heck, Doncaster, Mansfield, Belfast, etc. In all cases there is a thin pellicle of iron oxide around each of the grains of quartz. This iron oxide possesses, to a remarkable degree, the power of holding a film of water by surface tension, and so making a strong bond between the grains. A characteristic property of all good moulding-sands is their water-carrying capacity. Many will hold as much as 10 or 12% of water without being really wet. Some mechanical analyses of these Bunter sands are as follows:—

	>0.5 and <1 mm.	>0.25 and <0.5.	>0.1 and <0.25.	>0.05 and <0.1.	>0.01 and <0.05.	<0.01.	Total sand-grade >0.1 mm.
Mansfield	4.0	30.0	43.75	16.25		6.0	77.75
Birmingham (close)	1.8	40.6	46.0	6.5		5.1	88.4
Compton, near Wolverhampton	0.2	6.5	77.9	7.1	1.3	6.0	84.2
Kidderminster	tr.	33.5	51.8	7.8	4.0	2.9	85.3
Ormskirk	tr.	4.3	77.8	12.6		5.3	82.1
Belfast	0.4	3.0	30.9	50.2		15.5	34.2

and a bulk chemical analysis of that from Belfast is:—

	%
SiO ₂	81.47
Al ₂ O ₃	8.84
TiO ₂	0.35
Fe ₂ O ₃	1.84
CaO	0.86
MgO	0.81
K ₂ O	2.78
Na ₂ O	1.50
Loss on ignition	2.24
Total	100.69

Such sands are used very largely for the casting of iron and brass, and for steel where the conditions are not very exacting, nor the temperature attained very high. There is no danger either of the setting in of reducing conditions which would yield the easily fluxed ferrous silicate if the temperature were sufficiently high.

Mineral composition.

Little need be said at this stage as to the bearing of the mineral composition of sands used in glass-making or metallurgical practice. It has been evident throughout the foregoing remarks that not merely are the chemical elements present of significance, but that their state of combination, i.e., the minerals present, is also important. Zircon (ZrSiO₄), rutile (TiO₂), ilmenite (2Fe₂O₃·3H₂O), and ilmenite (FeTiO₃), among others, are, for example, very harmful in glass-making. The presence of felspar may be a distinct advantage. On the other hand, in sands to be used as refractory bodies, felspar is inimical. Similarly, dolomitic and calcareous sands (containing dolomite [Mg.Ca]CO₃ and calcite CaCO₃) are known to be very objectionable. Chemical analysis is a long and tedious process. The geologist, making a mineral analysis by separating the various minerals of different densities by means of a heavy liquid, such as bromoform, and examining them under the microscope,* can determine at once the suitable or harmful minerals present, and obtain an idea of the qualitative and relative quantitative

chemical composition of the sand. Further, if he should know the mineral composition of British sands and the chief of foreign supplies, he will be able to identify any sample referred to him, or to say whether successive consignments of sand come from the same quarry or bed.

Silica itself exists in sands in several different mineral forms, as quartz, opal, chalcedony, etc., and after the sand has been subjected to high temperatures for considerable time, as tridymite and cristobalite. It is a fact which is the outcome of experience that crushed silicious rocks such as vein-quartz, quartzites, and certain sandstones, do not make as satisfactory glass as ordinary pure sands. The batch containing crushed rocks requires greater heat to bring it into the molten state. Whether this is because of the presence of two allotropic low temperature forms of quartz differing crystallographically and physically, one possibly as a cement, of the different hydration of the silica acting as matrix, or of the presence of certain inclusions in the quartz, is not known.

Apart from the "allogenic" minerals in sands derived from the breaking-down of older rocks, there are also "authigenic" minerals, formed when the sand was laid down or at some subsequent time. Of particular significance in this connection may be the colloidal minerals such as gelatinous silica, glauconite (iron potassium aluminium silicate), etc. Much of the ferric oxide in sands has been derived from the decomposition of ferruginous minerals, and it is noteworthy that some of the most successful steel-moulding sands—with the strongest bond and velvety grip—such as the "Belgian Red" and "Yellow" (Diastian) and "Cornish Red" (Pliocene deposits, St. Erth), owe their colour to iron oxide and are associated with glauconite-bearing deposits. Other important high-silica sands used in casting work, such as those from Leighton Buzzard and Lynn (Lower Greensand), contain seams in which glauconite occurs. Colloidal silica may be in itself an important bond. As we have seen, china-clay or kaolin is also a decomposition product, usually being formed from felspar. The question is one upon which we have very little information, and which will repay the investigator who follows it up. The presence of small quantities of certain minerals may influence to a marked extent physical changes and mineral conversions in sands.

In speaking of sands required for metallurgical practice and glass-manufacture, those used as abrasives should not fail to receive attention. Usually, fairly coarse sands are employed; the rougher the work the coarser the sand used. The sand should be made of a tough mineral, such as quartz, with a very poor cleavage, and while the grains need not be angular, they should not be highly rounded. The sand should be dry and well-graded, so as to slip freely through the feeding-funnel and jet. Aylesbury, Lynn, Leighton, and river sands, besides those from Belgium and Fontainebleau, have been successfully used. Road-grit from roads made of flint is a valuable and effective abrasive, a fact fully recognised by the motorist and cyclist! Almost any "sharp" sand (i.e., well-graded and containing no silt or clayey matter) used in the works for any other purpose is

* Memoir, p. 18.

likely to be of value as an abrasive. In the U.S.A. garnet-sands have been similarly used. The mineral garnet is hard, tough, and possesses a poor cleavage. Artificial products such as carborundum, have in certain directions largely replaced natural products like emery (corundum) and quartz. Natural minerals, such as quartz, which are not too hard, have, however, advantages, as in the grinding of plate-glass.

General observations.

In the above notes an attempt has been made to show quite as clearly what we do not know and in what directions research would be profitable, as to indicate the present extent of our knowledge. The glass-sands of the United Kingdom—their properties, composition, and location, have now, under the auspices of the Ministry of Munitions, been dealt with fairly thoroughly. It is clear that the country can be entirely self-supporting, even in the matter of optical glass. The importance of the inquiry into the resources of such sands, and of the publication of the results, has been testified to by those interested in the industry all over the country. The question of British supplies of refractory sands, especially those used in the steel industry, is, if anything, even more urgent.* Much preliminary research work into the properties of such sands is, however, required before all the suitable supplies can be located. The requirements must first be well-known and an idea obtained of the reasons for the suitability of the good materials.

British resources of high-silica sands for steel-moulding, furnace-fettling, crucible-making, etc., may be dealt with without much further work—most of the best have already been described as glass-sands. The supplies suitable for making silica and sand-lime bricks need investigation. Recent developments have shown that large supplies of sands exist suitable for the former purpose, the successful standard of composition being lower than was expected previously. A complete statement of British resources of moulding-sands with natural bonds is very desirable, especially those of value in such a key-industry as steel-founding. It is only in this direction, if any at all, that the importation of foreign supplies is justifiable.

The production of steel by the Bessemer, or its modification, the Tropenas process, is doubtless declining, and that by the open-hearth process increasing. The demands of the steel upon the sand in the former process, in which very high temperatures are reached, are much greater, whereas few difficulties are experienced in finding sands suitable for casting steel made by the latter process. Natural bonds, too, appear to be passing in favour of such artificial ones as dextrin, flour, treacle, sugar, etc. High-silica sands, of which in Britain we have an abundance, will then come into their own.

Above all, the economic considerations dominate the questions of production. Foreign glass-sands were imported into this country before the war, not merely on account of their supposed superiority of quality, but because they were frequently transported as ballast, and could be delivered at British works at a price much lower than our native sands. The same remarks apply to certain refractory sands. At the present moment, it is not so much the cost as the difficulty of transport which has to be considered: what is the nearest suitable supply of sand to every works? When peace conditions return, the governing factor will again be one of cost, and only by the working of British supplies on an extensive scale, by co-operative action, by careful and up-to-date treat-

ment of the materials, by increasing inland water-transport, and by reduction of railway freights, shall we be able to remain self-supporting as an island Kingdom.

THURSDAY MORNING.

INDUSTRIAL FUEL FROM GAS WORKS.

BY E. W. SMITH, M.S.C., F.I.C.

(Chief Chemist, Gas Department, Birmingham).

The industrial world seems to be at last awakening to a proper appreciation not only of the magnitude and importance of the gas industry, but of its value as a relatively untapped source of fuel of the most useful and nationally efficient kind.

It is generally agreed that the use of raw coal for most purposes is wasteful of one of the most important assets. It is to be hoped that the day will soon come when no coal will be used for any heating processes—whether it be in boiler firing or in the domestic grate. In this country the latter has become a national institution which it is difficult, largely from convention and sentimental reasons, to abandon. The war has still further encouraged the use of other forms of heating and the advantages have been so great that I believe the old prejudice in favour of the coal fire has at last been broken down.

During the year ending March 31st, 1917, the quantity of town's gas made in Birmingham was over eleven thousand million cubic feet, of which nearly ten thousand millions was obtained from the carbonisation of over 800,000 tons of coal. The remainder was carburetted water gas, produced from nearly 5,000,000 gallons of petroleum oil and over 37,000 tons of coke.

Of the gas sold, nearly 80% was used for heating and power purposes, domestic and industrial. Of this over 20% was used in industrial heating processes and nearly 14.0% for motive power. So far this year the gas output amounts to over 11.0% more than in the corresponding period last year, an increase due almost entirely to heating processes.

Gas is not the only type of fuel produced on the works. The 800,000 tons of coal yielded nearly 570,000 tons of coke, of which 16.55% was used for fuel on the works and 83.45% was available for sale, or about 487,000 tons. Over 24,000,000 gallons of tar was also produced, and from it would be obtained benzol suitable for motor spirit and 8 million gallons of creosote suitable for boiler firing, such as is used in the Navy.

The national aim should be so to use the coal supplies that the maximum national value may be obtained. Even if coal distillation were to cost so much that the net value obtained were less than the net value obtained by the direct combustion of coal, the indirect value to the country for home-produced residuals would justify an increased cost, but as a matter of fact it pays to carbonise coal rather than burn it.

The gas industry distils coal for the gas, and the value of the by-products goes to the reduction of the price of gas. The coking industry exists mainly for the production of a special coke, and the by-products reduce the price of coke. There is no necessity for this distinction and there is no satisfactory reason why the gas industry should not produce more blast-furnace coke or more coke-oven gas made available and suitable for town's use. At our Saltley works we have 60 ovens of the Koppers type in which quite excellent blast-furnace coke is produced. The whole of the coke is available for sale, unlike other methods of carbonisation, because the ovens are heated by means of external producers in which inferior

* Since this was written, the systematic investigation of British resources of such sands has been undertaken by the writer at the request of the Ministry of Munitions of War.

cheap fuel is used. The whole of the coke dust produced on these works, for which there is little sale, is being converted after mixture with 70% slack into producer gas for heating the ovens, and about 45 lb. of sulphate of ammonia per ton is recovered as a by-product per ton of dust.

Many gas works find a ready sale for unscreened coke and consequently in those works little "sized" coke is available. In most of the larger works there is a considerable demand for special grades. In Birmingham we have very extensive screening plants. The quenched coke is separated into the following sizes:—

Large coke, 9 in. to 2 in., used for metal melting, boilers, drop-forgings, etc.

Small coke, 1½ in. to 2 in., used for household purposes, drop-forgings, etc.

1 in. breeze—chain-making, blacksmiths' hearths.

Bean breeze—blacksmiths' hearths.

Pea breeze—concrete and blacksmiths' hearth.

Dust—boilers and concrete slabs.

The proportions of each material made depend on the coal carbonised and the particular type of carbonising plant and on the screening plant.

The coke from continuous verticals is smaller, more porous, and dryer than other coke. That from intermittent verticals is denser, harder, and larger. That from stamped charges in the coke ovens is large, lustrous, dense, and hard.

All works make coke dust. There is no consensus of opinion, however, as to what constitutes coke dust. In Birmingham this amounts to about 5.0% of coke made. When sized it has the following composition:—

20%	over screen	9 holes to 1 sq. in.
22.7%	over screen	16 holes to 1 sq. in.
14.6%	over screen	36 holes to 1 sq. in.
7.7%	over screen	64 holes to 1 sq. in.
33.1%	through screen	64 holes to 1 sq. in.

In works where such elaborate screening is not employed the quantity of dust made may in some cases be less than this.

Practically all our boilers are run on coke, and some of them on coke dust. Wherever there is ample boiler capacity and a suitable boiler is available coke dust may be used, but the water evaporated per hour will be reduced. The efficiency of the fuel, however, need not be reduced. The Meldrum type of furnace has been proved quite satisfactory for the purpose. Here there is a deep fuel bed and low forced draught.

I have known the results from the Stirling underfeed boilers working on an inferior slack, to be much improved by the addition of 30% of coke dust. Coke dust alone is of no use where the boilers are being pressed.

Briquettes are comparatively little used in this country, largely because they are too dense to burn without a large amount of induced draught and because of their cost. Results are being obtained now, however, which would seem to indicate that these troubles have been overcome. Briquettes are now being produced which are as hard, but porous, and require little induced draught. In fact they burn readily—without the objectionable dripping of pitch—in an open domestic grate, and give an almost flameless incandescent body of fuel. More should be heard of this fuel in the not far distant future.

Coke contains sulphur, fixed and combustible. That containing less than 0.3% of combustible sulphur is suitable for braziers, and may be used in the "dug-outs" of the firing line in place of charcoal.

About ten gallons of tar is obtained from each ton of coal. The composition of the tar varies with the type of carbonising installation and the condition of temperature to which the distillation

products are subjected. The average quantity of creosote present in the tar may be taken as 30%. It gives on distillation 5% to 200° C., 85% to 300° C., and 15% above 300° C. Its viscosity at 60° F., taking rape oil as 100, varies between 10 and 16. Its specific gravity is 1.04, and when used under boilers one pound of creosote will evaporate 11.24 lb. of water, a result which is nearly twice as good as when coal is used.

Creosote has been used for some time as a fuel oil. There are special oil burners for the purpose which require air pressures from 0.5 lb. to 3.0 lb. per square inch. The temperatures attainable are extremely high and the cost of heating compares favourably with many other fuels. Oil is not, however, so convenient as gas; it is more variable in the results obtained, and the burners are liable to give trouble. Creosote oil makes an excellent fuel for boiler firing and metal-melting furnaces.

Gas, however, is the most important type of fuel produced on the gas works. There is a tendency at the present time to standardise gas quality for all works. Until quite recent years, gas has been made and sold on the illuminating power basis. Now that well over 90% of the gas is used for heating purposes, including the incandescent mantle, the standard is being rapidly changed to that of calorific value.

The standard minimum quality of gas, which most undertakings are adopting by permission of the Government Departments concerned, is 500 B.Th.U. gross. There is nothing to prevent undertakings from providing a much higher value than this; indeed they would have to do so, to ensure never falling below the minimum.

One cannot find from published records what determined this standard of 500 gross—what were the economic and scientific reasons for its adoption. So far it has not been possible to produce such a quality of gas from an average coal alone by the usual methods of carbonisation and purification, and the average works does not possess a blue water gas plant. It is significant that the railway companies are now taking a keen technical interest in the conditions of gas supply. They are large consumers and it has been reported in the technical press that they suggest that there should be a limit to the amount of inert gases allowable in the gas. This may be another effort on their part to ensure a higher standard of gas for calorific value. There is no doubt they would not be satisfied with a good quality blue water gas having a gross calorific value of 300 B.Th.U., even though the inerts amounted to less than those in a good coal gas.

If 500 gross is the standard agreed upon, then unless blue water gas of good quality be used for dilution the inerts are bound to be high. Flame temperatures in this case suffer, and consequently low inerts are necessary to the highest temperature operations, and to incandescent lighting. I have seen cupro-nickel furnaces, taking 250 lb. of metal per heat, worked with blue water gas having a calorific value of 300 gross. The temperature necessary is almost 1700° C. and the B.Th.U. required per pound of metal compared favourably with the B.Th.U. expended when coal gas is used. In normal times the cost of this heat (as B.Th.U.) is about the same in either case. The Heating, Lighting and Ventilating Committee of the University of Leeds and the Institution of Gas Engineers, is now making a study of this question. They are making a very practical effort to evaluate gases of varying quality and composition for various purposes. The range of quality will be a wide one, and the results of their work when co-ordinated with the economic production side, should make it very much easier for the gas engineer in deciding what gas he should make, to give the greatest service to the consumer.

I am of the opinion that gas engineers should carbonise their coals so as to obtain the highest calorific value multiple (make per ton \times cal. value). The dilution of the gas with inerts, whether from the furnaces or by another means, will not affect the multiple appreciably because as the volume of gas made is increased the quality is proportionately reduced. The poorer the quality of gas, however, the lower is the efficiency of extraction of by-products and the costs all round the works and distribution costs will be increased per ton of coal. There is no sense whatever in distributing nitrogen and other inerts. The consumer has a limitless supply of these gases in a more convenient form mixed with oxygen.

So far as possible the gas consumer would naturally like to buy his gas with the precision obtainable when buying electricity. To the consumer extreme accuracy in volume measurement is rather wasted energy when the figures presented do not necessarily have any relation to B.Th.U. supplied. The conditions prevailing during the war on many works, are anything but normal however. There are many factors that militate against the delivery of as good a service of gas as is desirable. Most of the difficulties have been insuperable. After the war, when it is possible for statutory standards to be again observed, then the consumer should have little of which to complain.

I take it as an extremely healthy sign that combinations of railway companies, chambers of commerce, and ratepayers' associations are giving more attention to gas matters, and so far as their interest and criticism is intelligent and well-informed, it cannot but be of enormous value to the industry, although it is to be expected that for various reasons "gratuitous interference" may easily be resented.

Internal versus external producers for retort setting.

It is the usual practice for retort settings to be heated by means of internal producers—that is producers built into the retort setting. For horizontal and inclined retorts this has the following advantages:—(1) The fuel is fed hot from the retort into the producer (this does not hold for vertical retorts). (2) The producer gas passes immediately from the producer into the retort setting, so conserving the sensible heat of the gas for heating the retorts. (3) The radiation losses from the producers may be largely ignored as it is surrounded by the setting to be heated. (4) The capital cost is less than for external producers.

Some of the drawbacks may be stated as:—(1) A large amount of labour is expended in giving the necessary attention to the fires. (2) If poor coal is being carbonised and poor coke being produced, heats suffer and still worse results are obtained than if good heats had been maintained. (3) Heats fluctuate while firing and clinkering, and this is likely to reduce the life of the setting.

The composition of gas produced from coke in an internal producer is:—CO₂, 6.3%; O₂, 0.5; CO, 22.5; H₂, 9.9; CH₄, 1.6; N₂, 59.2%. Calorific value 112 net. Make of gas per ton of coke, 100,000 cub. ft. Tonnage of coke used per ton of coal carbonised, 5.10. Producer gas used per ton of coal carbonised, 10,000 cub. ft. Temperature of producer gases, 850° C. Sensible heat in 1 cub. ft. of producer gas, 29.0 B.Th.U. Therefore total heat in entering setting per ton of coal carbonised is 1,410,000.

If external producers were used making a gas of 130 B.Th.U. net, then 10,850 cub. ft. of this gas would be required per ton of coal carbonised. At 1½d. per 1000 cub. ft., the cost of heating would be 1s. 5d. per ton of coal carbonised.

The cost of internal producer gas would include not only the cost of the coke, but labour, and maintenance, interest and depreciation, supervisory and standing charges, dissectable to the internal producer.

Labour	2.4d.	per ton of coal carbonised.
Coke	24.0d.	" " "
Maintenance	2.5d.	" " "
Int. and dep. 15%	1.0d.	" " "
Total	30.9d. (2s. 6d.)	

This rough computation at least indicates that further trials of external producer gas are justified.

The following should be noted in connection with the external producer:—(1) The capital cost is high. (2) Regulation of heats is simple. (3) There is ample latitude in the type of fuel to be used. (4) If cheap coal slack with over 1% nitrogen is obtainable then sulphate and tar recovery is possible. (5) Once producer gas is available it may be used for electrical generation and excess gas for boiler heating. (6) It releases coke for sale. In some districts this is an advantage.

On our horizontal and continuous working vertical test plants in Birmingham tests have been arranged for external producer heating. Very shortly information will be available on this subject.

Low temperature carbonisation.

This subject has been the topic of many papers and discussions during recent years. There seems to be no general agreement, however, as to the object of commercially developing low temperature carbonisation.

The experimental work of the experienced research chemists indicates the great differences in results obtainable between low and high temperature conditions. Those who have attempted to extend the processes from the laboratory stage to a practical working scale have varied in their aims. Some in the early days have hoped for high benzol yields. Others have expected the high tar yields to justify the process, while still others have had as their main object the production of a solid fuel that would burn easily in the domestic grate without producing smoke.

I think that those who are in closest touch with many of the processes that have been and are being tried agree that so far no really satisfactory results have yet been obtained. This does not mean that there is nothing in low temperature carbonisation. I do not believe there has been sufficient competent research work carried out to enable one to pass an opinion either way. If one judged by the average published results no more would be heard of the process.

The saving in freight brought about by the introduction of a centralised low temperature power scheme at the pit mouth is now recognised to be a delusion. The solid fuel produced will occupy a much greater bulk than the original coal, will stand less handling—unless briquettes are made of it, and this is not yet a practical scheme—and the fuel will have to be distributed to many small domestic consumers. If this fuel were completely gasified at the pit it would be better, but it is doubtful whether there would be a sufficient outlet for the power produced except from a uselessly small plant.

In any case the energy in the coal gas is very much less than that from high temperature carbonisation, and it is doubtful whether the financial return from the washed tar oils will be a sufficient justification for the process.

The Government should initiate a scheme for putting the best brains and experience into the subject. Chemists and engineers with wide carbonising experience should be given the subject to work out to a conclusion.

The experience gained in the past by others should be pooled and dissected. It is extremely doubtful whether any of the present suggested retort installations are likely to be satisfactory.

DISCUSSION.

The PRESIDENT said it was with satisfaction that he was able to say that one of the activities of the new Department of Research would be in the direction of investigations similar to those which Mr. Smith had suggested. The Fuel Board of that Department had decided that it was a matter of national importance that experiments should be made which were absolutely unimpeachable in their accuracy. Under the present conditions it had become the duty of the State to see that the fullest possible information with regard to the utilisation of the fuel resources was made available for the nation at large. To-day negotiations were in a fairly forward state with regard to the appropriation of the land for the purpose and for the erection of the necessary works.

Professor HENRY LOUIS asked the author if, instead of giving the screening sizes in so many holes to the inch he could give the diameter of the mesh. The most important point which had been raised was the need for so dealing with fuel as to get the maximum value out of it, but they must be very clear what was meant by that value. It could be taken from a great many points of view. It was conceivably possible to treat coal so as to get the maximum pecuniary value from it and yet not treat it in such a way as to get the maximum benefit for the nation at large. It was also possible to treat coal so as to get the maximum power value but not to secure the maximum value possible. It was an enormously difficult question for there were so many different factors which were not fixed factors but necessarily varied from time to time. He was pleased to hear that the briquetting of coal slack was receiving serious attention. He had been urging on the authorities the fact that this was the time for pushing forward with it. Patent fuel had not found favour in this country to the same extent that it had on the Continent, probably because there was good coal at a cheap rate in England. There were a number of works making patent fuel, but probably three-quarters of this was exported, very little being used in the country. It was probable that coal depôts would be established at the large centres of consumption, and the large quantities of dust which would accumulate at these depôts should be utilised by setting up patent fuel factories. Pitch was not dear, and the wastage of coal and coke dust which was now going on could easily be prevented if energetic steps were taken in that direction.

Mr. W. J. A. BUTTERFIELD agreed with the author that one of the most important points to be considered was the question of the quantity of inert gases in a public gas supply. It was a sign of the healthy condition of the gas industry that there was now an inquiry from within as to that question, and he thought they might anticipate that before long the gas industry would recommend gas undertakings on their own initiative to keep the quantity of inert gas within reasonable bounds. One of the most prominent gas engineers in the country had for years past made it a practice in his own works to keep the inert gases within a limit—he believed it was of 10%. That perhaps was rather a lower limit than many gas undertakings which used water gas were prepared to accept, but some such limit, perhaps 2% or even 5% higher, should surely be recognised as the maximum permissible. Where water gas was used in public supplies, it should be used in approximately uniform

proportions. It was an intolerable nuisance to consumers to have one day 5% or 10% of water gas in the mixture and another day 50%, yet there were some districts in the country where that state of things prevailed. Many consumers would rather pay considerably increased prices for the gas provided they could secure uniformity. He was pleased to hear that coke briquettes were a greater success than formerly. That arose particularly in connection with low temperature carbonisation, because the coke produced was so extremely bulky that the transport cost was much higher for the same fuel value than for coal. It might be possible to deal with this by pulverising and briquetting it so as to get fuel which would have some of the compactness and density of coal. In considering the question of low temperature carbonisation it must be borne in mind that the value of the products was chiefly their fuel value. Very few of them having a value for any other purpose could have much effect upon the ultimate results. That being so, it was a question whether raw coal could be burnt to the same advantage as the gas, coke, and tar resulting from carbonisation. Any saving in the fuel value obtained in the briquettes must be more than the fuel expended in the plant used.

Mr. J. DRUMMOND PATON pointed out that it was not possible to treat every coal on the same basis. There were millions of tons of coal in this country which would never be used until low temperature carbonisation came into operation. It was impossible to coke a resinous coal or burn it in a furnace, but it could be utilised by a low temperature process. He submitted that the question to be settled was the relative value of low temperature and high temperature work with various coals. They were moving in the direction of a higher recovery of products, and coal oil was one of the most valuable assets of this country. Enormous quantities of this oil could be obtained by low temperature distillation from coal left in the mines to-day. He called attention to the valuable investigations of Mr. Thomas Lomax, of Bolton. It was not possible to briquette coal having a high ash content for domestic purposes. Coal containing 20 to 30% of ash could not be briquetted, but it might be gasified. Regarding Commissions, he suggested that when such bodies were appointed they should consist of men who were conversant with the subject under consideration.

Mr. SMITH, in reply, said that a Government department was taking up this question of utilisation of coal from the point of view of complete gasification. The briquetting system he had referred to was not being developed in Birmingham. Briquettes were being tried in the city, but the system was being developed in Lancashire. He had no intention of casting any reflection on the bonâ fides of those who were experimenting with low temperature carbonisation, but he regretted that more work by properly qualified people was not available. In briquetting low temperature fuel for domestic purposes a cost of 5s. 6d. per ton for briquetting had to be overcome, so the fuel must be fairly low priced.

Mr. F. R. O'SHAUGHNESSY said that they were being embarrassed at the Birmingham sewage works by the enormous amount of waste which was sent there, particularly in the shape of tar. This had increased very largely since the outbreak of war, owing to the great growth of small plants.

Mr. SMITH replied that he supposed producer plants were in question and it was to be hoped that the by-products were being satisfactorily recovered.

THE CALORIFIC VALUE OF INDUSTRIAL GASEOUS FUEL.

BY W. J. PICKERING

(Central Laboratory, City Gas Department,
Nechells, Birmingham).

[ABSTRACT.]

The chief object of this paper is to indicate briefly the results of several years' experience in testing gas for calorific value at Birmingham, and to describe the apparatus and methods at present adopted for this purpose.

It has been rightly pointed out by several authorities that the "gross" calorific value given by many calorimeters is not the real "total heating value," owing to the effect of certain atmospheric conditions, as low humidity, etc.

For industrial purposes it will be sufficiently precise to define the "Total heating value" of a gas as "the number of British thermal units produced by the combustion, at constant pressure, of the amount of the gas which would occupy a volume of one cubic foot at a temperature of 60° F., if saturated with water vapour, and under a pressure equivalent to that of 30 in. of mercury at 32° F. and under standard gravity, with air of the same temperature and pressure as the gas, when the products of combustion are cooled to the initial temperature of gas and air, and when the water formed by combustion is condensed to the liquid state." [See Circular No. 48 of the United States Bureau of Standards—"Standard Methods of Gas Testing."]

Apparatus employed in testing.—The method of testing must be neither too long nor the apparatus too complicated, so that a junior assistant can readily carry out a test at any required time in, say, ten minutes, with a margin of error of 1%.

The "flow" type of calorimeter is generally used. "Flow" calorimeters are of two classes: (1) those in which the paths of travel of products of combustion, and water, are relatively short and parallel; and (2) those in which the stream of water flows in a long tube, arranged as a spiral, round which the products of combustion pass slowly.

The calorimeter in general use at Birmingham is of type (1), and the Boys instrument, as prescribed by the Metropolitan Gas Referees, is the best known in class (2).

Up to the commencement of the present war, the Junkers calorimeter had been adopted for many years, at Birmingham, as the best instrument for technical work; but after 1914, as the supply from the Continent had necessarily ceased, a calorimeter of similar pattern but with alteration of several points in the design, tending both to greater accuracy of result and longer life of the instrument, was constructed. Under the supervision of Mr. J. Turnbull, Superintendent of the meter shops at the Windsor Street Works of the Birmingham Gas Department. The cost of construction, even in war conditions, has proved considerably less than the price of the German-made calorimeter. Fig. 1 illustrates the Birmingham instrument, which is made chiefly of 20 B.W.G. tinned copper. Improvements have been effected, as compared with the German design, in the life of the instrument, by using slightly heavier gauge metal in the internal parts exposed to the action of the products of combustion, and in the accuracy of the results obtained, by improving the device for mixing the water before it reaches the bulb of the outlet thermometer.

The water supply is led first to the overflow reservoir, A, or "constant head," and is adjusted so that when the proper flow through the calorimeter has been arranged the overflow pipe B is working slightly. The water travels down the pipe C to the quadrant regulating cock, D, whence it passes

over the bulb of the inlet thermometer. It then travels down a flattened pipe, E, to the base of the calorimeter body and ascends the annular space immediately adjacent to the chimney, in spiral fashion, the motion being determined by means of a continuous strip of metal arranged as a spiral with 2 inches "pitch." On arriving at the top the water passes outwards, via four short horizontal tubes, F, into the space above the conical top of chimney, where it receives the full heating effect of the products of combustion. It then passes upwards through a specially constructed series of baffle plates, G, which ensure thorough mixing of the heated water before reaching the bulb of the outlet thermometer. After the latter has been passed, the water enters a special overflow outlet, H, from which it flows to the "change-over" funnel and so into the collecting vessel or to waste.

Birmingham Junkers calorimeter.

FIG. 1.

The gas is burnt centrally within the chimney in a special Bunsen burner, I, fitted with air regulator, stop tap, and cone injector with needle valve capable of adjustment so as to pass up to 15 cubic feet of gas per hour at 7- to 8-10ths inch pressure (water gauge). The products of combustion pass up to the conical dome of the chimney and are then diverted downwards through an annular waste gas flue, J, having division walls arranged vertically and radially $\frac{1}{4}$ inch apart. On reaching the base of the instrument they enter a common collecting flue, K, which carries a waste gas thermometer and special baffle plate, L. The condensed water from the waste gases falls into the bottom casting of the instrument and drains through the drip outlet, M, into the collecting tube or to waste. The thermometers for measuring the temperature of inlet and outlet water are specially calibrated, by comparison with a standard thermometer specially checked by the National Physical Laboratory, and a correction card made out for each giving corrections to be applied for every 2° rise in temperature from about 6° to 46° C. These thermometers are read, by means of

small telescopes attached to the stem of each, to the nearest 0.01° C.

Between the body of the calorimeter and the outer case, there is an annular air jacket, about in. in width, which prevents loss of heat from the calorimeter to the atmosphere. The instrument is readily adapted to the testing of low grade gas, or producer gas, by adjustment of the cone valve injector on the burner in such a manner that the rise in temperature of the water flowing through the instrument is kept at about the same figure.

The calorimeter prescribed by the Metropolitan Gas Referees has been designed by Professor Boys, and its latest pattern is illustrated and described in the Notification of the Gas Referees for the year 1916. The description is reproduced in the Gas World Year Book.

The Boys calorimeter may quite easily be adapted for testing producer or low-grade gas, such as Mond gas, by fitting special flat flame burners to pass gas at a greater rate, such that the normal temperature rise of the water flowing through the calorimeter may be maintained.

In addition to the calorimeter itself, whether of class (1) or (2) type, the following equipment is essential for the proper carrying out of the test :—

1. *A proper supply of water of uniform temperature*, the latter being, if possible, only slightly below that of the atmosphere of the laboratory. An overhead tank, of about 30—50 gallons capacity with ball-cock feed from town supply, and overflow pipe, is very useful in this connection.

FIG. 2.

2. *A divided funnel for quickly diverting water* flow from calorimeter to collecting vessel or waste. This, which is sometimes attached to the calorimeter itself, tends to reduce the personal error in reading.

3. *A collecting vessel, for receiving water from calorimeter*. This should be accurately graduated, on the neck, in divisions representing 10 c.c. The vessel used for this purpose at Birmingham is a 6 to 5½-litre flask, strongly made, with long neck or graduations. All flasks used are calibrated in the laboratory.

4. *A graduated cylinder for measuring the condensed water from calorimeter*. This should be of narrow bore, a convenient arrangement for this purpose being the "Eggertz" carbon tube, cut off to suitable lengths, and mounted in a simple foot for quickly adjusting its position below the calorimeter.

5. *A primary governor on the gas supply*. Where gases at various pressures have to be tested on one set of apparatus, it is essential to have a primary governor to reduce the pressure to proper limits.

A mercury governor of the "Stott" type is satisfactory for such work.

6. *A secondary governor on the gas supply* is essential to keep the pressure of the gas at inlet to test meter uniform. The Gas Referees' type of balance governor answers best.

7. *A test meter, fitted with Fahr. thermometer*, making 1 revolution per 10 cubic foot of gas passed, with dial divided into 100 parts and each 0.01 position marked.

8. *A small diaphragm governor*, on the outlet of the meter, takes up any slight oscillations in pressure due to wave motion of the water in the meter.

9. *Pet-cocks*, for attaching pressure gauges, at inlets of the primary governor, secondary governor, meter and calorimeter.

10. *A hygrometer*, of the Gas Referees' pattern, for taking the humidity of the air of the room.

At the right-hand end of the calorimeter bench at Birmingham, below the water tank, is arranged a battery of gas services, each of which may be connected to either or both of two calorimeter sets by means of flexible metallic tubing with winged-nut ends. In order to ensure that the actual gas from a collected sample or stream of gas goes through to the calorimeter, a special battery of gas connections has been installed, and each gas, before testing, is connected to the inlet of a rotary meter the outlet of which, fitted with pressure gauge and regulating cock, is connected by 1½-in. pipe to the main going to the inlet of the works exhauster.

By this arrangement, as shown in Fig. 2, a "pull" of 15 to 30 tenths of an inch is utilised to draw the gas quickly from the sample holder or works main to the inlet of the testing apparatus, the regulating cock (Fig. 2) being adjusted in the case of each gas so that 1 inch pressure is maintained on the adjacent gauge. After the proper volume of gas has been "pulled-over," a few minutes will suffice to burn through to the calorimeter before proceeding to test.

Given satisfactory conditions of apparatus the test may be carried out and the result arrived at in 8 to 10 minutes from the commencement of the test.

Errors in testing. The results obtained in Birmingham by the method just described, are sufficiently accurate for modern industrial purposes.

Data from actual tests suggest that it is unnecessary to apply corrections for atmospheric humidity and other disturbing factors.

In the technical press in February last* were published the instructions for "Determining the Heating Value of Gas," as elaborated by the Paris Municipal Lighting Laboratory and approved by the Prefect of the Seine. The calorimeter used is apparently an old type Junkers, with inlet and outlet water thermometers at different levels, and is not so convenient in use, for this reason, as the Birmingham pattern.

No mention is made of a correction for humidity conditions, but among the corrections is one for the pressure of gas at the meter, which is not usually made in this country. The pressures obtaining in the sets of apparatus at Birmingham are, on an average, as follows :—

Inlet test meter : 20/10°, water gauge.
Outlet " " : 16/10°, " "
Inlet calorimeter : 8/10°, " "

Assuming 18/10° pressure of gas at the meter, this amounts, if neglected, to —0.4% error in the corrected gas volume, or a result which is 2 B.Th.U. high for a 500 B.Th.U. gas. This correction is hardly worth the extra labour involved in making it.

Our aim in Birmingham has been to reduce both

* "Gas Journal," 137., p. 202.

apparatus and method of calculation to the simplest or most easily understood conditions, so that the large number of tests of this kind carried out at various periods of the 24 hours can be satisfactorily made by a junior chemist. We do not claim that our method is either perfect or "fool proof," but it is sufficiently accurate for modern industrial requirements.

The heat efficiency of the calorimeter used is admittedly as high as in any of this class, and in the absence of any really reliable method for easily standardising gas calorimeters, we have adopted the plan of frequent comparison tests, which should agree to within 3 B.Th.U., when a collected sample of "straight" coal gas is well "burnt through" on both calorimeter sets.

If the results differ by more than 5 B.Th.U., when the rest of the apparatus (meter, etc.) has been carefully verified, the calorimeter giving the lower result is carefully overhauled, it being contended that the higher figure must be the more correct one.

It is worthy of note that a new calorimeter requires to be run for about 24 hours before the results obtained reach a maximum figure. This would appear to be due to the time necessary for the surface of the waste gas vertical flues to assume a certain physical condition which ensures the necessary time contact for proper cooling to take place.

Recording calorimeters. The perfect recording calorimeter has yet to be placed on the market, but the instruments at present available are extremely useful as a guide to fluctuations in quality of the gas on a works "stream." The readings cannot be taken as absolutely correct, but require to be regularly and frequently checked by actual tests in order to maintain a fair degree of accuracy. Special precautions must be taken to screen the instruments from draughts and from exposure to direct sunlight, otherwise the record may develop serious error.

Of the type which indicate the "net" value of the gas, the most satisfactory appears to be the Beasley Recorder, as made by Messrs. Parkinson and W. and B. Cowan, Ltd., of Birmingham. This instrument is in fairly extensive use in the Birmingham Works. It is constructed in two types, one being used for coal and town's gas, with a chart range of 300 to 700 B.Th.U., and the other for Mond or producer gas, with a chart range from 50 to 250 B.Th.U. The gas is burned within a well-radiating chimney, and the working of the calorimeter depends upon the fact that the average rise in temperature of this chimney is proportional to the heat developed by the flame.

A recording calorimeter which would give a continuous record of the "Total heating value" of the gas would undoubtedly be a valuable instrument, especially in large works. Such an instrument will very probably be placed on the market in the near future in this country. Its cost would necessarily be higher than that of the "net" value recorder, but its accuracy and sphere of usefulness should more than outweigh this. Before the war, practically the only type of "gross" value instrument had to be obtained from Germany. Let us hope that this will not be so in the future.

In conclusion, the author wishes to thank the Birmingham Gas Committee for kindly granting permission for this paper to be given, and also his chief, Mr. E. W. Smith, for helpful facilities afforded him during its preparation.

SOME SOURCES OF BENZENE AND TOLUENE FOR HIGH EXPLOSIVES.

BY T. F. E. RHEAD, M.Sc. (CENTRAL LABORATORY, BIRMINGHAM GAS DEPARTMENT).

Although a large amount of the information obtained during the war concerning the production

of benzene and toluene has not been published, for obvious national reasons, it is hoped that a review of such work that has been described in the technical press will be found both useful and opportune.

By way of introduction it will be recalled that Michael Faraday is usually credited with the discovery of benzene in 1825 while investigating the liquids condensed from the thermal decomposition products of fish and vegetable oils for gas making and called by him "bi-carburet of hydrogen." The Germans, however, claim to have discovered it forty years before Faraday.

Toluene was discovered in 1838 by Pelletier and Walter in the condensation products from the manufacture of rosin gas and called "resinaphtha." Deville obtained it later by the distillation of "tolu balsam" and Berzelius named it toluene.

The preparation of synthetic phenol, and its subsequent nitration to picric acid, which has been successfully worked out on a commercial scale during the war, caused the great demand for benzene as the starting point of this process. The phenol used previously was obtained from coal tar, but synthetic phenol, being much purer, is far more satisfactory.

The trinitro derivative of toluene, T.N.T., was little known in this country three years ago, but the comparative safety with which it can be manufactured and handled and its excellent explosive properties caused an urgent demand for it, and consequently for the toluene from which to make it. The history of the Allies' success in producing this German explosive will, when written, be one of the most interesting romances of chemical industry.

The value of benzene and toluene for producing high explosives depends on their purity. Benzene is fairly easy to purify because it freezes at 4° C., but such is not the case with toluene, which only freezes when cooled to -90° C. Particularly troublesome impurities in some brands of toluene are those paraffin hydrocarbons which are neither removed by sulphuric acid washing nor by fractional distillation; such impurities complicate the nitration process and make it more expensive. However, when the supply of toluene was unequal to the demand, both the pure and paraffinic varieties were used for making T.N.T., but since the sources of the pure substance have themselves become sufficiently developed, the paraffinic product and likewise the processes producing it have apparently been less profitable.

The various sources of benzene and its homologue toluene can be classified as follows:—

- (1) Synthetic, catalytic, and electrical processes.
- (2) Certain crude petroleum products containing them in the uncombined state.
- (3) The destructive distillation of coal.
- (4) The thermal decomposition or "cracking" of petroleum oils.

The methods under group (1) do not appear to have advanced much beyond the experimental stage.

In 1899 T. B. Jacobs prepared benzene along with other hydrocarbons by heating a mixture of finely divided metallic carbide and a fusible metallic hydroxide in equivalent molecular weights up to the melting point of the hydroxide.

Fischer and Niggeman (Ber., 1916) describe some work wherein they boiled xylene with 2 to 4% of aluminium chloride for two hours beneath a reflux condenser and obtained 12% of toluene with a certain proportion of benzene and of higher homologues of xylene. The method gave negative results when solvent naphtha (distilling 2% at 140° C.) was used.

Scholiren in 1901 prepared benzene and its homologues by electrolysis. According to him, when coal, tar-oils, or other carbon compounds are exposed to a direct electric current in a porous

cell or to an alternating current in any sort of vessel in the presence of water and soluble or insoluble acids, bases, or salts (inorganic or organic) first benzene and its homologues and subsequently their hydroxyl compounds are formed. Only very weak currents are required for the reaction and the temperature has but little influence on the process.

Just prior to the war a Swedish engineer patented an electrical process for extracting benzene from coal at a lower cost than by other methods and giving a pure product.

Uncombined benzene and toluene in crude petroleum. Some years ago the idea was prevalent that benzene and other aromatic compounds could only be obtained in quantity from coal distillation products, but it is now well known that crude petroleum from certain districts contain considerable amounts of these substances and this source proved of very great value when the shortage of benzene and toluene was serious. The submarine peril has presumably endangered the reliability of this supply and it is gradually giving way to that obtained from coal. Moreover, the toluene obtained from crude petroleum has a high paraffin content, which is another drawback.

At present by far the most important source of these two hydrocarbons is that of the carbonisation of bituminous coals, and under suitable conditions, very pure products are obtained.

The mode of formation of benzene and its homologues during the thermal decomposition of coal is very incompletely known, and possibly a brief résumé of the present state of our knowledge on this problem will be useful at this juncture.

Evidence seems to show that benzene and its homologues are not primary thermal decomposition products of coal but owe their formation to polymerisation and secondary reactions among the primary products while the latter are exposed to the requisite conditions.

Benzene hydrocarbons produced during coal distillation seem to be formed by three main groups of reactions: (1) Condensation of olefines; (2) dehydrogenation of corresponding naphthenes, and (3) the polymerisation of acetylene.

Olefines, naphthenes, and acetylene appear in the low temperature or primary decomposition products of coal.

Burgess and Wheeler (Chem. Soc. Trans., 1914, 105, 131), distilling coal in a vacuum up to 450° C., were unable to detect any benzene hydrocarbons in either the liquid or gaseous products.

Jones (this J., 1917, 36, 3) has analysed the tar obtained in the above investigation and found it to consist of (1) unsaturated hydrocarbons, (2) naphthenes, (3) liquid paraffins, (4) phenols and xylenols, (5) aromatic compounds (homologues of naphthalene), (6) pyridine, (7) traces of a solid paraffin, but benzene and its homologues were absent. From the results of the thermal decomposition of this tar at different temperatures, Jones concluded, among other things, that benzene and its homologues are chiefly formed as the result of olefinic condensation at temperatures of 700° C. and upwards. To some extent they are products formed by the thermal dehydrogenation of the corresponding naphthenes. Jones (Chem. Soc. Trans., 1915, 107, 1582) had previously found that the cyclo-hexanes decomposed at 490°—510° C. over hot porcelain and formed the gaseous products hydrogen, methane, ethane, ethylene, and traces of acetylene and considerable quantities of benzene.

If the necessary naphthenes predominated in the primary products of coal distillation, a temperature of 500° C. upwards would give the maximum yield of benzene hydrocarbons, but apparently the olefines predominate because the maximum benzene yield is obtained at 700° C. upwards.

The once prevalent view that acetylene was the basis of aromatic formation during coal distillation is now discredited, but it seems quite probable that an appreciable quantity of benzene is produced by the polymerisation of this hydrocarbon, which appears among the primary products of the thermal decomposition of coal.

According to Burgess and Wheeler (Chem. Soc. Trans., 1910, 97, 1917) gas obtained from bituminous coal distilled at different temperatures over a range 450°—1000° C., contained 0.5% acetylene. In another of their papers (Chem. Soc. Trans., 1914, 105, 131) they record having obtained acetylene from coal, at a temperature as low as 300° C., equal to 0.55% by vol. of the gases, while at 340° C. the gas contained 0.75% and at 400° C. 0.6%.

Bone and Coward (Chem. Soc. Trans., 1908, 84, 1201) in their work on the thermal decomposition products of hydrocarbons, state that acetylene at comparatively low temperatures exhibits a strong tendency to polymerise forming benzene, etc., so that whenever acetylene is a primary product in the decomposition of another hydrocarbon (for example, in the case of ethylene) there is always a marked secondary formation of aromatic hydrocarbons, including benzene, at low temperatures. This tendency to polymerise reaches a maximum probably somewhere between 600° and 700° C., after which it diminishes rapidly as the temperature rises and is but little in evidence above 1000° C.

It is interesting to note that Bone and Coward found that acetylene partially polymerises and partially decomposes at 480°—500° C. Ethylene decomposes fairly rapidly at 570°—580° C., and gives principally acetylene, together with methane, hydrogen, and aromatic hydrocarbons, including benzene. Ethane decomposes fairly rapidly at 675° C., and gives hydrogen, methane, acetylene, naphthalene, but no benzene.

There is as yet no evidence to show which part of the coal substance provides the benzene-forming compounds, but while it seems likely that the resinous constituents of bituminous coals provide most of them, there is reason to believe that the humic constituents may also aid in the process, though to a much less degree.

Jones and Wheeler (Chem. Soc. Trans., 1915, 107, 1318) resolved a bituminous coal into three portions: (a) insoluble in pyridine, (b) soluble in pyridine but insoluble in chloroform, and (c) soluble in chloroform. These separate portions were thermally decomposed *in vacuo*, the temperature being taken to 450° C. They apparently did not detect any benzene, but the gases from (a) and (b) gave very similar analyses, showing about 60% by volume of paraffin hydrocarbons and 5% of ethylene, whereas the gases from (c) contained 88% of paraffins and 2% of ethylene. The authors conclude from these results and previous work that the portions (a) and (b) consist mainly of the "humous substances" in coal and that (c) represents the "resinous substances."

The high paraffin content of the above gases from (a), (b), and (c) points to the possibility of benzene being formed if these gases were "cracked" at higher temperatures, because, according to Egloff (Met. and Chem., Eng., 1917), and others from their work on oil cracking, all paraffin hydrocarbons except methane will give benzene and toluene under suitable thermal treatment. Moreover, the phenolic bodies which were produced from (a) and (b), but not from (c), would yield benzene when passed over hot carbon (*vide* Watson Smith; Chem. Ind., 1891, 77).

The foregoing résumé points to the conclusion that the temperature 700°—750° C. is the most satisfactory for coal carbonisation when a maximum yield of benzene and its homologues is desired. However, the period of heating of the primary

products, or in other words the "time of contact," plays an important role. If the rate of a particular reaction is slow at a certain temperature a long time of contact will be necessary to complete it, whereas at a higher temperature a much shorter time would be necessary.

It is common in the gas industry to state that high-temperature carbonisation favours benzene production, but it is because the charges in the retorts take up heat so slowly and the retort material conducts heat so badly that it is necessary to have a high temperature (1250° C.) on the outside of the retort to force the heat through the contents in a reasonable time. Cobb and Hollings (J. Inst. Gas Eng., 1914) showed that 5% of benzene mixed with 47.5% of methane and 47.5% of hydrogen when passed over red-hot coke at 800° C., was unaffected, but the benzene was rapidly and totally destroyed at a temperature of 1100° C. It is very probable, therefore, that much of the benzene produced in coal carbonisation is destroyed by contact with the hot sides of the retort.

The products formed during the industrial carbonisation of coal depend on the following factors:—

- (1) The temperature of carbonisation.
- (2) The thermal conductivity of the carbonising mass.
- (3) The chemical and physical composition of the carbonising mass and also its quantity and physical condition.
- (4) The degree of cracking to which the primary low temperature products are submitted before leaving the retort.
- (5) The influence of foreign bodies like iron and lime on the chemical reactions.

The products formed in any carbonising system have been subjected to a greater or lesser degree of cracking according to the position in the retort where they originated. For the same reason the products from different systems vary even with the same coal. For example, in the case of horizontal settings, the primary gaseous decomposition products which are produced, as the charge gradually heats up, are modified according to the time they have to spend in the retort in contact with the hot walls and coke. Products formed near the ascension pipes are subjected to very

from the existing sources, and then of investigating and encouraging possible new sources.

The gas and tar from coke-oven recovery plants and a small proportion of gas works tar supplied us with all the benzene and toluene we required prior to the war and much was sent to Germany in part payment for the German recovery plants set up in this country. A large and little-known field of supply was town's gas, which often contains 30 to 40 times the amount found in the tar.

In the years immediately preceding the war the high price of petrol had focused attention on benzol as a possible substitute, and several people had advocated washing this body out of town's gas.

Doherty, an American engineer, had urged the possibility in this country of recovering 2½ gallons per ton of coal carbonised for gas manufacture. However the antiquated illuminating power standard prevented this procedure. The war demand put a new aspect on the problem, and a large and increasing proportion of town's gas is now being washed for these valuable products.

It became a matter of much import to know which system of carbonisation gave the best yield, and although it is impossible to lay one's hands on reliable comparative data, the order of importance is, roughly: Horizontals, inclined, coke ovens, intermittent verticals, and continuous verticals.

One great difficulty in solving this and allied problems has been the lack of a rapid, simple, and reliable test for the benzol content of a gas, and there is still much room for improvement in this test. It was early discovered that the benzol content of gas from continuous verticals was poor and high in paraffin content and consequently not profitable to wash.

Many experimenters, encouraged by the Ministry of Munitions, worked on processes which were intended to increase the benzol content of coal gas. Experiments were carried out at the Birmingham Gas Works by Mr. E. W. Smith (J. Gas Lighting, 1916.) on the effect of carbonising along with the coal such substances as coal-tar pitch, Mond gas pitch, petroleum residue, and bitumen in horizontal gas retorts. The results with respect to the production of benzol and toluol are contained in the following table:—

	Coal.	Coal + coal tar pitch.	Coal + Mond gas pitch.	Coal + petroleum residue.	Coal + bitumen.
Medium quality gas making coal.					
Nature of coal					
Percentage of pitch, etc., in mixture ..	100.0	4.23	4.25	3.84	4.03
Gallons Benzene per ton mixture	1.659	1.669	0.947	0.905	0.716
do. Toluene per ton mixture	0.4	0.460	0.387	0.538	0.550
do. Benzene per ton pitch	—	0.89	8.64	8.94	4.78
do. Toluene per ton pitch	—	0.35	—	3.70	4.19
Rich South Yorkshire coal.					
Nature of coal					
Percentage of pitch, etc., in mixture ..	100.0	1.20	3.52	5.05	5.57
Gallons Benzene per ton mixture	1.438	0.09	0.514	0.239	2.040
do. Toluene per ton mixture	0.596	0.518	0.70	0.524	0.646
do. Benzene per ton pitch	—	—	0.40	—	2.77
do. Toluene per ton pitch	—	—	1.87	—	1.38

little cracking and pass away very slightly altered—they are really low-temperature products and their proportion to the total products depends on the size of the coal charge. In the case of continuous vertical retorts, where the primary products are subject to comparatively little heat treatment, they pass away without much modification and the chance of benzene formation is less than in the case of horizontals.

Meeting the demand for toluene and benzene. When the urgent demand for toluene and then benzene had to be met, the Ministry of Munitions took the logical course of increasing the supply

As indicated in his paper the coal gas pitch—a high temperature product—does not give much increase in benzene and toluene, being already severely cracked, but the other three do materially increase the benzene and toluene content. However, as only a small percentage can be carbonised at a time it is not profitable to work the process for benzene hydrocarbon production.

Rollason, Stevenson, and others (J. Gas Lighting, 1916) have tried the effect of carbonising the coal along with lime or limestone, and claim that the latter acts catalytically and increases the yield of benzene, but further data are required to sub-

stantiate this claim. Experiments have also been carried out in passing inert gases and steam through gas retorts during carbonising, in the hope of increasing the benzene yield by preventing its being thermally destroyed after formation, but little information is to hand as to the value of this method.

The various low temperature systems of carbonisation, introduced by the Coalite Co.—using a temperature of 400°—500° C.—produce no benzene, etc., but in the new coalite process employing a temperature of 650° C., a yield 1.5 to 2.0 gallons of benzol per ton of coal carbonised is claimed (J. Gas Lighting, 1912).

Cracking of petroleum oils. It has long been known that various oils, especially those in crude petroleum, when subjected to the right conditions of temperature and pressure, break down or polymerise and yield a certain proportion of benzene and its homologues, the amount of which varies with the composition of the oil.

The mode of formation of benzene, etc., during the cracking of petroleum oils is parallel to that of its formation from the cracking of the primary decomposition products of coal. These latter contain many compounds found in petroleum, such as naphthenes, paraffin hydrocarbons, olefines, etc., and since it is far easier to separate petroleum into simple groups of compounds than is the case with coal, a systematic study of the thermal decomposition products of petroleum oil fractions should throw much valuable light on the mechanism of coal carbonisation.

In Russia it has long been the practice to crack petroleum oils to obtain benzene and other aromatic compounds for the dye and explosives industries, the shortage of coalfields made such an industry of vital economic importance. Moreover, Russian petroleum, being rich in naphthenes, lend themselves admirably to benzene formation. There is little doubt that that this industry, founded by the Russian chemists, led by Nikiforoff, has received a great impetus from the needs of the war.

The first systematic work in the modern era, on producing aromatic hydrocarbons from petroleum, was carried out by Rittman (Met. and Chem. Eng., 1915), but the large-scale installation put down at Pittsburgh as a result of his experiments has been unable to compete with other sources of benzene and toluene owing to the small yield and poor quality of the products.

American chemists are working out the mechanism of oil cracking in a very careful manner, and much valuable work has already been done on the effect of temperature, time contact, pressure, nature of the original oil, etc., by Rittman, Egloff, Moore, Twomey, and others. Egloff (Met. and Chem. Eng., 1917), from his own researches and others', draws the following conclusions as to the production of benzene, toluene, and xylene from petroleum:—

(1) All groups of paraffin hydrocarbons have formed benzene and toluene on the thermal treatment, with the one exception, methane.

(2) We can control the yields of aromatic hydrocarbons so as to form benzene, toluene, xylene, naphthalene, or anthracene in maximum quantity.

(3) The group of paraffin hydrocarbons present in petroleum distillates is of great importance in forming aromatics in large yields.

(4) All paraffin hydrocarbons form aromatics but with varying percentage yields, on the basis of the oil used.

(5) The temperature at which the petroleum is cracked is of primary importance in giving maximum yields of benzene, toluene, xylene, naphthalene, and anthracene. The effect of pressure and the time factor are of less importance within limits than temperature, but the three factors, temperature, pressure, and time, are

intimately related, and a nice balance must be held to yield maximum percentages of aromatic hydrocarbons.

(6) A cracked oil is not so well adapted to aromatic or gasoline production as is a petroleum oil.

(7) Whatever cracking takes place to the lower boiling point hydrocarbons from a cracked oil may be attributed to a large extent to unchanged petroleum in the cracked oil and not to its aromatic constituents.

(8) There is a limit to the number of times which an oil can be re-cracked, because of the tendency to form aromatic compounds which decompose neither into gasoline nor members of the benzene series appreciably, but toward the ultimate products, hydrogen and carbon.

(9) The course of aromatic hydrocarbon formation from paraffin base petroleum distillates in all likelihood is as follows:—

High and low boiling point paraffin hydrocarbons.

↓
Low boiling point paraffin and unsaturated hydrocarbons.

↓
Naphthenes (alicyclic hydrocarbons, polymethylene).

↓
Aromatic hydrocarbons as

benzene ←————→ toluene ⇌ xylene

diphenyl naphthalene.

↓
diphenylbenzenes.

↓
triphenylene.

↓
carbon and hydrogen.

The manufacture of carburetted water gas is essentially an oil-cracking process, and the evidence so far available goes to show that a good quality benzene and toluene can be obtained by washing the gas from this process. In the early days of the war, this source was unjustly ignored, owing to the lack of a good test for the benzol content of a gas. The shortage of gas oil supplies has considerably handicapped this source in England, but it affords vast possibilities in America, the home of carburetted water gas plants.

Some tests made at the Birmingham Gas Works showed that, of the oil cracked in this process, 3.27% appeared as benzene and about 2% as toluene, and the products were not seriously contaminated with paraffin hydrocarbons.

Egloff (Met. and Chem. Eng., 1917), experiment, ing with a Lowe carburetted water gas plant, obtained per 1000 cub. ft. of gas, 0.07 gall. of benzene, 0.06 gall. of toluene, and 0.01 gall. of xylene. On this basis he estimates that the carburetted water gas manufactured in America, if washed, would yield annually 8,689,000 galls. of benzene, 7,448,000 galls. of toluene, and 1,241,300 galls. of xylene.

In conclusion, the author desires to thank the Birmingham Gas Committee for permission to submit this paper.

APPENDIX.

A device which the author has found very successful for testing the benzene and toluene, etc. contents of a gas is shown in the diagram (which is drawn to scale).

It is designed to scrub 100 cub. ft. of gas in 4 to 5 hours, as that is the minimum volume of gas which gives a reasonable quantity of crude benzol for analysis.

The washer works on the continuous counter-current principle and is very similar in action to a fractionating column. It is constructed from sheet tin.

Gas passes in at the bottom, A, and travels up through the washer, bubbling through the circular serrated lutes in each compartment, and finally passes out at X. Prepared oil flows from the constant head, H, through the control cock, C, into the top of the washer and gravitates from tray to tray, down the sealed pipes, P, P', etc., to the bottom of the washer, where it collects in the chamber, D, until the end of the test.

In the present form, the gas bubbles through a $\frac{1}{2}$ -inch seal in each compartment, and with an initial pressure of 5 to 6 inches of water, the washer will scrub 20 cub. ft. of gas per hour, leaving no appreciable quantity of washable products in the gas. After once starting, if the oil has been carefully filtered free from grit, the washer requires little or no attention until the end of the washing period, i.e., 4 to 5 hours for 100 cub. ft. of gas.

The manner of carrying out a test is as follows:—

The reservoir, R, which is to feed the constant head, H, is filled *via* M with prepared oil, after closing C, E, and K. A rubber bung is then tightly inserted in M. Taps, C and E, are then opened and oil allowed to flow into the washer. Each time the tube, T, becomes unsealed, a little gas displaces oil in R, and T is re-sealed; in this manner the control tap, C, remains under a constant head as long as any oil remains in R. Consequently a uniform flow of oil is secured. As soon as the compartments have each received their quota of oil, indicated by oil commencing to flow from the bottom one, at the "run off," O (left open for the purpose and afterwards closed), the control tap, C, is adjusted, to give the necessary oil feed—depending on the gas rate,

etc. The metered gas is then passed through the washer. At the end of a test, the main bulk of the oil having collected in D is run off and also that from each compartment by the drain holes, O, O', etc. (being uncorked for this purpose).

The crude benzol is then steam-distilled out of the oil in the usual manner and analysed by Colman's method.

About 4 litres of oil is required to scrub 100 cub. ft. of gas, and this, or more, is easily carried in the washer. The reservoirs, R and D, have capacities of 1 and $1\frac{1}{4}$ galls, respectively.

A test can be started and the figures for the pure benzene and toluene contents of the gas determined within 8 hours, i.e., 5 hours for washing and 3 hours for analysis. Chemists who have had to determine the benzol content of a gas will appreciate the advantage of the speed of the above method. A smaller initial gas pressure than 5–6 inches water can be used by employing a smaller number of compartments but the gas rate must then be lowered accordingly.

DISCUSSION.

Dr. J. C. CAIN said he had not been able to ascertain that the German claim to the discovery of benzene before Faraday had been substantiated. There was practically no difference between synthetic phenol and natural phenol. Mr. Rhead had suggested that benzene was fairly easy to purify and that it could be done by freezing. He should like to know how such a process was used. The reference to Rollason, Stevenson, and others was interesting, but he believed that the process had not proved successful.

Mr. W. J. A. BUTTERFIELD said that he had published figures 20 to 25 years ago showing that it was possible to obtain carburetted water gas so that the vapours in the gas consisted entirely of aromatic hydrocarbons.

Dr. R. LESSING asked what was the percentage of oil extracted from the gas, and what was the percentage of recovery by distillation.

Mr. F. H. ALCOCK recalled having heard it stated in a lecture many years ago that the discovery of benzene was made in this country, where it was found in the liquid which separated in the cylinders containing compressed gas which were in those days utilised for conveying the gas to the point of consumption.

Professor BONE suggested that the gas referred to by Mr. Alcock was oil gas and not coal gas.

Mr. RHEAD, in reply, said that the statement as to the German claim concerning the discovery of benzol was contained in Lunge's "Coal Tar and Ammonia" (Vol. 1, p. 224). Lunge (Vol. 2, p. 940) also stated that chemically pure benzene was made by a freezing process. As regarded synthetic phenol, he had been under the apparently wrong impression that it was easier to purify than coal-tar phenol owing to the cresol contents of the latter. He did not know to what extent recrystallisation was necessary for the T.N.T. prepared from paraffinic toluene.

In the early days of the war, there had been a doubt in some quarters concerning the paraffin content of the toluene obtained from the washing of carburetted water gas.

He had been unable to wash out any more crude benzol from the gas after the latter had passed through the washer described. By fairly prolonged steam distillation he had been able to recover all but a negligible quantity of the crude benzol from the oil. The amount of steam distillation necessary had been determined by steam distilling known mixtures of benzene, toluene, and wash oil.

RECENT DEVELOPMENTS IN THE INDUSTRIAL APPLICATION OF TOWN'S GAS.

BY C. M. WALTER, B.S.C.

The developments which have taken place during the past few years in the application of town's gas for industrial, heating, and manufacturing purposes have been such as to signify that the future of this form of fuel is largely dependent on its employment in this connection, and further to predict the possibility of very great developments in this application as a substitute for solid fuel.

The degree to which town's gas will ultimately replace solid fuel will naturally depend to a great extent on the increased heating efficiency to be obtained by its use, and when it is remembered that at the present time, in many instances, town's gas has been able to compete favourably with solid fuel, with but slight increase in heating efficiency, owing to the economies obtained by its use in other directions, it will easily be realised to what extent its field of application will be extended when the efficiency of the town's gas-heated furnace is still further increased as to reduce the cost of the B.Th.U. required to perform a given operation to a figure comparable with that obtained with solid fuel.

That the heating efficiency of the gas furnace will be considerably increased there is little doubt, as up to the present little has been done in the way of conserving the heat carried away in the waste gases by the employment of regenerative systems, in furnaces designed for operating with this fuel, and it seems possible that the heating efficiency might in some instances be so increased by this means, as to enable town's gas to compete with solid fuel on a fuel cost basis alone. To quote an example where this has actually been the case, the author can refer to an installation of gas-heated lehrs, which were installed some few years ago for the annealing of glass. The installation referred to consists of two annealing furnaces, each approximately 74 ft. in length and 5 ft. 6 in. in width by about 2 ft. 6 in. in height to centre of arch, the combustion chambers extending for a length of 20 ft., being arranged beneath the bed with suitable regenerative settings for the pre-heating of the air. Gas was supplied at ordinary town pressure through ordinary atmospheric burners, the secondary air being pre-heated prior to its entrance to the combustion chambers. The results of tests carried out on the furnaces referred to showed that to maintain a temperature of about 550° C. when under load, a gas consumption of approximately 750 cub. ft. per hour was required, corresponding with an efficiency of just over 30 %, whereas in the case of a similar furnace direct fired by coal, the fuel consumption approximated to 1 cwt. of coal per hour, corresponding with an efficiency of approximately 8.5 %; the fuel costs amounted to 11.25 pence per hour in the case of the gas-heated furnace, as compared with 10.8 pence per hour in the case of the coal-fired furnace, the cost of handling the fuel not being included in the latter case; thus owing to the increased efficiency with the former system of heating, the fuel cost alone was only slightly in excess of that obtaining in the case of solid fuel-fired furnace. This is referred to merely as an example of the increased efficiencies which can be obtained by the judicious application of town's gas, and although it may be said that the solid fuel-fired furnace has yet to be considerably improved, nevertheless, making due allowance for such improvements, the advantages obtained by the use of town's gas due to cleanliness, convenience, simplicity, and ease of temperature control

must weigh greatly in its favour, in the case of many manufacturing processes.

It is the intention of the author, in this paper, to refer to the more recent applications of town's gas as an industrial fuel in connection with metal melting, annealing, hardening, etc., rather than to deal at length with figures of fuel cost which obtain in its many applications, as compared with other forms of fuel.

Metal melting.

The developments which have taken place during the last twelve months in connection with the application of town's gas for metal melting, have been in some respects phenomenal, and at the present time many thousands of brass, gun-metal, and aluminium castings are being produced daily in melting furnaces heated by this fuel. At the same time large quantities of metal are being melted for the production of strip, billet, and ingot in gas-heated furnaces, with considerably increased economy in melting costs as compared with other forms of fuel. For the production and melting of aluminium alloys, gas-heated furnaces having pots of capacity up to 600 lb. (copper) are being employed, with the result that not only has the speed of melting been considerably increased, but the fuel cost has been reduced, and in many cases superior quality alloys have been produced owing to the cleanliness and ease of temperature control which obtain when melting under such conditions. In the case of the melting of brass, bronze, and gun-metal in gas-heated furnaces, the output has, in many instances, been considerably increased and at the same time the metal loss during melting reduced.

With regard to the relative efficiencies of direct-fired melting furnaces heated by coke and gas, figures obtained from a series of experiments carried out some time ago in connection with the melting of common yellow brass showed these to be in the ratio of approximately 3 to 15 respectively, again showing the large increase in heating efficiency which has been obtained with coal gas as a fuel.

Perhaps a more recent application of town gas in this connection is its use for the melting of cast iron. At the present time, in many parts of the country, cast iron is being melted in pots of 60 to 120 lb. capacity with town's gas, for the production of high grade castings, and although the fuel costs are considerably higher than when melting by coke, it is found that owing to the superior quality of work which can be obtained, this extra fuel cost is easily justified. The results of tests carried out in connection with this work show that about 700 cub. ft. of town's gas of calorific value 600 B.Th.U. gross is required for each cwt. of metal melted, and that from 7 to 9 heats of metal are obtainable for each pot.

Annealing.

For the annealing of iron, steel, and brass stampings, forging, etc., gas is rapidly replacing solid fuel, especially in cases where it is found advisable to split up the annealing plant into small units. In this connection the replacing of solid fuel-fired furnaces by modern gas-fired furnaces fitted up with suitable temperature indicating apparatus, has placed manufacturers in a position in which they are able to deal with work of a repetitive nature, in a very different manner to what they were accustomed to when working by rule-of-thumb methods.

Taking, e.g., the annealing of brass and steel stampings, an enormous industry of this city, one no longer sees in this connection the cumbersome coal-fired furnace: in its place we now have a number of small furnaces heated by gas at ordinary pressure, each constituting a complete

unit fitted with its temperature indicating apparatus and capable of dealing with work at a speed at least double that of its predecessor.

The advantages brought about by this change result in the work being done more expeditiously, with greater uniformity, and at a lower manufacturing cost, for temperatures can be quickly and easily controlled with absolute precision; the number of units in use can be adjusted in accordance with the amount of work to be dealt with, and the working of such a plant becomes, to a great extent, automatic.

The extent to which gas is replacing solid fuel in this particular application may be gathered from the fact that in this city alone, during a period of nine months, upwards of £12,000 worth of gas-heated furnaces have been installed on the premises of various manufacturers engaged on Government work, this representing an increased gas consumption amounting to upwards of 250 million cub. ft. per annum.

Carburising, hardening, and tempering and general heat treatment of metals.

What has been said with regard to annealing applies equally to such processes as carburising, hardening, and tempering and the general heat treatment of metals, in which processes town's gas is now being employed to a very considerable extent. Special furnaces for particular processes of heat treatment are being designed almost daily, with the result that working efficiencies are being considerably increased.

During the last six months, a considerable amount of investigational work has been carried out in the Industrial Research Laboratories of the City of Birmingham Gas Department, in connection with the carburising of mild steel in an atmosphere of coal gas, and already this process is being used with considerable success for the carburising of small parts of machine tools, gauges, etc.

New methods are also being employed for the heating of delicate tools for purposes of hardening, by radiation in an atmosphere of coal gas to avoid oxidation, and by combining this process with a special arrangement for heating by radiation, it has been found possible to reduce the amount of distortion which takes place on quenching to a minimum.

The applications of town's gas for industrial heating purposes have been so varied and numerous as to require a large amount of scientific investigation and experimental work to be carried out to ensure that the most economical methods for the carrying out of any particular process are employed, and with this object in view the Industrial Research Laboratories of the Birmingham Gas Department are working, hand in hand, with the various manufacturers, as only by this means does it appear possible to combine science with practice to bring about the results required.

When dealing with the question of industrial heating, no paper would be complete which did not make reference to the subject of pyrometry, a subject which is, at the present time, receiving considerably more attention than it has in the past. The employment of pyrometers in all heat treatment operations of a repetitive nature must receive still more attention by the manufacturers in the future, and every facility should be offered to ensure that the correct type of instrument is used for any particular process under consideration.

The many advantages obtained by the use of town's gas in the particular manufacturing processes referred to above also apply to a more or less degree to other manufacturing processes such as glass manufacture, porcelain firing, japanning, lacquering, etc., in consequence of which the gas-heated furnace is gradually becoming a

sine qua non in the industries referred to, and speaking generally it may be said that application of gas as an industrial fuel has gone far to augment the output of munitions and war stores of the large manufacturing centres of our country.

In conclusion, the author wishes to offer his thanks to the Birmingham Gas Committee for their permission to contribute this paper.

DISCUSSION.

The PRESIDENT said that Mr. Walter's statement as regarded the work done by the Birmingham Gas Department was most interesting. To achieve success they had spent a considerable sum of money and installed important plant.

Mr. DRUMMOND PATON asked as to the pressure at which air was introduced into the furnace.

Mr. TAUDEVIN agreed with the author that the development and the design of gas furnaces was in a crude stage. He did not think he had seen a really well-designed annealing gas furnace yet, though he had seen gas furnaces which gave promise of good results.

Mr. E. W. SMITH stated that in the south of England Sir Alex. Duckham had 16 muffles working successfully. They were 15 feet by 5 feet 6 inches, all raised above the ground and heated with producer gas, and they were so arranged that the bottom of the furnace could be dropped out. The strip for annealing was placed edgewise on the bottom and the furnace was rarely opened for more than forty seconds, and in two hours it was possible to treat 3 tons, corresponding to 30 or 35 tons of metal through-put per day. It was not possible to determine with the pyrometer a difference of more than 5 to 10 degrees of temperature in any part of the muffle. The heating was uniform and very easily controlled. He thought the gas companies would have to face the competition of producer gas in muffles. Water gas was not nearly so suitable for many methods of heating. The dilution of producer gas enabled one to get more effective flame over moderate temperatures and over big areas.

Mr. A. E. TUCKER submitted that the pressure should be exercised on the gas and not on the air. It was invariably the case in the furnaces with which he was connected and that detail was of great importance, because by that means alone the action on the pots could be much reduced, and pots at the present time cost £1 or £5 each. Secondly, the control of the heat was much more easily effected. The limits of copper in brass were specified by the Ministry of Munitions as between 57 and 62%, and it was a wide margin, but labourers did not always appreciate the significance of using excessive heat, and the result was that in some gas-fired furnaces, he had known a loss of 10% of zinc; a considerable amount of brass had thus been wasted.

Mr. H. L. HEATHCOTE said that one Coventry firm paid over £3000 a year for gas for industrial purposes. He was glad that Mr. Walter had emphasised the need for pyrometric control in connection with furnace work. To a very large extent the value of the furnace was determined by the accuracy with which its working could be controlled.

The PRESIDENT said he thought a mistake often made was in depending upon the average workman to use a pyrometer having a scale which was not sufficiently open. He had reason to know that where a pyrometer with an open scale had been used, not much difficulty was experienced in getting working men to work within close limits.

Mr. WALTER, in reply, said that in their furnaces air was used at a pressure of about 2 lb., with gas at the ordinary town pressure. In many cases it was found to be more satisfactory to use both gas and air under pressure. The main advantage

to be derived from using the combined arrangement was that the variations which were bound to take place were eliminated when one was dealing with gas at some positive controlled pressure. In Birmingham they had upwards of 17 miles of high-pressure mains, which transmitted gas at a working pressure of 12 lb. per square inch, and in cases where manufacturers were on the route of these mains the Corporation were in the position to supply them with melting furnaces in which the gas was supplied under pressure and the air taken in by injection in the ordinary way. A considerable number of these furnaces had been in operation for some 5 or 6 years. Where there was a difficulty of obtaining high-pressure gas it had been found to be a commercial proposition to instal compressing plant. He agreed as to the ease of control and efficiency of the high pressure gas-heated furnace. When high-pressure gas was employed direct, the amount of gas it was possible to introduce into the furnace was decided by the size of the jet and the working pressure. To some extent that prevented the possibility of the metal being over-heated by using an excess of gas just prior to pouring.

THURSDAY AFTERNOON.

GROUP I.

The PRESIDENT in the Chair.

MANUFACTURE OF SYNTHETIC NITRATES BY ELECTRIC POWER.

BY E. KILBURN SCOTT, A.M.INST.C.E., M.INST.E.E.

PART I.

In the process of fixing atmospheric nitrogen in an electric furnace, the reaction mainly depends on the contact of air with the electric arc. Clearly therefore that design is best which provides for most air to come under the action of the arc.

Many furnaces are faulty because a large proportion of the air passing through cannot come into contact with the arc, and on the reason being investigated it is found to be due to their being of the single-phase type.

For example in the Birkeland-Eyde furnace (see this Journal, 1915, 114) the arc alternately fills the top and bottom half, but never both simultaneously, and as air flows into the reaction chamber through all the holes, it follows that only half of it can be on the side where the arc is, at any moment. There is thus a leakage of air and it is especially pronounced through the holes nearest the periphery.

In the Schönherr furnace (this J., 1915, 115) a rod-like arc is formed up the centre, and a whirling current of air keeps the arc in the centre. As the section of the arc is only a fraction of an inch, whereas the cross sectional area of the tube is over 30 square inches, much of the air passes without contact. This is helped by the whirling action which tends to keep air away from the arc.

The Pauling furnace (this J., 1915, 116) consists of horn-shaped electrodes between which a fan-shaped flame is formed by the single-phase current which shuttles backwards and forwards between them. The nozzle of the air pipe is provided with a narrow slit, but as air cannot travel in a flat stream, it spreads in all directions. Therefore a large portion of the air must necessarily pass through the furnace without coming in contact with the arc.

Further particulars of the above furnaces are given in my paper on "Production of Nitrates from Air" in Journal for February 15th, 1915, No. 3, Vol. XXXIV.

Another single-phase furnace not described therein, is that of Mosciicki which is used in Switzerland. This type (see Fig. 1) has a reaction chamber, A, and air chamber, B, surrounded by

water. An annular space is provided between the high-tension electrode, C, and the lower edge of the reaction chamber, which latter is at earth potential. The arc strikes across this annular space and it is caused to rotate by the magnetic field set up by coil, D.

Naturally the single-phase arc can only be at one point of the annular ring at any one moment, whereas the air passes through all the ring space, all the time. Therefore this design, which otherwise has several good features, presents the disadvantage common to all single-phase furnaces of allowing air to pass through without contact with the arc.

FIG. 1.
Mosciicki single-phase furnace.

Three-phase furnace. Now consider what happens in the three-phase furnace shown diagrammatically in Fig. 2. The three electrodes, A, A', A'', are arranged with intervening firebricks, B, B', B'', so that together they entirely enclose a six-sided conical space. Air entering the bottom from the pipe, C, expands and fills the cone before passing away at the top, the only exit.

The electrodes receive the three-phase currents, a, a', a'', and these currents interact in such way as to produce an arc flame which rotates rapidly in accordance with the periodicity of the supply, viz., 50 times a second.

Since the air takes longer than 1/50th of a second to pass up through the reaction chamber, every particle must come into contact with the rapidly revolving triple arc flame.

It is rather surprising that those who are interested in nitrogen fixation abroad should have only worked on single-phase lines. Having started

in that way they still keep to it owing no doubt to patent considerations, and the absence of competitive conditions.

When alternators first came into use all alternating current plant was single-phase, but directly three-phase motors came into vogue then single-phase began to go out. For a certain period two-phase apparatus was employed because it was easy to change over to it from single phase. Three-phase generators are now universally used, and yet for fixation of nitrogen, the Kilburn Scott type is the only one designed as a self-contained three-phase unit.

Fig. 2.

Diagram of Kilburn Scott furnace, showing entirely enclosed and conical reaction chamber, in which the combined three-phase arc flame rapidly rotates.

By employing three currents in one reaction chamber, the electrical energy is converted into heat at an even rate, because power varies between 0.86 and unity, taking the maximum as unity. This is indicated by the three alternating curves shown in Fig. 2, the crossing points of which are only a little below the maximum values. On the other hand the single-phase curve clearly indicates that in a single-phase furnace the power varies between zero and a maximum twice every cycle or period.

Blown arc flames. For the proper working of nitrogen fixation furnaces, it is essential to blow the arcs into flames, and this can be done by a magnetic field as in the Birkeland-Eyde furnace, which causes the arc flame alternately to expand into two half discs. Mosicki's furnace has a magnetic field which causes the arc to rotate round an annular opening, but the arc is extended

into a flame by the air which blows through the opening.

On the other hand furnaces can work merely by the air flowing through as in the Schönherr, Pauling, and Kilburn Scott types.

One objection to the magnetic blow is that in addition to alternating current for the arc, direct current is also required to excite the magnets. To obtain the direct current, special transforming plant is necessary, and it must be of the rotating type because of commutation. The first cost and upkeep are therefore high.

Seeing that, in any event, air must pass through the furnace, it may just as well be used for creating the flames, and thus do away with extra direct current plant. The arc flames obtained by air are just as effective as when obtained by magnetism.

In the Schönherr furnace the air is given a whirling motion to keep the arc in the centre of the tubular reaction chamber, but in the Pauling and Kilburn Scott furnaces this is not necessary.

Electrodes. For a given power or output the trouble of operating electric furnaces may be said to vary with the number of electrodes. Also the energy lost in electrodes will vary with their number. The least that can be used for any furnace are two and, therefore, three furnaces of single-phase require six electrodes, as shown in Figs. 3, 4, and 5. On the other hand, a three-phase furnace requires only three electrodes as shown in Fig. 6.

The Birkeland-Eyde furnaces, Fig. 3, are shown in "delta" connection, this being the preferred method, but some of those in Norway are also connected in "star." Schönherr furnaces, Fig. 4, are always connected in star, and as the top electrode of each furnace is earthed, there are only three electrodes at high tension.

Pauling furnaces are worked two in series, and they have a special transforming device, as shown in Fig. 5, which raises the voltage temporarily, in case one furnace of the series goes out. This assists towards continuity of working.

The material of which electrodes are made has an important bearing on the yield. For example the electrodes of the Birkeland-Eyde furnace are a special alloy of copper which has been found from experience to be beneficial.

The modified Pauling furnaces which Dr. Rossi has at work in Legnano have electrodes made of an aluminium alloy, and he claims that the metal has a catalytic action which is favourable to the yield. (See Brit. Pat. 23,959 of 1913.)

Schönherr and Mosicki furnaces, which have one of the electrodes at earth potential, must of necessity use iron or steel for one if not both electrodes. The iron oxide carried over with the gases is detrimental.

In my three-phase furnace a special alloy is used, particulars of which it is not desirable to disclose.

Starting furnace. Single-phase furnaces are started by moving the electrodes towards each other until the air gap is sufficiently narrow for the voltage to jump across. These adjustments have to be carefully made, as the electrodes are at high tension, and there is also liability of current rushes.

In the three-phase furnace, I dispense with adjustments because the arcs are started by pilot or trigger sparks. A wire placed about midway between the points of the three electrodes, just above the air pipe, is connected to a high-frequency apparatus. When this apparatus is started sparks pass from the wire to the electrodes, and thus break down the air dielectric. The operation of starting the furnace is first to turn on the air, then close the main three-phase switch, and finally switch on the pilot sparks.

By employing high frequency, many pilot sparks pass during each cycle of the main supply, which latter is 50 cycles per second. A continuous path is therefore provided for the main current. The

apparatus for attaining this and the method of connecting up are special and have only been arrived at after considerable experimenting. It will be seen, however, that two currents at different frequencies can work through the same conductor or it is practically the condition which enables telephone and telegraphic messages to pass together.

This method of starting is a great advantage because the electrodes can be set at the best distance apart for the air supply, and a low pressure can be used to operate the furnace. Without the pilot sparks the voltage has to rise to a certain point before current begins to flow and this affects the power factor.

FIG. 3.

Three Birkeland-Eyde single-phase furnaces, connected in delta with 6 electrodes, all adjustable and at high pressure. A separate disc arc flame in each furnace.

It is convenient to keep the pilot sparks working all the time because it improves the yield and helps maintain continuity of working. In all electric furnaces it is most important to ensure continuity, because if the furnaces keep stopping and starting, surges may be set up. A three-phase furnace has a special advantage in this respect because currents are always flowing in the phases and the arcs assist in maintaining each other. The energy is practically always at a maximum, whereas in a single-phase furnace it varies from zero to a maximum twice in each period or alternation of the current.

Preheating. In order to get easy operation of the furnace the air must be preheated, and so long as such preheat is not detrimental in other ways, the higher it is, the better. Ionisation is helped by preheat and this condition is necessary for good electrical working. I have found it advantageous to preheat to 250° C.

It is convenient to get the preheat from the heat of gases leaving the furnace and one large heat exchanger can serve several furnaces.

The Birkeland-Eyde design embodies a preheater because the cold air blown into the furnace goes first into two chambers behind the perforated walls, and in passing through the numerous small holes to the reaction chamber it receives preheat.

In the Schönherr design the preheater is more apparent because it takes the form of several concentric steel tubes outside the reaction tube. It is an effective preheater, but the combination of a preheater with each furnace is costly. In one furnace room at Saaheim factory in Norway, there are 96 preheaters, whereas several separate heat

exchangers could preheat all the air required in a more effectual way.

Preheating the air not only economises heat, and raises the temperature of the furnace but it also enables the air to enter the furnace dry, which is an advantage. Prof. Guye found a slight increase in yield when the air was dry, enough to warrant the removal of moisture in a commercial plant.

I think it may be taken as an established fact that if air is used without any previous treatment, the yield of a furnace will differ with varying atmospheric conditions. Air charged with moisture or with dust or with acid vapours as found in some industrial centres will not act in the same way as the clean dry air of, say, an inland

FIG. 4.

Three Schönherr-Hessberger single-phase furnaces, connected in star with 6 electrodes, 3 of which are adjustable and at high pressure. A separate rod-like arc in each furnace.

mountainous region. Natural electrical phenomena are much manifested in a pure dry atmosphere.

Cooling. As the chemical reaction is reversible, it is important to chill the nitric oxide quickly. With single-phase furnaces, it can only be effected by blowing excess air through the furnace, whereas in the Kilburn Scott furnace a cooling device in the form of a boiler acts as the roof. Boilers would no doubt have been applied directly to the single-phase furnaces in Norway, if the designs had been suitable.

It will be noted from Fig. 1 that a boiler is an essential part of the Moscicki furnace, and in that respect I consider it is an advance on the other single-phase furnaces. But considered as a boiler it is faulty, and the reason is simply that it has had to be made to suit the special requirements of the reaction chamber, etc. By employing a boiler simply as the roof of the three-phase furnace it becomes a straightforward job and there is no compromising of either the reaction chamber or the boiler.

Cooling by means of a boiler is effective by reason of the latent heat of steam and there is also considerable economy because the steam can be used for generating electric power. There is a regenerative gain of over 10% by passing the steam into a mixed pressure steam turbine. If not wanted for that purpose the boiler can produce distilled water for the absorption plant.

A blown arc flame acts on the boiler in much the same way as any ordinary flame burning to carbon dioxide. The centre of the arc flame

is the neutral point, and as I connect the boiler to earth, there is no danger and no electrical leakage.

The boiler is not affected, because nitric oxide does not attack metal. Nitrogen peroxide may do so if the temperature is below 600° C., but even it acts slowly and moisture must be present.

In Norway the furnace gases are passed through an ordinary Babcock-Wilcox boiler when the temperature has been lowered to about 200° C., so the gases are at a temperature which is dangerous. From the point of view of action on metal it is much safer to use the boiler *directly* on the furnace where the gas is still in the nitric oxide stage.

Results. The yield which it is generally assumed can be obtained from single-phase furnaces is 50 to 60 grms. of pure nitric acid per kilowatt-hour, or, say, half a ton of pure acid per kilowatt-year. Tests carried out on my three-phase furnace show greater yields, and I consider 50% higher than the above is commercially feasible.

The yields are much improved by having a boiler immediately over the arc flames, and there is no appreciable difference in yield when steam

Those specially interested are referred to Fig. 9 of my paper on "Production of Nitrates from Air" in Journal for February 15th, 1915, No. 3, Vol. XXXIV. This shows a lay-out of absorption towers, etc., and also my proposal to supply the furnace with oxygenated air and work in a closed cycle by bringing air from the last tower back to the furnace.

Dilute nitric acid is collected at the bottom of each tower and forced up to the top of the next. The liquor passes from tower to tower in one direction whilst gas passes from tower to tower in the other direction. Such a system gives an acid concentration of about 25%, which is high enough for making ammonium nitrate and calcium nitrate.

It happens that during the absorption process nitrous acid is formed, and this, being unstable in presence of water vapour, splits up into nitric oxide and nitrogen peroxide. The nitric oxide then takes up more oxygen from the excess air present, and for this it is well to make provision by allowing the gas to move sluggishly between the towers.

It will be of interest to consider what are the conditions for good absorption. A first condition is that the gases move very slowly, and the next

FIG. 5.

Pauling single-phase furnaces, connected in two series and in "delta," with 12 electrodes, all adjustable and at high pressure. A separate fan-shaped arc flame in each furnace.

is being raised as there is before the water boils. Tests have shown that of the total energy put into the furnace, the low pressure steam raised represents about 10%.

If the air is preheated to 250° C. then the yield rises to its full value in about $\frac{1}{4}$ hour from the time of starting the furnace, which is important from the point of view of switching off the furnace during off-peak hours.

The pressure at which the furnace will work is considerably lower than the voltages used in single-phase furnaces. Power factors of over 0.85 have been obtained.

Absorption towers. The most commonly used absorption system consists of a range of high towers made of acid-proof brickwork, the towers being filled with quartz pieces or one of the many patented forms of acid-proof filling. Gas enters the bottom of each tower and leaves at the top after finding its way through the interstices of the filling. At the same time the absorbing liquid covers the filling with a thin layer of liquid, which absorbs the ascending gas. The bulk of the absorption takes place in the first tower which receives the strongest gas.

FIG. 6.

Kilburn-Scoll three-phase furnace, connected della-star with 3 electrodes, at high tension. A rapidly rotating arc flame is produced by the three phases in the conical reaction chamber.

is that the contact surface should be as large as possible; also, as mentioned above, there should be opportunity for the further oxidation of the nitric oxide which is formed during absorption.

Prof. Moscicki has also found that it is desirable for the liquor to pass down the towers intermittently so that the filling is periodically wetted. His system is shown in Fig. 7, taken from Brit. Pat. 17,355 of 1911.

The absorption chambers are rectangular in plan, and built together in one block of acid-proof bricks, the party walls, A, pierced with small holes, B. Every second chamber, C, C, is filled with quartz pebbles to offer a large absorption surface. The other chambers act as oxidising chambers, and have an open kind of packing or else are empty. The width of each chamber is about the same as the height and it is only 15 to 30 cm. in the direction of travel of the gas. The space occupied by the whole apparatus is small as compared with the old system of separate towers.

The gas is caused to flow at the very slow speed of about 4 cm. per second, and it travels in a horizontal direction, through the holes in the party walls from chamber to chamber. The absorbing

liquid. D, is poured quickly and periodically over the layers of filling material so as to form each time a column of water which as it sinks downwards places all parts of the filling successively under water and thus thoroughly washes them.

Viewed from the gas inlet pipe the receiving vessels are arranged in stages rising towards the rear end of the chamber and each vessel is connected with the adjacent lower vessel by means of overflow pipes as shown. As distilled water is admitted at the rear end where gas is weakest it causes overflow towards the end where the gas enters and where acid is drawn off. The operation is automatic.

The holes through which the gas passes slope down towards the filling so to as prevent liquid getting through the holes into the oxidation chambers. The outer walls of the chambers are made tight to liquid and gas by a coating of acid-proof asphalt.

After the liquid has fallen to the bottom of each tower it is transferred to the top of the next by a *montejus*, the liquid moving in the opposite direction to the gas as in the other systems. By the Moscicki method the absorption of the nitric

FIG. 7.

Moscicki plant for absorption of nitric acid.

peroxide gas is nearly complete, being about 97%, whilst the nitric acid may be drawn off at a concentration of 40 to 50%.

PART II.

COMPARISON OF METHODS.

During recent years a great deal has been heard of the indirect method of making nitric acid; that is so say, by the manufacture of calcium carbide and calcium cyanamide, and the oxidation of ammonia. Those interested in this method have made comparisons between it and the direct electric arc process, with the object of showing that the indirect is the best. It will therefore be of interest to make out a complete statement of all the various items of the two methods, for obviously, that is the only way by which a fair comparison can be made.

INDIRECT METHOD.

Number of factories. Three, viz., one for calcium carbide, one for calcium cyanamide, and one for the acid.

Number of processes. Ten. (A) Burning limestone; (B) making calcium carbide; (C) grinding carbide; (D) making pure nitrogen; (E) making calcium cyanamide; (F) grinding cyanamide; (G) raising superheated steam; (H) making ammonia; (I) oxidation of ammonia by catalyst; (J) absorption of gas to nitric acid.

Materials. Seven. (A) Limestone; (B) coke or anthracite; (C) carbon electrodes; (D) pure

nitrogen; (E) superheated steam; (F) air; (G) water.

Purity of materials. It is very important (A) to have pure nitrogen for the cyanamide, (B) to free the cyanamide from all traces of carbide; (C) to have pure ammonia and pure air, because the catalyst is easily poisoned.

Electric energy. Electricity is required: (A) For calcium carbide furnace; (B) for calcium cyanamide retorts; (C) for heating catalyst; (D) for powerful motors for grinding the carbide and the cyanamide and for moving these materials.

Grinding machinery. Special machinery is required for grinding the calcium carbide very finely in an atmosphere of nitrogen, so as to prevent formation of acetylene, also for grinding calcium cyanamide.

Steam. Superheated steam is required for making ammonia from the cyanamide in autoclaves. The steam is raised by burning fuel.

Catalyst. Platinum is used as a catalyst, and as it is consumed it has to be renewed.

Electrodes. Amorphous carbon electrodes are required for the carbide furnaces, and the cyanamide retorts. They burn away quickly, and are expensive.

Method of working. A calcium carbide furnace must work continuously, because if the fused material solidifies, it may spoil the furnace lining. The calcium cyanamide retorts must be worked intermittently.

Situation of factory. The site must not only be where electric power is available, but also where limestone, coke or anthracite, and carbon electrodes can be conveniently and cheaply delivered.

Labour. A great deal of labour, much of it skilled, is required to attend to the ten processes, and the large amount of special plant required. The intermittent method of making cyanamide in numerous small retorts requires much hand labour.

DIRECT METHOD.

Number of factories. One.

Number of processes. Two. Nitric oxide gas, made by passing air through an electric arc flame. The gas is then combined with water to form nitric acid.

Materials. Two. Air and water.

Purity. Nitrogen and oxygen are used exactly as they exist in the atmosphere. No precautions necessary.

Electric energy. Energy is only required for the furnaces and sundry small motors.

Grinding. None required.

Steam. Raised by the waste heat of furnace gases.

Catalyst. None.

Electrodes. Water-cooled metal, which wear away very slowly.

Method of working. It is best to work continuously, but the process lends itself perfectly for intermittent working, so as to take advantage of low off-peak or off-season rates.

Situation of factory. The site may be anywhere where suitable electric energy is available. It is not affected by carriage of raw material.

Labour. Very little required, as there is only one process, and that is practically automatic.

It has often been stated that the amount of electric energy required for a given amount of nitric acid made by the *indirect* process, is less than that required by the *direct* process. I have yet to see reliable figures proving this, but even if it were true, it is only one item. The only way to compare two methods is to take into account all the factors, and appraise them at their proper value.

To show how absurd is the argument, one may as well say that the electric energy (represented

by a few motors and lights), required for a plant making acid from sodium nitrate, is much less than by all other processes. That does not prove anything, and yet it is no more absurd than the other argument.

On the question of first cost of plant, the *indirect* method is not in the running at all. For assume for the sake of argument that the cost of a carbide furnace and its accessories is about the same as that of an air nitrate furnace and its accessories, and that the absorption plant required by the two processes is also about the same.

Then, in addition, the *indirect* process requires:—

- (A) A complete plant for making cyanamide.
- (B) Liquid air plant for making pure nitrogen.
- (C) Powerful machinery for grinding the carbide and the cyanamide.
- (D) Steam boiler, and autoclaves for making ammonia.
- (E) A complete catalytic plant for oxidising the ammonia to nitric acid.

Plant is also required for purifying the materials and gases, etc. At the cyanamide works at Odda in Norway they have actually had to carry a pipe up the mountain side so as to get pure air, that about the factory having given trouble with the liquid air plant.

As regards the cost of materials the *direct* method is at a tremendous advantage because the cost of one material is zero and will always remain so, and the other—water—is cheap and not likely to increase. On the other hand, the materials required for the *indirect* method are very expensive and especially difficult to obtain at the present time.

Over three-fourths of the cost of working the *indirect* method is represented by cost of materials which are liable to fluctuate in price, and are now much higher than before the war and will remain up. On the other hand in the cost of working the *direct* method, less than one-fifth represents cost of materials which depend on market rates. The principal item of cost, namely, electric power, will most certainly tend downwards.

The *direct* method is automatic in its working, whilst the *indirect* method requires much skilled and unskilled labour, and some of the operations are dangerous to health. The more that labour demands increase, the more is the *indirect* method handicapped.

Power. It is often said that there is not enough electric power for electro-chemical processes, and we cannot generate power cheaply enough. As a matter of fact, for some years before the war electric energy had been sold in this country at lower rates than those at Niagara.

In the future the problem of cheap electric power is going to be solved for this country by the establishment of super-power houses, and some of 120,000 kilowatts each are already projected. Generation of energy by coke-oven gas will also give a large amount of power, and as time goes on, the manufacture of coke will be carried on on a much larger scale and all bee-hive coke ovens be replaced by up-to-date ovens, recovering the products, and giving large amounts of gas. It is estimated that the gas from a battery of 100 modern coke ovens will generate 3000 or 4000 horse power.

Electric power generated by super-power houses, and by utilisation of waste gas, will be used for electro-chemical and metallurgical processes, and I am confident that the manufacture of nitrates from air by the *direct* method will be one of the principal of these.

The *direct* process lends itself particularly well because it is so suitable for off-peak or off-season loads. The furnaces differ from most others in that there is no fused material to solidify, and very little brickwork to deteriorate in case of a stoppage. The furnace can be switched on

and off like an arc lamp without detriment to the furnace or to the process of manufacture.

As a basis load for a power house the *direct* process also presents the advantage that it can be established anywhere. The only raw materials are air and water, and therefore considerations of carriage do not weigh, as is the case with many other electrical products. The factory can be built alongside the power house.

In the case of power from coke ovens the *direct* process presents the advantage that the electric power can be used to make nitric acid, which is then combined with ammonia in the gases to produce nitrate of ammonia. This is better than purchasing sulphuric acid, and the nitrate of ammonia has the advantage over sulphate of ammonia in entering a better market and commanding a higher price per unit of combined nitrogen.

One very important fact regarding the manufacture of chemical products is that they are sold on analysis, and so long as prices are right the products will command a market.

The market of nitrogen compounds does not depend on goodwill, advertising, and so on, like that of manufactured articles.

Conclusion. I would like to point out that before the war the Central Powers were the largest purchasers of Chili nitrate, Germany taking twice as much as the next consumer, the United States, and over six times as much as this country. Now they do not require any, because they have established immense plants to make nitrates from air, and by keeping money in the country they are at an economic advantage.

The manufacture of nitric acid from Chili nitrate, which is universal in this country, is not only wasteful and expensive, but the raw material has to be transported 5000 miles in expensive tonnage at considerable national risk. Hitherto the powerful financial and other interests concerned with Chili nitrate have had their own way. It is now of national importance that reactionary influences should be stopped and steps taken to bring this country into line with other countries in the adoption of modern scientific methods of making nitrates from air.

DISCUSSION.

Mr. BOWER said that he had been much impressed with the description of the absorption process of Mosicki, which seemed a very good method, because in the treatment of these gases it was necessary to carry out a double function, to oxidise and to absorb. The cycle of operations was so speedy that it was almost simultaneous, although in practice the time for oxidation might or might not be longer than the time for absorption.

The PRESIDENT pointed out that the matter had not been neglected by the authorities, and that a good deal of work was being done at the present time with regard to this all-important matter. The outstanding difficulty, when entering on the erection of plant of this magnitude, was to decide whether to adopt a process which required the minimum amount of power or a process such as Mr. Scott had described in which it was suggested that the power requirements were considerably larger. Though the *indirect* process might require very much less electrical energy, in the long run it might be found that the *direct* process was better than the *indirect* one, although more had to be paid for electrical energy.

Dr. M. E. FYLEMAN asked whether there was any possibility of electrolytic corrosion in the boiler; any sort of electric current in and around a boiler used for steam raising was apt to be inconvenient and sometimes dangerous. From what one gathered in a general way it was almost if not entirely impossible, under practical conditions, to convert completely the nitric oxide

obtained in these processes into nitrous or nitric acid, the loss of nitrogen amounting to some 3 or 5% according to the literature. He would like to have some figures indicating roughly the cost of plant necessary to produce a certain quantity of nitric acid and to hear something about the cost of labour and supervision. This information would make it very much easier to form an idea of the possibility of using the process described.

Mr. F. SPROXTON said that it was somewhat puzzling to hear that the yield with Mr. Scott's new furnace was only 50% better than with the old furnace. It seemed that the advantages Mr. Scott claimed should have led to a far greater yield than that. Would there be any advantage in modifying the composition of the air by admixture of oxygen so as to get nearer to the theoretical composition which would give the most favourable results?

Mr. WEBB said that as Mr. Scott had pointed out, the time factor in the whole process was the oxidation of the NO to NO₂, and this seemed to depend on the actual time of the traverse of the NO through the absorption towers. Previously the absorption had been spoiled to a very large extent by the use of very fine packing, such as broken quartz. It became obvious that there must be a packing in the towers which would give a sufficient surface and also ample free space. He was rather at a loss to see how Mosiecki's patent would improve matters to any large extent. Broken quartz packing gave approximately 40% free space. He did not see why there should be the two separate chambers. Why not have one chamber and, for example, ring packing? This gave approximately 75 or 80% free space, and at the same time a considerably greater surface than would be obtained with broken quartz packing, unless the broken quartz was of the order of a quarter of an inch or less, in which case he imagined the draught difficulties would be fairly considerable. Assuming that there was the correct amount of free space and surface, and that the NO was given time to oxidise, there were other factors such as the dilution of the NO with air when entering the towers, and this dilution depended to a very large extent on the factor of packing. He rather understood that the packing question had actually been solved by the Norwegian and Swedish workers.

Dr. R. H. PICKARD said he should like to hear an incisive discussion on the relative values of the two catalytic processes on the same lines as Mr. Scott had given the relative values of the cyanamide and the arc processes.

Mr. MASON mentioned the Rankin process, of which Prof. Norton had spoken most favourably.

Mr. SCOTT, in reply, said that Mr. Bower had made some useful experiments with reference to the absorption question, and therefore what he had said on the subject carried considerable weight. Dr. Carpenter had mentioned that the Government were doing something at last, but we were three years late. The late Minister of Munitions, Dr. Addison, had stated in a recent speech, that at last we were going to do something in the fixation of atmospheric nitrogen. With regard to the point raised by Dr. Fyfe, it should be noted that the boiler was carefully earthed; it was known that corrosion occurred under certain conditions when alternating currents passed through earth, but this was only due to the presence of certain salts in the earth. He did not think there was any danger, but the point was worth looking into. There was some escape of nitric oxide into the atmosphere with the systems used abroad. He had mentioned in a paper some years ago an idea he had of making a complete cycle, taking the air as it left the apparatus and bringing it back, adding oxygen to it on the way, so that instead of passing the air

alone, air plus oxygen would be used: he had found the yield increased very considerably by oxygenating the air. With reference to Mr. Webb's remarks about packing, he could only say that the Mosiecki method had undoubtedly given 50%. Quartz pebbles, quite small, were used; the small spaces were completely flooded with water, which sank gradually, and this was followed up again with another lot of water, completely flooding all the spaces. He did not believe a great deal in ring filling. It appeared that the Norwegians always used quartz. Time must be given for the oxidation of NO to NO₂ to take place in between the layers in the towers. He did not know the cost of the cyanamide process. The cost of the plant for the arc process was roughly about £8 per kilowatt. According to quotations given about two years ago a German firm was prepared to build a factory in this country for £6 10s. per kilowatt, but he thought £8 was a safe figure, although, perhaps, it would be a little higher now.

THE SYNTHESIS OF AMMONIA AND THE OXIDATION OF AMMONIA TO NITRIC ACID.

BY EDWARD B. MAXTED, PH.D., B.SC.

The direct production of ammonia from its elements is at the present time a subject of peculiar interest, not only by reason of the conditions under which the reaction is carried out in practice, but also because it constitutes the most economical method available, if the initial difficulties are once overcome, of fixing atmospheric nitrogen.

It has long been known that on leading a mixture of nitrogen and hydrogen over certain catalysts, such for instance as iron or manganese, small traces of ammonia are produced even at atmospheric pressure, while in conformity with the well-known principle of Le Chatelier, the equilibrium ammonia content for a given temperature is increased by carrying out the reaction at an elevated pressure, the use of a pressure furnace for the synthesis of ammonia having been described for instance by Jost early in 1908.

We are, however, almost exclusively indebted to the pioneer work of Haber for the discovery of catalysts which become active at comparatively low temperatures and therefore under conditions such that the ammonia content of the reaction mixture is raised to values sufficiently high to render possible the commercial utilisation of the synthesis, while the subsequent development of his methods by the Badische Anilin und Soda Fabrik constitutes a most remarkable example of the introduction of modern physico-chemical methods into commercial life.

Despite the fact that no less than about one million tons of synthetic ammonium sulphate per annum is being manufactured by the Badische Anilin und Soda Fabrik in Oppau near Ludwigshafen, the published information regarding the process is extremely scanty. For this reason it may perhaps be of interest to give some description of the work undertaken and results obtained by my own Company towards the establishment of a technically sound foundation for a synthetic ammonia industry in Great Britain.

The first step in the industrial synthesis consists in the choice and adoption of suitable methods for the manufacture of nitrogen and hydrogen. The formation of ammonia is extremely sensitive to the presence of even minute traces of inhibitive substances, and it is therefore absolutely essential for the success of the reaction that these component gases be obtained not only as economically as possible but also in a state of practically absolute purity and above all free from catalyst poisons of every nature. While methods exist for the direct production of a nitrogen-hydrogen mixture, these

in general tend to give a gas containing an appreciable quantity of catalytically poisonous carbon monoxide, and for this reason we find that it is not only simpler but also more satisfactory from an economic standpoint to manufacture our gases separately and to mix them in the proper proportions as and when required.

The most economical method for the manufacture of pure nitrogen is undoubtedly that of low temperature separation from air. We utilise for this purpose the Pictet process, according to which air, cooled by exchange and by other means down to, but not below, its liquefying point, is injected, in the gaseous condition and at a pressure approximately equal to atmospheric, into a separating column (see Fig. 1) over the plates of which a descending current of liquid nitrogen is allowed to flow. This liquid nitrogen exerts an analysing influence on the air to be separated, in that it permits the passage upwards, as a gas, of the nitrogen of the air, while atmospheric oxygen is condensed by the current of liquid nitrogen and flows as a liquid nitrogen-oxygen mixture into the lower part of the column, where it undergoes continuous fractionation in such a way that it reaches the reservoir at the bottom of the separating column as liquid oxygen practically free from nitrogen. It will thus be seen that, in the process which we employ, only one-fifth of the air to be separated is liquefied, the nitrogen being kept in a gaseous condition during the separation and only a small fraction being subsequently liquefied in order to maintain the flow of liquid nitrogen, necessary for separation, over the plates of the column.

This subsequent liquefaction of a small proportion of the nitrogen produced is carried out in two ways, namely, in the first place by slight compression in closed coils contained in the oxygen reservoir and on the plates of the column, a suitable pressure for liquefaction being obtained by the use of a small compressing system, of such a nature that the pressure in the various coils can be adjusted to correspond with the temperature obtaining in the particular portion of the column in which the coil in question is situated. Thus a coil at the top of the column where the temperature is -196°C . would require only a very slightly increased pressure to induce liquefaction of the nitrogen contained therein, while a coil in the oxygen reservoir at the bottom of the column, at a temperature of -182°C . must be supplied with nitrogen at a pressure of several atmospheres, the latent heat of liquefaction in the coils supplying the heat by means of which the mixture on the lower plates of the column is fractionated.

Losses of cold due to radiation and imperfections of exchange are compensated by the liquefaction by expansion of a further quantity of nitrogen, this forming the second source of the separating liquid referred to above.

The system described has been installed on a scale giving 400 cubic metres of nitrogen and 100 cubic metres of oxygen per hour and has proved extremely satisfactory both from the point of view of the purity of the gases produced and by reason of the abnormally low power required for operation as compared with other systems.

Passing from the manufacture of nitrogen to that of hydrogen, it will be seen as the result of even superficial calculation that the cost and purity of hydrogen constitute the key to an economical synthesis of ammonia.

Rejecting electrolytic hydrogen on account of its high cost, there exist various methods of preparing hydrogen in a more or less pure condition from water gas. By the so-called continuous method, water gas and steam are passed together over a catalyst, consisting usually of activated iron oxide, when by the interaction of the carbon

monoxide of the water gas with the steam, the carbon monoxide is replaced by an equal volume of hydrogen according to the equation:—

The carbon dioxide thus produced is absorbed by compression on to water, hydrogen sulphide and other impurities being removed by iron oxide purifiers of the usual type. It is found in practice, however, that the above reaction is never complete, however great the excess of steam, and that the hydrogen produced contains considerable quantities of carbon monoxide, which is of course not absorbed by the ordinary purifiers. This may be eliminated by treatment with calcium carbide, or by compression on to heated soda lime with the formation of formates.

The same objectionable presence of carbon monoxide occurs in hydrogen prepared by the low temperature separation of water gas, by reason of the very appreciable vapour pressure of carbon monoxide even at temperatures approaching its solidifying point.

Carbon monoxide occurs also in hydrogen manufactured from water gas by the intermittent process, i.e., by the alternate steaming and reduction of iron. It is found in this method of hydrogen production owing to the instability of carbon monoxide at high temperatures, which decomposes according to the equation, $2\text{CO} \rightleftharpoons \text{CO}_2 + \text{C}$. The carbon produced is deposited on the iron contact mass during the reducing phase and reacts with the steam subsequently introduced, with the reformation of carbon monoxide during the steaming operation, this carbon monoxide contaminating the hydrogen. $\text{C} + \text{H}_2\text{O} = \text{CO} + \text{H}_2$.

We find, however, that the intermittent method, which in its usual form gives hydrogen containing from 1 to 2% of carbon monoxide, may be modified in such a way as to give hydrogen of the high purity of electrolytic hydrogen, the cost remaining approximately the same as for the ordinary impure water gas hydrogen, by utilising for reduction, instead of water gas, a gas containing sufficient carbon dioxide to prevent the separation of carbon according to the above equation. This reducing gas is obtained easily and cheaply by a modification in the method of manufacturing the water gas.

We obtain in this way hydrogen completely free from carbon monoxide and containing as its sole impurity only a little nitrogen, while by suitable modifications of the method of manufacturing even this nitrogen content may be brought down in such a way that hydrogen of 99.9% purity and even higher is produced directly from water gas without any subsequent purification save that afforded by an iron oxide-line purifying box of the usual type. This complete elimination of nitrogen is, however, of course not necessary for ammonia, but is desirable where the hydrogen is to be used for other purposes, for instance for the hardening of fats.

The following typical analyses illustrate the purity of the hydrogen produced by our process, sample 1 being manufactured without special precautions against nitrogen content, sample 2 with such precautions.

Sample 1. Sample 2.

	%	%
Hydrogen	99.81	99.94
Carbon monoxide	0.00	0.00
Carbon dioxide	0.00	0.00
Nitrogen	0.19	0.06
	100.00	100.00

For the synthesis of ammonia itself, nitrogen and hydrogen, mixed in the proportions required, are compressed to a high pressure in order to increase the equilibrium value for ammonia at the temperature at which the catalyst becomes active, this pressure having as its second effect a very considerable increase in the reaction velocity of ammonia formation.

Since the power required for the compression of a gas from a pressure, P_1 to a second pressure, P_2 , is given by the equation,

$$W = k \log \frac{P_2}{P_1}$$

while the equilibrium ammonia content for a given temperature varies approximately directly as the pressure, it follows that from the point of view of compression economy it is advantageous to work at as high a pressure as is compatible with the strength of materials and smoothness of operation. It is not, however, possible in practice to work at a much higher pressure than 200 atmospheres, and we find 180 atmospheres to be a very suitable working pressure. The very considerable increase in reaction velocity at increased pressure is, further, an additional reason for the use of as high a working pressure as possible.

The catalysts which are available for the promotion of the synthesis, neglecting rare metals of the platinum group, consist of uranium and iron. Uranium, while capable of giving decidedly higher yields of ammonia per passage than iron, possesses the drawback of being only prepared and regenerated with difficulty and of being rapidly rendered inactive by traces of water or of air in the reaction gases.

For this reason we find it preferable to employ, as is done in Germany, iron containing traces of other bodies as promoters, taking advantage especially of the cumulative action of two or even more promoters combined simultaneously in the catalyst.

In view of the lack of published results as to the actual percentage of ammonia obtained in practice from iron catalysts, the following typical figures for the relation between the time of contact of the nitrogen-hydrogen mixture with the catalyst and the ammonia percentage for an iron-potash catalyst may perhaps be of interest. The third column gives the yield of ammonia in kilos, per hour per cubic foot of catalyst space, provided that the ammonia formed is totally removed in the course of circulation, a condition which may be very nearly approached by employing a refrigerator almost at the solidifying point of ammonia ($-77^\circ\text{C}.$) with a rate of circulation such that the ammonia percentage in the gas is not too low. The temperature in this case was, as is usual, not uniform throughout the catalyst column, but varied from about $650^\circ\text{C}.$ at the beginning of the column to about $600^\circ\text{C}.$ at its end.

Time of contact with catalyst.	Ammonia in gas, %.	Yield of ammonia in kilos, per hour per cub. ft. of catalyst space.

26 "	1.4	3.03
66 "	2.7	2.33
105 "	3.1	1.78
18 mins.	3.7	0.89

The most economical rate of working in practice will, from the point of view of power, not necessarily be that at which the highest yield of ammonia per hour is obtained, but will be modified by the efficiency of the heat and cold interchangers and by the completeness of the elimination in the refrigerator of the ammonia formed.

Since the method employed for the complete conversion of the compressed hydrogen-nitrogen mixture into ammonia consists in passing it alternately over the heated catalyst and through this refrigerating system respectively, with alternate formation of a certain percentage of ammonia and its removal in a liquid condition, the cost of operating the process, starting with the compressed gases, consists therefore of the supply of and abstraction of sufficient heat to compensate for radiation and for the deficiencies of the heat and cold exchangers, the efficiency of the heat exchanger being very considerably increased by the by no means negligible heat of formation of ammonia itself. For the economic efficiency of the process too great care cannot therefore be paid to the construction of the exchangers connected with the heated reaction vessel and with the refrigerator respectively.

The maximum temperature which can be employed in the refrigerator is determined by the ammonia content of the gas to be separated, and by the pressure at which the synthesis is being carried out, it being necessary, since the first portions of the ammonia are formed more rapidly than successive increments, to effect as complete as possible a removal of all ammonia formed before re-passing the residual gases through the catalyst column. The following table gives the percentage of ammonia theoretically left in a gas at 150 and 200 atmospheres respectively after passing through a refrigerator at the temperature shown.

Temperature.	150 atm.	200 atm.
$^\circ\text{C}.$	%	%
0	2.7	2.1
-10	1.9	1.4
-20	1.2	0.9
-30	0.76	0.57
-40	0.47	0.35
-50	0.25	0.19
-60	0.13	0.1

The construction of the ammonia retorts presents considerable difficulty not only on account of the high pressure, together with a temperature approaching a red heat, but especially by reason of the rapid deterioration of the wall of the vessel under the influence of the ammonia mixture at elevated temperatures. In order to reduce this undesirable effect to a minimum the reaction vessel may be constructed of a material as resistant as possible to the action of ammonia and surrounded by a nitrogen jacket at the same pressure as that to which the nitrogen-hydrogen mixture in the catalyst chamber is subjected, the whole being surrounded by a wall capable of resisting the pressure, or other precautions must be taken so that the wall which bears the pressure does not become weakened. The manner in which a retort bursts, when this undesirable accident occurs, is a matter of considerable interest to the operator. A burst (as distinguished from an explosion due to admixture of air) results, as far as our experience goes, in a clean split, unaccompanied by fragments. We, nevertheless, take every precaution against accidents, especially with full sized retorts, by placing the reaction vessels in pits preferably out of doors.

plant until a mixture results containing oxygen in proportion sufficient for explosion. We ourselves have given very considerable attention to the subject of the most suitable methods of heating, and are adopting a system which seems to combine simplicity of working with a high degree of safety.

Passing to a short consideration of the economic side of the process, the cost per ton of synthetic ammonia may be summarised from a point of view of energy in the statement that about 5½ tons of fuel suffices both for the production of the necessary hydrogen, and for the generation of the power required for nitrogen production, for compression, circulation, refrigeration, etc. The labour factor in the process is small, but on account of the comparatively high initial cost of the plant, the dead charges per ton of ammonia work out at rather a high figure. The cost of synthetic ammonia under normal conditions in this country should work out at about £10 to £12 per ton.

The synthetic ammonia, when produced, has for the majority of uses to be fixed as an ammonium salt by means of a suitable acid, or it may be oxidised to nitric acid, which may itself, if required, be used for ammonia fixation. It is at present usual to fix ammonia as the sulphate, either by

OXIDATION OF AMMONIA.

Relative efficiency of iron catalysts containing various promoters.

The choice and adoption of a suitable method of heating is by no means easy. Electric heating presents drawbacks in practice, some of which are not apparent on theoretical grounds and for this reason a system of heating has been adopted in Germany according to which air is injected into the catalyst chamber in such a way that the requisite reaction temperature is reached and maintained by internal instead of external combustion. The method possesses the advantage of making possible the use of retorts which are simple in construction, but is, on the other hand, somewhat liable to give rise to explosions owing to incomplete combustion of the comparatively small amount of air necessary to maintain the temperature, this air, if not burnt, by reason of a too low temperature in the retorts or for other reasons, accumulating throughout the entire

direct neutralisation or by interaction with other sulphates, such as calcium sulphate, without the use of free sulphuric acid.

Ammonium nitrate possesses certain advantages by reason of its high nitrogen content and particularly because no extraneous acid is necessary for its manufacture. It is, however, deliquescent and for this reason cannot be transported in sacks.

The oxidation of ammonia to nitric acid in presence of platinum was discovered by Kühnmann as long ago as 1830. The process has, however, only become of technical importance since its development by Ostwald, who in 1902 proposed as a catalyst compact platinum covered with platinum black, the ammonia and air being led over the catalyst with a high velocity in order to minimise decomposition of the oxides of nitrogen formed by the oxidation.

The process, as carried out at the present day, takes three forms :—

1. Oxidation by means of a platinum plug (Ostwald's process).

2. Oxidation by means of an electrically heated platinum net.

3. Oxidation by means of base metal catalysts. According to the Ostwald process a mixture of air and ammonia is passed along a heat inter-changer at the end of which a platinum plug is situated. The yield is good, averaging 90% or even higher, but the regulation of temperature is not so easy as in the second type of platinum plant in which electrical heating is employed. The main Ostwald patent has now expired. The use of an electrically heated net of compact platinum is finding increasing favour and presents many advantages over plant of the Ostwald regenerative type.

It may be preferable at this stage, instead of discussing the various more or less well-established plants employing platinum, to illustrate briefly the results which are obtainable with base metal catalysts taking, as typical examples of these, catalysts consisting of iron containing various promoters, and considering for the present only binary mixtures. The present war restrictions prevent a full description being given of the exact plant and conditions used for the oxidation, but the results about to be described show most decidedly that satisfactory results may be obtained without the use of platinum. We employ for the oxidation of ammonia not only air but also air enriched with the oxygen obtained as a waste product from our nitrogen plant, or even pure oxygen, the slightly increased cost of materials being more than compensated by greatly increased output and by other even more important factors.

The activating influence on iron of certain bodies such as bismuth or copper was well known at the time we began working in this direction, and the results obtained during preliminary tests with known catalysts amply justified a systematic study of the activation of iron for the oxidation of ammonia. Thus ammonia, mixed with ten volumes of air (containing sufficient oxygen for complete oxidation) gave in a preliminary experiment a yield of nitric acid equal to 90% of the theoretical.

The following typical results were obtained at 700° C., the ammonia being supplied with an amount of oxygen sufficient but not in excess of that required for its complete oxidation to nitric acid :—

It will be seen on referring to the curves that the efficiency of pure iron for the oxidation of ammonia is very appreciably raised by the addition of cerium, thorium, bismuth, tungsten, or copper, the time of contact necessary for the maximum yield of nitric acid varying, as would be expected from the complicated nature of the reaction, with the particular promoter used. Thus this optimum time of contact is, for the conditions employed, about 0.01 second for bismuth-iron, 0.015 second for cerium-iron, and 0.02 second for iron-thorium. Lead exerts a curious flattening influence on the curve, the yield of nitric acid being almost independent of the time of contact.

Antimony, from its relation to bismuth, might have been expected to exert a similarly high activating effect. On testing this, however, transitory high results were obtained (91% yield with a time of contact of 0.02 second) but probably owing to the volatilisation of antimony oxide from the seat of reaction, a curve was obtained, after running for some time, more or less agreeing with that for pure iron.

The alkali metals as typified by potassium hydroxide appear to have little effect on the activity of iron, while calcium was found to depress very considerably the maximum yield of nitric acid, the same effect being obtained with zinc and with manganese.

Passing to a consideration of the economic side of the manufacture of nitric acid by the oxidation of ammonia, it will at once be seen that by virtue

of the high speed of passage of the reaction gases over the catalyst, a relatively small catalyst chamber will suffice for the oxidation of a comparatively large amount of ammonia per hour, and that secondly, since practically no power is required for the operation, the actual conversion costs, exclusive of that of the materials necessary, will be low. The power required for the production of one ton of nitric acid from ammonia should not exceed 0.015 kilowatt-year, exclusive of the cost of condensation and of concentration, a process which we are carrying out economically without the use of sulphuric acid.

Finally it may be of interest to compare, from a point of view of power, the relative efficiencies of the three most important methods for the fixation of atmospheric nitrogen, namely, the arc process, the cyanamide process, and the direct synthesis of ammonia from its elements.

In making such comparison it will be seen that in the arc process electrical energy alone is involved, while for the direct synthesis of ammonia a mixed requirement of coke (for hydrogen production, steam generation, etc.) and of power (for compression, etc.) is involved. Thus in order to obtain comparative figures it is necessary to translate the coke and other fuel required per ton of fixed nitrogen into units of power. The power equivalent of one ton of coke or coal is the number of units of electrical power which that ton of fuel would be capable of producing if it were utilised for that purpose under efficient conditions. This may be taken at 1500—1600 kilowatt-hours or 0.18 kilowatt-year.

By the arc process one kilowatt-year of power will produce about 600 kilos. of nitric acid or 130 kilos. of fixed nitrogen. For the production of one ton of fixed nitrogen (as cyanamide) by the carbide-cyanamide method, about two kilowatt-years of power plus 3—3½ tons of coal and other fuel are required, making a total power (converting coal into kilowatt-years as above) of 2.6 kilowatt-years per ton of fixed nitrogen. In other words one kilowatt-year by the cyanamide process will fix 380 kilos. of nitrogen as compared with 130 kilos. by the arc process.

Turning to the power required for the direct synthesis of ammonia, 6½—7 tons of fuel (coke and coal) are required for the generation of the necessary hydrogen and for the production of all power required for the fixation of one ton of nitrogen as ammonia, including the separation of the nitrogen itself from the atmosphere. Converting fuel into power, as before, about 1.2 kilowatt-years are required for the fixation of one ton of nitrogen by direct synthesis of ammonia. Thus one kilowatt-year will fix about 830 kilos. of nitrogen, compared with 380 by the cyanamide method and 130 by the arc process. These figures mean that from the point of view of power and material the direct synthesis of ammonia is more than twice as efficient as the cyanamide process, and more than six times as efficient as the arc process.

These striking results are modified slightly by the difficulty in operating the direct synthesis and by the cost of labour, which is lighter than for cyanamide, together with the necessary dead charges, which are heavier. The direct synthesis of ammonia, however, accompanied where necessary by its subsequent oxidation to nitric acid, presents by far the most economical method of fixing nitrogen at present known, and if only by virtue of the urgent need of the land for cheap, abundant, and non-seaborne fertilisers, deserves every attention from a standpoint of national economy.

DISCUSSION.

Mr. MORLEY remarked that many statements had appeared recently about the danger of

explosion in connection with the Haber process, and he asked if it was possible to make a practical apparatus which would reduce this danger to a minimum. Whilst it was known that the process was practicable on a small scale, with retorts of a capacity of 300 or 400 c.c., he wished to know what was the largest size of retort which could be made commercially.

Mr. MASON asked whether, if it were possible to get cheap power, electrolytic hydrogen would be a possibility.

Mr. WEBB asked whether Dr. Maxted adopted the ordinary system of absorption by means of the water towers, or whether an alkali separation or some other system was used.

Dr. MAXTED, in reply, said the danger of an explosion as distinguished from a burst could be avoided. The Germans were making ammonia to the extent of a million tons a year by the process. With regard to electrolytic hydrogen, he pointed out that most gases which would generate power would generate hydrogen, and it would be more economical to use them in the latter way. His firm was not using the usual absorption methods.

THE CHEMISTRY OF VULCANISATION.

BY D. F. TWISS, D.S.C., F.I.C.

Introductory.

Although the hydrocarbon nature of rubber was realised before the discovery of the process of vulcanisation, analysis in approximate agreement with the empirical formula C_5H_8 having been made as early as 1822,¹ the careful examination of purified rubber, both from the point of view of composition and of chemical behaviour, was not taken in hand until years after vulcanisation had become an important technical process. Possibly to some extent because of this delay, but also very largely on account of the difficulties of accurate chemical investigation with a non-crystalline substance which is obtained chemically pure only with exceedingly great difficulty and is affected in a remarkable degree by mechanical treatment, there remain yet many points in connection with the rubber industry of which the scientific interpretations are contradictory, vague, or based on quite insufficient evidence. Nevertheless, more especially during the last ten years, extraordinary advances have been made in the chemistry of rubber.

As was first clearly demonstrated by Gladstone and Hilbert² the unsaturation of the caoutchouc molecule is such that two atoms of chlorine or bromine may be added for each C_5H_8 group present, any further introduction of halogen occurring only by displacement of hydrogen. More definite information as to the intra-molecular structure of rubber was supplied by the investigations of Harries. As a result of these and other researches the caoutchouc molecule is to-day regarded as composed of a succession of $-CH_2-C(CH_3):CH-CH_2-$ groups linked together into a ring of uncertain dimensions.³ This constitution is in good accord with the possibility of the polymerisation⁴ of isoprene, $CH_2:C(CH_3).CH:CH_2$ ⁵ to caoutchouc, the movement of the double bond being commonly observed in a conjugated system of ethylenic linkings $-C=C-C-$ on the addition of a univalent atom or group at the first and fourth carbon atoms.⁶

As would be expected of an unsaturated hydrocarbon (C_5H_8), containing an ethylenic linking in each C_5H_8 group, caoutchouc forms additive compounds with many of the reagents for olefinic substances, e.g., with the halogens⁷, the halogen hydracids⁸, "nitrogen trioxide"⁹, nitrogen dioxide¹⁰, ozone¹¹, and chromyl chloride¹².

It is at first sight almost surprising that until recently so few of the reagents for olefinic compounds

have been even tentatively suggested as agents for vulcanisation. The use of chlorine, bromine, iodine, and aqueous hypochlorous acid was suggested fairly early for this purpose¹³, whilst in more recent years, benzoyl peroxide, which might be expected to react additively at a double bond as its parent compound hydrogen peroxide is known to do, and various aromatic nitro- and polynitro-compounds, which are known as a class to form additive compounds with olefinic substances¹⁵, have been stated to convert rubber into a condition resembling vulcanised rubber¹⁶. The resemblance, however, is so remote that no serious hope can at present be entertained for a successful application of these substances to technical vulcanisation, although the result is certainly of interest, as showing that such reagents can produce a change in the physical characteristics of raw rubber.

The general chemical behaviour of caoutchouc would lead to the expectation that this substance would react fairly readily with sulphur chloride and also with sulphur, the former of which has for many years been known to yield additive compounds e.g., $(C_5H_7)_2S_2Cl_2$, with olefines¹⁷. As is well known, the technical vulcanisation of rubber is invariably effected by one or other of these substances. Additional ingredients may be and commonly are added to the rubber in order to ensure desired physical characteristics such as colour, definite specific gravity, coarseness, strength, or even (in the case of vulcanisation with sulphur) increased rate of vulcanisation, but the vulcanising effect itself is produced by sulphur or sulphur chloride. At a casual glance it is sometimes possible to overlook the presence of sulphur in some published rubber mixings on account of its introduction in "antimony sulphide" or "black hypo" containing a considerable proportion of free sulphur or as some proprietary "vulcanising compound" such as an intimate mixture of sulphur and wax.

Cold vulcanisation.

Vulcanisation by means of sulphur chloride is effected at or near the ordinary temperature and is restricted to thin rubber material. The material is dipped into a solution of sulphur chloride in some suitable inert solvent or is exposed to the vapour of such a solution. Parkes, who discovered the method in 1846, used a solution in carbon bisulphide.

Various investigators have submitted this process of "cold vulcanisation" or "cold cure" to scrutiny. An obvious difficulty in the way of accurate interpretation is the fact that cold vulcanising as technically practised is largely restricted to the surface layers and is not uniform in effect at various distances below the surface of the rubber. In consequence of this, the research methods employed have in some cases necessarily deviated somewhat from the technical conditions, the most definite results having been obtained from the action of excess of sulphur chloride on purified rubber in solution in benzene¹⁸, when, whatever the excess of sulphur chloride applied, the product approximated to the composition $(C_{10}H_{16})_2S_4Cl_2$, which is analogous to that of the additive compound derived from sulphur chloride and the simple olefines, such as ethylene itself (see above). In view of the complications likely to arise from the presence of organic impurities natural to raw rubber and from the liability of sulphur chloride to vary in composition and to be affected by even slight traces of moisture which may cause the formation of insoluble sulphur (see later), the rather divergent results of earlier investigators¹⁹ are not surprising. There can be no reasonable doubt that the action of sulphur chloride on rubber in cold vulcanisation is definitely chemical and that the final product is a compound of the composition just stated. As to what may happen to the general mass of rubber when in technical practice a piece of rubber sheet

is allowed to combine with a quantity of sulphur chloride quite insufficient to convert it wholly into the final additive product, is largely a matter of speculation which receives further mention below.

Heat vulcanisation.

The discovery of the great improvement in the mechanical properties of rubber induced by mixing with sulphur and submitting to a temperature between 135° and 160° C. (Goodyear, 1839) or by dipping thin rubber articles into molten sulphur (Hancock, 1843) preceded Parkes' discovery of cold vulcanisation, but although the process of "heat vulcanisation" or "heat cure" is more general, its phenomena are even more complex and obscure.

That the chemical process in heat vulcanisation is purely additive was clearly demonstrated by Weber²⁰ who was also able to show that the limit of vulcanisation is reached when the proportions of rubber and combined sulphur approximate to the formula $C_{10}H_{16}S_4$, an observation which has received definite confirmation from the results of several other investigators²¹. Weber's views as to the formation of definite intermediate compounds, based on the assumptions that 2% forms a minimum proportion of sulphur for a satisfactorily vulcanised soft rubber and that certain discontinuities in his curve showing the percentage of combined sulphur plotted against the period of vulcanisation at constant temperature were of real significance, have, however, proved to be incorrect and due mainly to inaccuracies inherent to his experimental method. The course of the vulcanisation process under constant conditions is quite regular and smooth, the rate of combination of rubber and sulphur decreasing quite gradually as the amount of available free sulphur (and rubber) diminishes²².

Although the process of heat vulcanisation presents a more complex problem than that of cold vulcanisation, it lends itself much better than the latter to scientific investigation on account of the possibility of so selecting the temperature that the reaction proceeds with conveniently measurable velocity. The velocity of combination of sulphur and rubber is increased by raising the temperature, the temperature coefficient²³ of approximately 2.7 for 10° falling within the usual limits of the value for a chemical reaction.

The phenomena during the heat treatment of a mixture containing rubber and sulphur will obviously include physical changes such as the melting of the sulphur and the dissolution of the molten sulphur in the rubber; by the latter the sulphur will become more uniformly diffused throughout the rubber, whereas previously it was localised in solid particles²⁴. Indeed, in the Hancock process it is evident that the diffusion of the molten sulphur into the rubber must form an essential preliminary stage to vulcanisation beneath the surface. The melting and dissolving of the sulphur²⁵ have been followed under the microscope as also has the inverse crystallisation of the excessive dissolved sulphur²⁶, the latter, indeed, being well known in the so-called "blooming" or "sulphuring up" of heat vulcanised goods containing a considerable quantity of uncombined sulphur.

The adsorption theory.

With an additive chemical reaction between sulphur and a colloidal substance like rubber accompanied by a reversible solution process, the periodic recurrence of the suggestion that the vulcanisation process is not chemical but merely a physical adsorption phenomenon, is not surprising. In 1910, Wo. Ostwald²⁸ revived this theory with all the available favourable evidence, and his paper has caused the evidence to be sifted so thoroughly as entirely to dispose of the idea that vulcanisation can be a purely physical change. Ostwald's paper consisted of a review of the work of a few

earlier investigators with an explanatory commentary biased in favour of the adsorption theory. Most of the arguments, however, suffer under close examination²⁹ and have received severe criticism, especially by Loewen³⁰. Apart from accepting and applying to the purpose of his theory the peculiarities in Weber's experimental results which have since been proved to be due to mere inaccuracies and not to any corresponding abnormalities in the behaviour of the rubber-sulphur mixing²² Ostwald's claim that vulcanisation is reversible,* based on the earlier statement of Höhn, is not in accord with the present impossibility of reproducing "raw rubber" by the "regeneration" or "reclaiming" of vulcanised rubber (see later), whilst his calculation that the results of Hinrichsen and Stern³¹ and of Hübener³² on the combination of rubber and sulphur are in agreement with the adsorption formula $\frac{x}{a} = kc^n$

where x represents the quantity of sulphur absorbed, c the original concentration of the sulphur, and a the quantity of the adsorbent, whilst k and n , are constants, is vitiated by the fact that he has misunderstood the figures quoted by Hübener from Hinrichsen and Stern and has used for the calculation figures corresponding in reality with an equation $\frac{x}{a^2} = kc^n$. The

correct figures are not confirmatory of the view that the process is one of adsorption³⁰. In like manner, the statement that in vulcanisation the sulphur never passes entirely from the free condition has been proved incorrect³⁴, whilst the remarkable alteration in physical properties observed in the formation of vulcanite and the fact that vulcanised rubber yields a bromo-derivative³³ and a nitrosite³⁴ containing combined sulphur, are great obstacles in the way of the acceptance of the purely physical conception of vulcanisation. Ostwald's sweeping assertions with respect to the nature of vulcanisation have caused the chemists to establish their faith on a firm experimental basis, and have thereby served to strengthen the position of the chemical theory.

Other theories.

Various modifications of the chemical theory of vulcanisation have been suggested. Erdmann proposed the explanation that sulphur acts on rubber in a triatomic condition, which he describes as thiozone by analogy with ozone; this theory³⁵, however, lacks experimental confirmation and, in the light of our knowledge of the allotropic forms of sulphur, is improbable.

Although the occurrence of chemical reaction between rubber and sulphur during vulcanisation cannot well be denied, this change may not be exclusively chemical in nature, and endeavours, with much in their favour, have been made to represent vulcanisation as a combination of a chemical change with an adsorption process. The suggestion that the free sulphur is adsorbed before vulcanisation³⁶, appears unnecessary and is less attractive and less probable than that the chemical product of vulcanisation is adsorbed into the remaining rubber after its formation. Examination of various technical soft products vulcanised by the heat process shows that the amount of sulphur in combination with the rubber is variable³⁷, but almost without exception falls somewhere between the limits of 2% and 7% calculated on the rubber present. Bearing in mind that the only definite chemical product of heat vulcanisation is of the composition $C_{10}H_{16}S_2$ (see above) containing approximately 47% of

sulphur calculated on the rubber, it is obvious that technically vulcanised rubber represents no definite chemical compound but probably a solution or adsorption product of a more highly vulcanised product, possibly $C_{10}H_{16}S_2$, in an excess of very slightly vulcanised or sulphur-free rubber, the physical characteristics of the latter being modified by the presence of the adsorbed compounds³⁸. Ostromisslenski¹⁶, indeed, who regards his experimental results on the effect of aromatic nitro-compounds and of benzoyl peroxide as favouring such a view of vulcanisation, states that the vulcanisation of raw rubber can be effected by the addition of a small percentage of already formed caoutchouc hydrochloride or tetrabromide and subsequent heating, but his conception of a satisfactorily vulcanised rubber is rather wide. According to this view, vulcanisation in the sense of the acquisition of new physical properties by the general mass of the rubber, although not independent of the chemical combination of sulphur with part of the rubber, occurs subsequently to this combination and the small proportion of additive compound produced may be regarded as the direct vulcanising agent acting by "catalysis." The alteration in the main portion of the rubber, consequently, would be accompanied by no change in composition and must be ascribed to some alteration in the molecular condition which may be a polymerisation. Axelrod³⁹ had earlier propounded a somewhat similar theory involving the assumption that vulcanisation comprises two processes, one of which is the combination of sulphur and rubber. As is well known, heat tends to soften rubber whereas vulcanisation tends to produce the contrary effect. In Axelrod's explanation, the vulcanisation process depends on a primary softening, commonly described as "depolymerisation" or in a less committal manner as "de-aggregation"⁴⁰ of the rubber, followed by a "repolymerisation" under the influence of combination with sulphur⁴¹. Colour is given to this view by the fact that after the whole of the free sulphur has disappeared into chemical combination, further heating produces a weakening and softening effect; this indeed occurs to a greater or less extent in the "reclaiming" or "regeneration" of vulcanised rubber scrap by heating with acid or alkali, in which the material is again rendered sufficiently soft and tacky to be incorporated afresh as a diluent in rubber mixings⁴². Whether the so-called depolymerisation and repolymerisation as postulated in Axelrod's theory actually do occur alternately and repeatedly is not proven and it is possible that the two processes are independent and merely concurrent. The likelihood of modifications in the physical nature and molecular condition of rubber during vulcanisation is heightened by the results of Harries, who has shown not only that ordinary raw rubber behaves as if composed of three mutually interconvertible varieties⁴³, but also that in ordinary soft vulcanised rubber the major portion of the rubber is not in combination with sulphur although it possesses different physical and chemical characteristics from raw rubber³⁸. The very considerable change which occurs when a newly vulcanised rubber is allowed to "mature" indicates that the alteration in mechanical characteristics induced by vulcanisation may continue for a short time after the chemical change is complete⁴⁴.

This hypothesis of physical change as induced by the chemical action occurring in vulcanisation has been extended to the process of cold vulcanisation⁴⁵ in which the quantity of combined sulphur chloride is likewise quite insufficient to convert the rubber entirely into the final additive compound.

It should, however, be clearly realised that these views in no wise support the adsorption theory of Ostwald, whose claim was that no chemical com-

* For a reply to the alternative argument that an adsorption process need not be reversible, as instanced by the case of methyl violet and charcoal, see Hinrichsen, *Zeitsch. Chem. Ind. Koll.* 1911, 8, 245.

bination whatever occurred between the rubber and the sulphur, but that the latter was merely adsorbed by a purely physical process.

Rate of vulcanisation.

The rate of vulcanisation of rubber is of importance for two distinct reasons. It is desirable in works practice that the period necessary for satisfactory vulcanisation should not be too prolonged, but on the other hand, it is very important that the behaviour of various consignments of rubber should be as uniform as possible so as to permit a standardisation of procedure without need for constant re-adjustment.

Examination of the rate of cure may be made from two points of view, viz., by measurement of the resulting physical effect⁴⁶ and by determination of the extent to which sulphur enters into combination when a mixing of standard composition is given a definite "cure." With a series of samples of rubber both methods as a general rule give results which fall into the same order, but the physical method possesses an advantage in simultaneously giving an indication of the inherent mechanical value of the rubber. Investigation from both points of view concurrently is certainly most satisfactory.

In the former method a standard mixing, frequently sulphur 10: rubber 90, is adopted, and this is vulcanised for a series of gradually increasing periods at a constant temperature (e.g., in steam under 50 lb. pressure), after which the mechanical properties of strength and stretch of the samples are measured, and the period of vulcanisation necessary to produce optimum mechanical properties decided from the results (see curves 1 and 2).

The coefficient of vulcanisation, i.e.,
$$\frac{\text{combined sulphur} \times 100}{\text{rubber}}$$

corresponding with the optimum period generally has a value of about 5, but it is improbable that such a coefficient would prove the most satisfactory for all purposes⁴⁷. The results, however, are usually intended only for comparative purposes, and it is easy by their aid to detect a rubber of unusual quality either in mechanical strength or in rate of vulcanisation.

Natural accelerators.

Rubber is not a pure hydrocarbon substance, but is contaminated with natural resins⁴⁸ and protein substances⁴⁹, and it has been found

that these foreign ingredients appreciably affect the rate of vulcanisation. If the resins⁵⁰ and more especially the protein matter⁵¹ be removed from the rubber the rate of vulcanisation is decreased in a marked manner, whereas if rubber is enriched in natural proteins by dissolving away part of the rubber hydrocarbon with benzene, the rate of vulcanisation of the protein-enriched rubber is enhanced. Possibly as an outcome of this discovery, the addition of a mixture of lime and albumin⁵² has been patented as a method for accelerating vulcanisation, but lime itself catalyses the vulcanisation process, and the increase in the rate of "cure" may not be due entirely to the albumin.

In the earlier days of the plantation rubber industry, considerable stress was laid on the variability in the rate of vulcanisation of "plantation Para" rubber as compared with the wild Para rubber. More recently, Eaton and Grantham, working in Malaya, have been able to discover the chief cause of this variability, and, indeed, to indicate the possibility of a step of great value in the production of raw rubber. In the ordinary plantation procedure, the rubber coagulum, obtained from the latex, is washed and creped with the intention of removing the serum as completely as possible; if, however, the soft slabs of coagulum are allowed to "mature" for several days before the retained serum is expressed, it is found that the resulting rubber vulcanises with unusual rapidity, the effect attaining its limit after a period of roughly seven days before washing and crepeing⁵². The rubber from such matured slabs when mixed with 10% of sulphur attains its optimum condition of vulcanisation in approximately one-third of the ordinary period.

Curves 3 and 4 show the behaviour of rubber prepared in this way as compared with the ordinary qualities of plantation rubber from the same estate; with the period of vulcanisation which gives the optimum results for the ordinary qualities, the special rubber is excessively over-vulcanised.

Tensile strength by percentage elongation.

The cause of this difference has been traced by Stevens⁵³, who has shown that during the maturing process, the protein matter of the retained serum undergoes decomposition with formation of organic bases which remain absorbed even after washing. Such bases are well known to possess considerable catalytic activity towards the heat vulcanisation of rubber (see later).

Although the difference in rate of vulcanisation as compared with rubber produced in the ordinary manner is less marked in technical mixings, the great advantage of a uniform supply of such rapidly vulcanising rubber for special purposes

will readily be recognised, and experiments as to the possibility of producing large quantities of rubber with a uniform high rate of vulcanisation will prove of great interest.

Inorganic accelerators.

Goodyear himself realised that the process of vulcanisation could be hastened by the inclusion of calcined magnesia in the rubber-sulphur mixing, and the use of this substance, as also of litharge and calcium hydroxide (and, to a less extent, of magnesium carbonate), has for many years been a recognised device of the manufacturer to shorten the period necessary for the vulcanisation of his mixings. Various suggestions have been made to explain the effect of these substances, but few bear critical examination; thus conversion into sulphide followed by alternate formation and

molecular proportions by independent chemical reactions as an essential part of the vulcanisation process, the facts that sulphurous acid and acid sulphites retard vulcanisation⁶⁰, and that colloidal sulphur does not give accelerated vulcanisation (see below) are diametrically opposed to this theory.

Apart from the above basic accelerators, the only inorganic accelerators which have been proposed are various metallic iodides, antimony iodide in particular⁶¹; in this case it is possible that the effect may have been due to the conjoint action of sulphur and iodine on the rubber; this method of acceleration appears never to have come into general practice.

Organic accelerators.

In recent years a notable advance in the technique of heat vulcanisation has been the introduction of organic bases as accelerators. The first published statement as to the use of an accelerator of this type appears to have been in the patent specification protecting the application of the strongly alkaline base piperidine, $C_4H_{10}N$ ⁶²; a claim by Spence to priority⁶³ in the use of this and other organic accelerators is still awaiting promised details. After piperidine, the use of many organic amines was patented⁶⁴, a final claim covering the application of all organic bases of dissociation constant exceeding 1×10^{-4} . It is inconvenient to apply some of these bases in the free condition on account of their volatility, which may cause loss by evaporation or also may tend to produce porosity in the vulcanised rubber; this disadvantage may be obviated by previous conversion of the base into the corresponding carbamide⁶⁵, dithiocarbamate, carbamate, or carbonate derivative. Indeed, I have also found that the unstable base aminoguanidine forms an excellent accelerator when applied in the form of its more stable bicarbonate salt⁶⁶, whilst ammonium bicarbonate is also very effective.

One of the most powerful of these organic catalysts is aldehyde-ammonia, the effectiveness of which far outweighs what might be expected of its ammonia content, and must be regarded as a specific property of aldehyde-ammonia itself. Indeed, from the purely chemical point of view also, the behaviour of aldehyde-ammonia is somewhat abnormal, and although it must be regarded as a definite organic base its constitution is not settled beyond doubt⁶⁷.

It is a remarkable circumstance that almost the whole of the known effective* organic accelerators are basic, a rough proportionality apparently existing between their activity and their alkalinity, relatively feeble bases like aniline and methylaniline having little influence on the rate of vulcanisation. The mineral accelerators mentioned earlier are also alkaline or basic substances, and it appears highly probable that this is no mere coincidence but that the two classes of substances in common owe their influence in some way to their basic character. If this is really so, the alkali hydroxides should also be strong accelerators and experimental examination proves the correctness of this argument. For a long time it has been known that regenerated rubbers obtained by heating with alkali sometimes vulcanise with exceptional rapidity⁶⁸; Martin⁶⁹ also has demonstrated that the introduction of a small percentage of powdered caustic potash into a mixture of rubber and sulphur causes a greatly increased rate of vulcanisation, whilst Eaton more recently has shown that a similar effect is produced with rubber which when freshly coagulated has been soaked in

Tensile strength by percentage at break.

decomposition of polysulphides, by which process the sulphide acts as a "sulphur carrier"⁶⁴, is improbable, because the corresponding sulphides are less efficient than the oxides or hydroxides, whilst it is also unlikely that magnesium oxide is largely converted into sulphide during vulcanisation; even the accelerating effect attributed to antimony sulphide⁶⁵ is largely due to misconception arising out of the effect of the free sulphur commonly present in this material.

Litharge has been a favourite subject for speculation. Its effect has been attributed, at different times, to its aiding the conduction of heat into the rubber mass⁶⁶, and to the heat evolved by its oxidising action on the rubber resins or on the hydrogen sulphide arising from the interaction of the resins and sulphur⁶⁷. The rise of temperature due to such liberation of heat would cause a corresponding increase in the rate of reaction between sulphur and rubber, and it is probable that a thermal effect of this kind is produced by the direct or indirect action of the lead oxide on the sulphur⁶⁸; the occurrence of a thermal effect in litharge mixings can indeed be detected by direct measurement of the temperature of the mass during vulcanisation.

A highly fanciful explanation of the effect of litharge and other oxide accelerators has been proposed lately⁶⁹. The heating necessary for vulcanisation is assumed to cause the sulphur to attack the natural resinous matter and proteins and the litharge simultaneously, with formation of hydrogen sulphide and sulphur dioxide respectively. These two gases then react in the recognised manner, and the acceleration of the vulcanisation process is attributed to the exceptional activity of the amorphous sulphur thus produced. Apart from the improbability that two gaseous substances are formed in definite

* It is difficult to understand on what grounds certain substances have been described as accelerators: e.g., see a list of accelerators by King, *Metallurgical and Chemical Engineering*, 1916, 15, 231.

caustic alkali solution. The latter investigation, however, has since withdrawn his recommendation of this process ⁷⁰.

Several years ago, influenced by the fact that the inorganic and organic accelerators were all basic substances, I became of the opinion that both classes of substances exert their influence in a similar manner and that the relative advantage attaching to the use of organic bases depends chiefly, if not entirely, on the fact that these are soluble in rubber and therefore become more uniformly distributed and diffused, whereas the inorganic accelerators, being only sparingly soluble, remain for the most part localised in small solid particles, which, indeed, are frequently visible to the naked eye. For this reason I sought a suitable organic liquid which would dissolve in rubber and also would act as a solvent for an alkali hydroxide, because a solution of this kind would possess marked alkalinity and also would be capable of blending uniformly with rubber, thus reproducing the conditions which obtain when an organic accelerator is used, without any accompanying danger of porosity. The most suitable solvent discovered was glycerol which dissolves sodium hydroxide or potassium hydroxide, probably with formation of the corresponding glyceroxide ⁷¹. The latter alkali is more easily soluble and a solution containing approximately 25% on the total weight is easily obtained. If 1–2% of such a solution (anhydrous) is introduced into a rubber-sulphur mixing, the vulcanisation process is greatly accelerated, the effect being comparable with that of the strongest organic accelerators, as is demonstrated by the figures below. It is also noteworthy that the actual quantity of alkali used approximates closely to the 0.5% recommended for the most effective organic accelerators and that with a rubber-sulphur mixing the resulting vulcanised rubber, in both cases, possesses the same clear, dark, almost semi-transparent appearance.

In earlier experiments, I had endeavoured to effect the uniform distribution of the alkali into the rubber-sulphur mixing by introducing it in the form of a finely-powdered mixture of the alkali with lime, but although the results were certainly gratifying, they were less consistent than those obtained with the glycerol solution.

The following figures give the residual uncombined sulphur after a mixing of 95 rubber: 5 sulphur with the addition of the stated accelerator was vulcanised for 90 minutes at 40 lb. steam pressure:—

Accelerator.	% of Accelerator.	Residual free sulphur %.
(1)	—	3.60
(2) Potassium hydroxide in glycerol	2 (of solution 1:4 approx.)	0.31
(3) Sodium hydroxide in glycerol	2 (of solution 1:8 approx.)	0.61
(4) Anilinoquinidine	1	0.89
(5) Ammonium carbonate ..	1	1.39
(6) Aldehyde-ammonia	1	0.17
(7) <i>p</i> -Nitrosodimethylaniline	1	1.50

As will be observed from the above results, *p*-nitrosodimethylaniline ⁷² does not accelerate very strongly under the conditions chosen. This is due, at least in part, to the fact that the mixing selected contains a relatively low proportion of sulphur. The nitroso-compound is much more effective in mixings containing a high percentage of sulphur and it is probably because mixings containing litharge or antimony sulphide are usually intended to have a good colour and, therefore, in order to prevent excessive “blooming,” are generally prepared with a low percentage of free sulphur, that these have been found to behave less satisfactorily with the nitroso-compound (⁷³).

Mode of action of accelerators.

As the effect of accelerators in general is most distinct in mixings otherwise containing only rubber and sulphur, their action presumably must be by influence on one of the ingredients present, viz., (1) the natural protein and resinous matter, (2) the sulphur, or (3) the rubber hydrocarbon.

The first possibility is eliminated by the fact that the accelerators work equally well with rubber from which the protein matter has been removed, one of their first uses indeed being to render protein-free synthetic rubber capable of more rapid vulcanisation.

With respect to the possibility of acceleration as due to the influence of the catalyst on the sulphur, the suggestion has been made ⁷⁴ that with organic, as with inorganic accelerators, polysulphides are first formed which then effect the vulcanisation of the rubber. As has been explained already, this theory is not altogether satisfactory for the effect of the basic oxides generally.

A possibility which appears to have been previously overlooked, but which at first appeals to the imagination, involves the two allotropic forms of liquid sulphur. Molten sulphur consists of a mixture of mobile yellow *SA* with viscous deep brown *S_μ*, the exceptional behaviour of molten sulphur with alteration of temperature being due to variation of the relative proportions of these constituents ⁷⁵. When molten sulphur is cooled, the *SA* variety gives rise to ordinary soluble crystalline sulphur, whilst *S_μ* produces insoluble amorphous sulphur. In molten sulphur an equilibrium is slowly attained between these two forms, but the existence of *S_μ* is favoured by the presence of acids, whilst alkalis such as ammonia or doubtless organic bases, facilitate the conversion of *S_μ* into *SA*.

The remarkable parallel between this effect of acids and bases on the *SA* \rightleftharpoons *S_μ* equilibrium and that of acids and bases in respectively retarding and accelerating the vulcanisation process, naturally arouses a suspicion as to the existence of some connection between the two sets of phenomena. In order to test this possibility, insoluble amorphous sulphur corresponding with *S_μ* was separated from genuine flowers of sulphur by extraction of the soluble *SA* with carbon bisulphide. Comparative vulcanisation tests were then made with rubber-sulphur mixings employing this insoluble sulphur and ordinary totally soluble sulphur. Although my results actually indicated that *S_μ* combined with rubber rather more slowly than *SA* the difference was relatively slight and quite insufficient to account for the great effect of the organic basic accelerators.

Mixing.	Period of cure at 40 lb.	Residual free sulphur.
Rubber 100: soluble sulphur 10	120 minutes	8.39
Rubber 100: insoluble sulphur 10	120 „	8.81*

* This residual sulphur, after vulcanisation, is found to consist mainly of the more soluble modification.

Although this result disposes of the probability of any real connection underlying the parallel between the action of acids and alkalis in the *SA* \rightleftharpoons *S_μ* equilibrium and in the process of vulcanisation, it is of additional interest as also disposing of Dubosc's suggestion that the action of inorganic catalysts in vulcanisation depends on the production of amorphous sulphur for which he postulates exceptionally great vulcanising activity ⁵⁹.

The immediately preceding considerations to some extent narrow down the enquiry as to the mode of action of the basic accelerators. Either

the sulphur is influenced in some other way than those mentioned, or the effect must be produced on the rubber itself. On account of the colloidal nature of rubber and its obscure "depolymerisation" and "polymerisation," the investigation of the latter alternative is more difficult. Nevertheless, the knowledge that alkalis increase the stability of the independent rubber globules⁷⁶ in ordinary rubber latex and the observation that even coagulated and worked rubber retains traces of a globuloid condition⁷⁷, might be regarded as suggestive of a possibility that alkalis are likely to affect the behaviour of finished raw rubber, e.g., by influencing the inter-conversion of modifications in different states of molecular aggregation and of different reactivity. Such a possibility indeed, would be in accordance with C. O. Weber's observation⁷⁸ that when rubber is masticated with litharge only, in the absence of sulphur, the material undergoes a remarkable change in physical properties.

There is much more room for further investigation on the question of the chemical mechanism of the acceleration of vulcanisation.

Other considerations.

The existence of the above-mentioned soluble and insoluble modifications of sulphur is well worth bearing in mind in other directions. For instance, although it is generally accepted that the free sulphur in an ordinary rubber mixing can, for all practical purposes, be removed completely by continuous extraction for ten hours with acetone, the remaining sulphur being regarded as in combination with the rubber, the above unvulcanised mixing containing "insoluble" sulphur yielded only 27% of its sulphur in this period.

Comparative extractions were made with the two mixings containing respectively soluble and insoluble sulphur, by treating samples with acetone in a continuous extractor at the temperature of the boiling solvent; the rate of extraction is represented in the following curves.

Residual sulphur.

Any conclusions as to the reversibility of vulcanisation based on the possibility of removing sulphur from vulcanised rubber by prolonged extraction⁷⁹ even after as much as twenty hours' previous extraction, are, therefore, unjustified⁸⁰ unless definite proof is supplied as to the absence of "insoluble sulphur." It has also been stated by Bysow that in cold vulcanisation, sulphur and chlorine do not combine with the rubber in equivalent quantities⁸¹, but traces of moisture in the rubber would cause the decomposition of part of the sulphur chloride with formation of some insoluble sulphur and would account for the

apparently disproportionate quantity of "combined" sulphur.

The evidence for the supposed vulcanisation of a rubber-sulphur solution at the ordinary temperature by ultraviolet light⁸² is also unconvincing. From the observation that a rubber-sulphur solution in benzene, when exposed in a thin film to ultraviolet radiation, becomes more viscous and that after evaporation of the solvent, part of the sulphur is not removed by an ordinary ten-hour extraction with acetone, the conclusion has been drawn that the unextracted sulphur has combined with the rubber. However, ultraviolet light is already known to convert dissolved sulphur into insoluble sulphur⁸³ (or S_2 into S_8) and although the S_8 may not separate in visible particles it is quite likely to remain in ultra-microscopic colloidal suspension.* Ultraviolet light also, without the aid of sulphur can render rubber solution more viscous and improve the strength of thin rubber sheet⁸⁴.

The above alterations in the rubber-sulphur solution appear to be quite insufficient evidence of vulcanisation, and the observed changes, at least in part, may consist of independent physical changes in the rubber and sulphur respectively; indeed this possibility appears to receive some confirmation from Bernstein's doubts as to whether the sulphur in vulcanisation becomes chemically combined or merely physically adsorbed⁸⁵.

The preceding review of the chemistry of vulcanisation shows how great has been the activity in this direction, especially during recent years, but will also indicate how wide are the gaps of knowledge which at present are bridged over by mere theories and need to be filled up with a solid mass of experimental evidence.

Many of the results referred to in this paper as obtained by other investigators have been re-examined and confirmed.

For permission to publish the new results included, I am indebted to Dr. J. V. Worthington, Technical Superintendent and Director of the Dunlop Rubber Company, whilst for curves 1 to 4 and for many tests made in connection with points brought under consideration, I wish to express my indebtedness to Mr. A. W. T. Hyde, Head of the Physical Testing Laboratory of the same firm.

DISCUSSION.

Dr. H. P. STEVENS said that he had carried out some experiments with benzoyl peroxide, but had obtained no results up to date which were really comparable with the results obtained with sulphur. On the other hand, he did not think his own research, at any rate, went sufficiently far to enable him to make the statement that benzoyl peroxide could not be used technically, and if Dr. Twiss had made experiments of his own, it would be interesting to hear what the results had been. A point often lost sight of was the effect of temperature on physical tests. In a paper read at the last rubber conference in London, an American investigator, Wormeley, had shown that variation of temperature produced a very large effect on the results of physical tests. He had found, for instance, that a difference in temperature of 20° F.—a difference frequently met with in the test room between summer and winter—produced something like 10% difference in the tensile strength and elongation of the product. Up to now there appeared to be no appliance by which the temperature of the specimen during the test could be controlled. It was also important that previous to testing the specimen should be kept at a constant temperature. With regard to the rapidly vulcanising rubber produced by allowing the rubber to mature, he took it that such a rubber would be of greater value than the ordinary trade rubber as now supplied. During maturing oxidation took place, weakening the surface. It was interesting to hear of the author's experiments with the use of potash and soda. So far as he understood it, the results obtained with such an accelerator were in all respects comparable with those obtained with organic accelerators. There had been an idea that traces of alkali affected the stability, that was to say, the ageing qualities of rubber.

Dr. Twiss, in reply, said he had, as Dr. Stevens suggested, made experiments as to the possibility of vulcanising rubber with benzoyl peroxide and nitro compounds. The products did not compare in strength with technically vulcanised rubber. It seemed to him, however, that it was only a matter of time for substances to be found which would have an effect similar to that of sulphur chloride. As to the samples vulcanised in the presence of the alkali solution in glycerol, in the period that had elapsed since those mixings were vulcanised, now almost three years, a certain weakening was observed, but no greater than in similar mixings containing other accelerators used with considerable success by some manufacturers.

THE SCIENTIFIC NEEDS OF THE RUBBER INDUSTRY.

BY B. D. PORRITT, M.Sc. (LOND.), F.I.C.

If statistics were available to show the numbers of men with scientific training absorbed annually by various British industries during the last twenty years, that of rubber certainly would be found to occupy a very humble position on the list, far below what might be expected in view of its commercial importance, and intricate character. Moreover, it would be apparent that until the last decade a chemist was practically unknown in the majority of factories engaged in this trade. Even at the present time a technical laboratory set aside solely for the purpose of research is a rarity, and the duties of the average rubber chemist still remain essentially what they

were in the days when the advent of the much-abused specification led to the creation of a new subordinate position on the rubber manufacturer's staff.

How is it that while other trades, once equally empirical, are now managed by scientific men on scientific principles, in this important and well-established industry many works can even dispense altogether with the services of a chemist, and only a few firms recognise any necessity for carrying out what can be truthfully described as research? Is there but limited scope for the chemist in the rubber trade or has his day yet to come?

That a need exists for information and methods to ensure the production of a material of uniformly high quality, to increase the factory output, and to avoid mysterious manufacturing troubles will be readily conceded by all who have had practical experience of this intricate colloid industry.

Is the chemistry of rubber sufficiently advanced to enable a laboratory to satisfy fully these requirements? Is it, for example, possible on general principles to assign to any particular rubber mixing the exact conditions of temperature and time of vulcanisation to ensure a sound and durable product, or must the chemist resort to a practical test on a small scale? A chemist entering the rubber trade will speedily become conscious of the limitations of his scientific knowledge and the necessity for solving many of the factory problems by the old-fashioned methods of trial and error. While the laboratory may be accepted by some manufacturers as a valuable adjunct, it is, as yet, not generally recognised as an essential. In most modern industries pure science has either anticipated technology or the two have progressed hand in hand. The rubber industry is different. Its foundation rests upon the discovery of vulcanisation by Goodyear in 1839. To-day, 78 years later, the mechanism of this process and the chemical constitution of the raw material are still subjects for speculation and discussion.

The fact that rubber is a colloid will probably be advanced as an explanation to account for the imperfect state of our scientific knowledge of its properties. This may in a measure be true, but it cannot be pleaded in extenuation of the past and present neglect of research by the trade generally.

Other industries, similarly situated, have not taken up this attitude, and one has but to examine the voluminous literature dealing with the esters of cellulose and study the descriptions of the laboratories of the Eastman Kodak Co. in order to realise the immense amount of work which has been carried out in other branches of colloid chemistry.

Difficulties often may excuse failure but they seldom justify inaction.

The present is a unique opportunity for industries to consider any past difficulties, shortcomings, and failures. Abnormal trade conditions and national needs have for a while deadened trade competition and petty jealousies, and the changes in business and manufacturing methods introduced by stern necessity have forced many a conservative manufacturer to abandon the traditions of a lifetime.

For the moment, industries, corporations, and individuals are disposed to abandon obsolete methods, to consider novel suggestions, and to co-operate for mutual benefit. Thanks to this new spirit, many of our industries are now busy putting their affairs in order. Will the rubber trade neglect to seize this opportunity to achieve some measure of commercial and scientific co-operation?

It is, however, the latter question only and the means by which it may be secured with which the present paper is directly concerned.

The scientific problems of the rubber industry are not, as might be inferred from the preceding remarks, confined solely to the manufacturer of rubber goods.

As in the cotton industry—which during the past year has established a technical committee under the auspices of the Advisory Committee for Scientific and Industrial Research—the problems of the producer, the manufacturer, and the consumer are interdependent and require mutual consideration and co-ordination. To ignore this would be to neglect one explanation for the slow progress made by research in past years.

The manufacturer looks to the rubber grower for adequate, cheap and satisfactory supplies of his principal raw material. Without these he cannot satisfy the demands of the consumer for high quality goods at moderate cost or add fresh items to the already long list of purposes for which rubber has been employed in the services of mankind.

The statistics of the world's rubber supplies are too well known to need recapitulation; thanks to foresight, enterprise, and colonies possessing favourable climates and ample supplies of cheap labour the British Empire has in the course of a few years become the foremost rubber producer of the world. Science, however, has played only a minor rôle in this achievement. The scientific staff at Kew were, in a measure, instrumental in introducing the first *Hevea* seedlings into Ceylon, but subsequently fortune smiled on the young industry and science probably was regarded by the planter more as an enemy plotting his downfall by the synthesis of rubber than as an ally to assist in securing his future prosperity. This distrust has, happily, passed away, and of recent years the assistance of the chemist and the botanist has been sought with a view to improving both the yield and the quality of the product of the estates.

Investigations have been carried out by several agencies working independently, and amongst these may be mentioned the Rubber Growers' Association, the Agricultural Department of the Federated Malay States, and the Imperial Institute, the last named working in conjunction with the Government Agricultural Department of Ceylon. In addition to these British research organisations, a considerable amount of work has been carried out by the Dutch in connection with their plantations in Java.

That much valuable information has already been secured from these efforts is evident from the papers published in various journals and especially in the *Bulletins* issued by both the Imperial Institute and the Agricultural Department of the Federated Malay States, but the scope of the work hitherto undertaken is modest, and the field of research still untouched is wide.

This question recently has been the subject of a paper by one of the foremost authorities on tropical agriculture, and in it an appeal is made for co-ordination of results and increased scientific co-operation.*

These two objects have in a measure been secured for the investigations carried out by the Imperial Institute by the inclusion of some rubber manufacturers on an advisory research committee formed in London.

This co-operation, however, might well be extended to include *all* the agencies responsible for scientific work in connection with the production of cultivated rubber, since the existing resources for research are not such that rivalry or duplication of effort can be considered advantageous, or even of little consequence. The chapter on "Latex" in a well-known standard botanical

* "Present Needs of British Rubber Industry," W. R. Dunstan, *Bull. Imp. Inst.*, XIV., No. 2, p. 592-599.

work on plant physiology refers to "the present imperfect state of our knowledge" and "the need for further experimental research on this subject."*

It must be evident, therefore, that besides the more obvious practical agricultural and technical investigations into questions such as methods of planting, manuring, intercropping, tapping, coagulating, and the like, as well as the eradication of plant, insect, and fungoid pests—all matters incidental to securing a cheap and uniform product—the plant physiologist and the chemist have much to do before we can secure a clear insight into the mode of formation and the functions of the rubber latex in the tree.

The problems of the rubber producer are obviously more botanical and mycological than chemical in character, and consequently can be solved satisfactorily only by investigations carried out in an institution situated in a tropical rubber-growing country.

Such an institution would, however, be of little commercial value if the results of its research work were not made readily accessible and intelligible to those who are directly responsible for the practical management of the estates.

The dissemination of scientific information, however, is always a simple problem compared with that of inducing the public to appreciate and profit by its lessons. Herein, therefore, would seem to exist an opportunity for one of our agricultural colleges at home to render good service to the Empire. The arguments which led to the creation of our Schools of Tropical Medicine surely apply with equal force to the problems connected with the healthy development of useful tropical vegetation. By giving special consideration to the problems of tropical agriculture in its curriculum, such an institution should be able to furnish a supply of suitably educated men to fill the administrative positions on rubber and other plantations in our tropical colonies. Men so trained should be able to appreciate, welcome, and make full use of all the latest developments of agricultural science, and thereby render the work of a tropical institute of agricultural research not only of scientific interest, but also a material factor in promoting the prosperity of the world.

The scientific needs of the rubber manufacturer differ fundamentally from those of the planter. The plantation industry is of recent origin, and its staple consists of one single product obtained by methods and machinery common to every estate. Moreover, individual competition as yet can scarcely be said to exist. Under such conditions co-operation in both scientific and technical research should be a simple matter.

With the manufacture of rubber an entirely different state of affairs exists. The number of manufactured articles of which rubber forms the basis is almost infinite in variety, shape, and size, and the methods of production are correspondingly complicated. Further, keen trade competition exists amongst the various British manufacturers.

The attainment of co-operation in technical research in this trade must, therefore, be beset with many difficulties unless it be preceded by thorough commercial understanding. While an individualistic policy often may be shortsighted, so long as human nature exists in its present imperfect form in general, it must be hopeless to expect a manufacturer from altruistic motives to contribute towards assisting competitors to develop processes in which he, by the expenditure of thought, time, and money, has himself achieved a moderate degree of success.

A suggestion has been made recently by a member of the trade to the effect that an investiga-

tion into the manufacture of solid tyres would meet the approval of rubber manufacturers.* It is, however, very questionable whether their response to a proposal for co-operation to this end would confirm his expectation.

The same individual is credited with expressing the opinion "that academic research on the constitution of rubber would not be supported by the manufacturers."

Here we are faced with a definite statement that purely scientific research has no place in the ideals of the rubber manufacturer. If this correctly expressed the views of the majority of those responsible for the policy of the industry they must certainly have been unconscious of the nature and cause of the developments which have occurred in many other industries during recent years.

In common with other industries the rubber manufacturer requires primarily cheap and uniform raw materials. These must then be elaborated by efficient and economical processes into sound, durable and saleable articles. These obvious wants can be secured only by having a works laboratory to control the uniformity of the raw materials, the efficiency of the processes of manufacture, and the quality of the finished products.

As has already been stated, it is only of recent years that the need for even this limited measure of scientific assistance has received recognition in the rubber trade generally. This, however, is far from exhausting the ways in which science can be of assistance to the manufacturer.

As has been pointed out by Dr. Kenneth Mees, Director of the Research Laboratories of the Eastman Kodak Company,† the manufacturer really requires two other forms of scientific assistance in addition to the works or routine laboratory just mentioned. Over and above this, there should be means for investigating and working out "improvements in products and in processes tending to lessen cost of production and to introduce new products on the market." The solution of the problems incidental to the manufacture of solid rubber tyres would fall into this category.

The routine laboratory should find a place in every works which is worthy of the name, while the second type or technical research laboratory should be well within the means of all the more important companies engaged in the rubber trade. The absence of trade co-operation, therefore, is no excuse in the majority of cases for the neglect of technical industrial research.

These two forms of scientific assistance will necessitate not only a supply of trained scientific men but also scientific data. Satisfactory methods must be available to enable the routine laboratory to carry out the analyses and tests incidental to factory control, while scientific information regarding the chemical and physical properties of the raw material is essential for the solution of many factory difficulties and the development of new processes of manufacture. This brings us to the third description of laboratory postulated by Dr. Mees. His remarks deserve to be quoted verbatim.

"In every case where the effect of research work has been very marked, that work has been directed not towards the superficial processes of industry but towards the fundamental and underlying theory of the subject." This kind of research work involves "a laboratory very different from the usual works laboratory and also investigators of a different type from those employed in a purely industrial laboratory. It means a large, elaborately equipped and heavily staffed laboratory engaged largely on work which for many years will be unremunerative, and which, for a considerable time after its

* Haberlandt, "Physiological Plant Anatomy," 1914, English edn., p. 342, 343.

* Report of the Advisory Committee for Scientific and Industrial Research, 1915-1916, p. 24.

† "Nature," 1916, vol. 97, pp. 411, 431.

foundation, will obtain no results at all which can be applied by the manufacturer."

Herein should lie the road to progress in the rubber industry.

When the contributions to the chemistry of rubber are examined—either in scientific journals or the files of the Patent Office—the names of workers engaged in the trade will be found to be conspicuous by their rarity. Take, for example, the oxidation of rubber, the synthesis of caoutchouc, and the acceleration of vulcanisation, all fundamental questions obviously of more than academic interest. In every instance, the rubber manufacturer generally appears to have been content to occupy the rôle of spectator. He was then unconvinced of the value of pure research. Will the important technical possibilities of the organic accelerator induce him now to modify his views? Should such be the case it will be necessary to consider what means are available to meet and foster this new development of the industry.

There are very few firms in the rubber trade of sufficient magnitude to face lightly the expenditure incidental to a pure research laboratory such as has been described. Joint effort, therefore, would seem to offer the only solution of the difficulty. Co-operation in pure research, moreover, will not present the commercial difficulties which must arise out of joint investigations into technical problems.

Such an arrangement could scarcely assist the inefficient at the expense of the efficient, for the measure of advantage to be obtained from the results of co-operation in pure research must depend on the attention paid to technical research in their respective works by the individual manufacturers.

The existing agencies responsible for carrying out pure research for the benefit of industries would appear to fall into two different classes—Research Institutes, pure and simple, of which a number of examples exist in America,* and to which the recently established Research Department at the Stoke School of Pottery would seem to belong, and the Departments of Technical Chemistry which have been established in connection with certain of our younger Universities. As has already been pointed out, industries require equally both scientific facts and scientific men. The ideal institution for technical research should provide therefore the means to satisfy both those needs. Research organisations unconnected with educational institutions would seem to be exposed to two dangers. In the first place, there is a possibility that they may be regarded by the smaller and less progressive manufacturer as a means to secure an occasional limited amount of technical assistance and to avoid thereby the necessity for permanently employing a chemist in his works.

An institution which had this effect would be inimical to the very objects for which it was designed. Secondly, such an organisation postulates a fairly large permanently appointed staff, the majority of whose members probably will be in receipt of comparatively modest salaries. A tendency will consequently exist for the pick of the junior staff to be attracted to industrial and other posts holding out brighter prospects of advancement, with the inevitable consequence that the intellectual standard of the institution must suffer. As an example of this state of affairs it has been stated that in one year two firms alone acquired the services of no less than nine members of the staff of the U.S. Bureau of Standards.†

A University institution should, in a great measure, be free from these dangers. Moreover, its more independent status should protect it

from having to pander to petty fancies and enquiries of the trade at the expense of more important problems, while a constant stream of post-graduate students should both provide a supply of trained men to fill industrial posts and by the infusion of new views reduce the tendency of the investigations to fall into a rut.

Research in British Universities, however, appears to labour under two serious disadvantages. The first is a tendency to be lavish with bricks and mortar and economical in the technical equipment and salaries of the junior staff. If Universities desire efficiency and whole-hearted service from their staffs they must offer a decent initial salary to attract the most able men, and satisfactory prospects to supply the incentive for subsequent good work. The necessity for adequate remuneration must apply with special force when the department concerned is one of applied research for which the staff must combine both technical experience and scientific ability.

The second danger is that of introducing technical specialisation at too early a stage in the science curriculum. The usual three years' course is little enough time for a student to obtain a grasp of the fundamental principles of his subject, and specialisation can be secured during this period only at the expense of something far more important. A scientific training, however, cannot be said to be complete without some experience of research. The functions of a University are two-fold—it should not only impart but also augment human knowledge. A school of learning which does not foster a spirit of research in all its departments is therefore neglecting one of its most important duties. What more suitable subject for University research can exist than the fundamental problems of some important local industry? Is not the time ripe for a closer general co-operation between our Universities and industries? A limited measure of progress has already been made in connection with such trades as dyes, glass, leather, fuels, and metallurgy, but this is far from exhausting the list of important industries and Universities of repute. Were some University to express its willingness to establish a post-graduate department of research to be devoted to the chemistry of rubber, its enterprise would deserve to command the support of all connected with the trade. Granted an organisation similar to the Mellon Institute of the University of Pittsburgh* but limited in scope to one industry, possessing an efficient and adequate staff free from the distractions of elementary teaching, there could scarcely fail to result a school of specialised research, valuable alike to education and to industry.

A systematic investigation into the methods for the analysis of rubber goods would earn the gratitude of every chemist who has had any experience of the procedure at present in vogue, and of the difficulties which so frequently arise in the interpretation of the results. The methods for determining the physical qualities of ebonite furnish another promising field for useful work. The importance of this question may be judged by the fact that it at present forms the subject of an enquiry by a technical committee of the Institution of Electrical Engineers.‡

This should suffice to show the important though difficult and perhaps prosaic physical and analytical research which calls for immediate attention. Of the more fundamental problems which confront the rubber manufacturer that of vulcanisation undoubtedly must be given precedence.

The explanation of the remarkable modification in physical properties produced by heating rubber with sulphur, and of the catalytic effect of litharge and certain other substances in accelerating this

* Research Institutions in the United States—"Nature," 1917, vol. 99, p. 271.

† "Nature," 1917, vol. 99, p. 275.

‡ This Journal, 1916, p. 18.

action may possibly be found by direct investigation. It is probable, however, that investigations into the constitution of rubber, by both analytical and synthetic methods, may contribute materially to the solution desired.

What has been said should be ample to indicate the scientific needs of the rubber industry and some of the problems which await solution.

It remains for those interested in the prosperity of the rubber trade—whether they be planters, manufacturers, or users—to consider the future and co-operate in generously supporting any scheme which promises to promote the well-being of an industry which since its earliest days has been largely identified with the English-speaking race.

DISCUSSION.

Dr. TWISS said that Mr. Porritt laid a considerable proportion of blame for the lack of research in rubber on the manufacturers, and he hardly thought that all this blame was deserved. The manufacturer had little sympathetic regard for the constitution of rubber. The least important point in the practical side of rubber chemistry was the constitutional formula. Manufacturers had had a great deal of research done on the subject of rubber, but from mistaken reasons they were not allowing it to be published, and a great deal of information was locked up inside the various factories. Another point which had not encouraged the manufacturer was that the investigations which had been made were very often so disconnected. Mr. Porritt appeared to expect that the recent discovery of accelerators would prompt the manufacturers to take up academic research, but so far the papers which had been published on accelerators had been, generally speaking, crude and disconnected. It had been more a matter of testing, missing 59 times, and the 60th time happening to find an accelerator—not a genuine method of scientifically organised research. He thought Mr. Porritt's comparison of rubber with esters of cellulose was not altogether happy. There was a much greater excuse for the rubber industry not having raised its pure chemistry to a higher stage than would appear at a casual glance.

Dr. STEVENS said that rather than enter into a discussion in regard to the manufacturers' responsibility for research in the past, they should look to the future. There was now a Rubber Manufacturers' Association, comprising some of the largest firms all over the country. Now was the time for the manufacturers, through their Association, to make arrangements to start research which would be of value to the industry, or at any rate to the subscribing companies. Of course, any research of that sort in the beginning must be on almost purely theoretical lines; it was no use starting with a set of physical experiments.

Mr. SPROXTON said that Mr. Porritt had compared the cellulose esters industry favourably with the rubber industry in the matter of research, and he was pleased to hear this; but at the same time he thought their knowledge of the physical state of the cellulose esters was not quite so profound as the ponderous nature of some of the literature would lead the casual reader to believe. There was a considerable similarity between the problems in the rubber industry and those in the cellulose esters industry. It was necessary to co-ordinate the results of laboratory tests with the durability and commercial value of the final material, and that was a most difficult problem. Some such connection was supposed to exist in the rubber industry, and it was certainly the case in the cellulose esters industry. It was possible to get a sort of pseudo-toughness in plastic materials made from the cellulose esters which would mislead the ordinary observer to believe they

were just as durable as a really properly made cellulose ester plastic, and yet they were not so; they were derived from solutions of very low viscosity. Probably the same trouble arose in the rubber industry. Where a company could afford to keep a fairly numerous staff it would pay not only to employ chemists but physicists, because after the initial chemical processes were finished, in the rubber industry as well as in the cellulose ester industry, the study of the problem became almost entirely physical, and for that reason the physicist ought to find full scope for his energy and his knowledge in the factory.

Mr. F. H. ALCOCK asked the author to reconsider whether his definition of a University was a sound one. If so, it certainly was not his own idea of what a University should be.

The PRESIDENT agreed that the sting of the paper had been taken out by the one read previously, which told them that there were at any rate some manufacturers who were far-seeing and understood the value of scientific investigation, and what was more important still, allowed the results of these investigations to be brought under the notice of the industry generally. He agreed with what had been said as to the employment of physicists, and was pleased to say that he had got chemist and physicist to work together. The combination was extremely valuable, and both admitted it, especially the chemist.

Mr. PORRITT, in reply, thought Dr. Twiss and himself were in agreement in the main, although the form the institute was to take was a debatable matter. Whether technical research in the fundamental questions of technology should be carried out at the University was also debatable, though he could not see himself why it should not be satisfactorily done. He happened to be acquainted with both the rubber industry and the cellulose esters industry, and with regard to their scientific difficulties there was a considerable analogy. Mr. Sproxtton had referred to the literature being unsatisfactory. The literature on the subject of rubber and the subject of cellulose was very similar; contradictory statements abounded in both, and it was extremely difficult to find the truth.

GROUP II.

Prof. HENRY LOUIS in the Chair.

THE LOCAL METALLURGICAL INDUSTRIES.

BY PROF. T. TURNER, M.Sc.

Work in the Metallurgical Department of the University of Birmingham, in the new buildings at Edgbaston, has been suspended, these buildings having been converted into the 1st Southern General Hospital. University classes are conducted in the lecture rooms and laboratories of the Technical School. As the numbers in attendance are smaller than usual, the accommodation is ample; and there has been no interruption in the work, except such as is due to a depleted staff, and the employment, on national service, of practically the whole of the British-born students of military age. But it is not merely instruction and research which have been interfered with by the war; the energies of the whole district have been diverted and intensified, and changes have been introduced, the results of which will be seen in later years. The population of which Birmingham is the business centre is nearly equal to that of half Belgium; and the staple industries such as coal, iron, steel, copper, brass, aluminium, refractories, and engineering in many branches are all such as contribute to the national wealth in days of peace, and to the national strength in days of war. As General Groener, the Head of the German War Department, recently said: "The

whole of what is produced for fighting purposes may be likened to a pyramid, and the base of that pyramid is coal and iron." Closely associated with the production of coal and iron in this district we have the supply of refractories, and the manufacture of copper, brass, nickel, aluminium, and other metallurgical materials.

The production of iron and steel in the Staffordshire district is limited by the moderate supplies of ore in an inland centre. The output is, however, by no means negligible, and is equal to that of the whole of the United Kingdom a century ago. The basic process of steel manufacture is that which is chiefly followed, and the open-hearth furnace is taking the leading place here, as in other centres of the steel trade. The wrought iron trade, though much smaller in volume than in its palmy days, still flourishes, and all the local works have been fully employed at remunerative prices. The blast furnaces produce foundry forge and basic pig irons: the maximum output has been maintained, and it is proposed to put additional furnaces in blast.

In the brass and copper industries there has been unprecedented activity. Though no new scientific discoveries have to be recorded, many improvements have been introduced into works practice. Incidentally reference may be made to the extended use of town gas for melting purposes, with resulting increase of speed and economy. Tilting furnaces are now much more used than was formerly the case. An important local industry is that of cartridge manufacture. The results of researches conducted in the University of Birmingham, by Dr. O. F. Hudson, have been found of considerable value to local manufacturers, particularly in connection with the annealing of metals, and the composition and treatment of certain brasses which have recently had an extended application.

The local nickel industry has been taxed to its utmost capacity; not only has there been the unprecedented demand for cupro-nickel, but the nickel silver trade has been by no means idle, while there has been a demand for pure nickel goods such as were formerly imported from the Continent. An important enquiry as to the world's sources of supply of nickel has been conducted by a Commission appointed by the Canadian Government. Of this Commission, Mr. G. T. Holloway acted as chairman. The Committee visited Birmingham during the course of its inquiries; and the report which just has been issued is, and will long remain, a most valuable standard of reference in relation to the occurrence, extraction, and uses of nickel.

In no direction has there been greater expansion than in the aluminium industry. There are now several large aluminium foundries in the city, and the output of only one of these would be equal to that of the whole world a dozen years ago. The product has been largely used in connection with munitions of war, as in certain parts of shells; in aeroplane construction, and for many other purposes where strength and lightness are desired. The metal is now very generally melted by means of town gas as fuel. This has been found to be cheap, clean, and convenient. Melting is performed either in graphite crucibles, or very commonly in cast iron pots, which are preferably protected by a wash of inert material. Pure aluminium is very seldom used; the alloying metals include zinc, copper, and occasionally tin, nickel, manganese, or other metals. Researches in the properties of these alloys have been conducted, and so far as opportunities permit, are still in progress in the University laboratories.

Recently special attention has been drawn to the production of malleable cast iron, which is an industry which has long been associated with

Walsall, Birmingham, and the intermediate district. There are at present some 90 firms engaged in the local trade, and many of these conduct their business on a relatively small scale. The process generally followed is the Réaumur, or European method, of more or less complete oxidation of the carbon, as contrasted with the American or "Black Heart" process in which the carbon is precipitated as fine grained, or secondary, graphite. For the production of this malleable cast iron the raw material employed is obtained from pure hematite ores, as it is usually considered to be important to have metal which is low in phosphorus and manganese. The demand for specially pure ores for other purposes has led to attention being directed to the question as to how far other materials can be employed to replace the purer cast iron hitherto used. It is known that good material can be produced even when 0.25% of sulphur or phosphorus is present, though the details of the annealing process have to be modified somewhat to suit the kind of iron employed. The problem is how to introduce an iron of a somewhat different composition without disorganising the work of the smaller manufacturers who depend largely upon old-established methods of working. No doubt in time the larger firms will be forced in this, as in other manufactures, to adopt scientific methods, including chemical analysis and accurate temperature measurement. If this should be the result of the present difficulties the whole industry will benefit permanently. It is generally recognised that the trade is an important one; that it is capable of very considerable extension; and that it is upon the adoption of scientific methods that such extension (or extinction) will ultimately depend.

CARTRIDGE BRASS.

BY H. W. BROWNSDON M.Sc., Ph.D.

The term cartridge brass includes pure copper-zinc alloys containing 65 to 75% of copper. Such alloys are specially adapted for the manufacture of cartridge cases where the properties of malleability, ductility, and strength require to be combined in such a manner as to facilitate working, and at the same time to produce a finished product which will withstand the shock of firing in rifle or gun.

In order to meet these conditions, the raw materials used, viz. copper and spelter, must be of the highest quality and purity. The copper should be equal to electrolytically refined, and practically free from lead, iron, bismuth, arsenic, antimony, etc., and should on analysis show 99.93 to 99.95% copper. It is desirable to melt down cathode copper into ingots before use in the manufacture of cartridge brass. The spelter should analyse 99.9 to 99.95% of zinc and be as free as possible from lead, iron, arsenic, etc.

The two metals, together with a proportion of clean heavy scrap, are melted in crucibles, the molten metals thoroughly mixed and then poured into dressed cast iron ingot moulds.

A good cartridge brass should not show on analysis more than Fe 0.045%, Pb 0.025%, with traces of other constituents.

The cast metal is by subsequent rolling and intermediate annealing reduced to a definite thickness, in which form it is termed finished strip.

The changes in physical properties that the metal undergoes in passing from the ingot to the finished strip are shown by the following figures:—

	Yield point.	Tensile strength.	Elonga- tion.	Hardness, Brinell.
	tons.	tons.	%	
ingot (chill cast)	6	16	60-70	60
strip, hard rolled	over 20	30-40	10-15	150-200
finishing strip, annealed at 650°C.	6	20-23	65-75	60

The annealing operations in the manufacture of cartridge brass are carried out at temperatures in the neighbourhood of 650° C. It is not uncommon practice to work at a higher temperature than this, say, 680° to 700° C when annealing the metal in the thicker and heavier stages. By so doing, the time required for annealing is reduced. With thinner metal and products which more rapidly attain to the furnace temperature the 650° C. temperature is more closely observed, the time required being determined by the form of the product to be annealed and by the type of furnace used for the annealing. In muffle furnaces worked intermittently, the time may be $\frac{3}{4}$ hour, whilst in rotary worm-fed gas muffles, suitable for small articles, the time may not exceed 5 minutes.

Apart from the enormously increased demand during the past three years, there has been no development of interest. Output has largely dominated other considerations.

Firms already engaged in the manufacture before the war have increased their plant and developed the manufacture on pre-war lines. Other firms who have been pressed into the service of the nation have followed more or less in the footsteps of those already acquainted with the details of manufacture. The lessons to be gained, however, from the widened experience that this increased output has demanded are not few, and many details are open to be improved upon when conditions permit. In all manufacture which calls for the repeated cold working of copper alloys and the necessary alternating intermediate annealings, homogeneity and uniformity of the finished product is the chief aim, and at the same time one of the most difficult to achieve. The conditions requiring close attention are:—

- (1) The chemical composition of the alloy.
- (2) The casting of the molten alloy.
- (3) The work to which the alloy is submitted during the mechanical operations.
- (4) The annealing of the alloy between the mechanical operations.

The uniformity of the finished product may therefore be influenced at a number of stages in its manufacture, and the best final result can only be obtained by exercising scientific control and intelligent supervision at all the different stages of manufacture. The obtaining of uniform mechanical working offers little or no difficulties. The same cannot be said of the annealing between the mechanical operations. Whilst the conditions and best temperatures for carrying out the annealing are thoroughly understood, the difficulties that arise due to the handling of bulk and to the necessity of rapid production are considerable.

What may be recognised as a theoretically best method, may in practice prove too slow. Since there are several annealing operations from start to finish, even when these are individually known to vary more than desirable, an average final product may be arrived at which gives satisfaction.

Wrapped up closely with annealing is the hardness of the metal, and for carrying out this work in a satisfactory manner, the pyrometer, the microscope, and the hardness testing machine must be applied.

Another important factor militating against the uniform successful manufacture, is the difficulty of finding labour with the intelligence and

conscientious application so necessary for conducting the operations in a completely satisfactory manner.

It has been difficult during the past years of intensive manufacture to pay the necessary attention to the economical side of the manufacture. From raw material to finished product in the case of cartridge brasses, the percentage loss of material through volatilisation, oxidation, and pickling amounts to several per cent. Some of this is recoverable and during the annealing process to some extent preventable. The chief improvement to be looked for in this direction is annealing in a non-oxidising atmosphere. There is nothing new in the idea of preventing oxidation losses during annealing, but as in numerous other matters, the war has impressed upon us the shortcomings of many pre-war methods.

With the withdrawal of sulphuric acid from use for pickling purposes, and its substitution by nitre cake solutions, the value of clean annealing as against dirty annealing, has become much more emphasized, and in the future the bright annealing of all copper alloys should be aimed at.

Whilst there appear to be no great revolutionary improvements of a scientific nature ahead of us in this industry, there is no doubt that modifications of an economic nature are possible.

The manufacturer finds no difficulty in obtaining metal of the purity demanded. In the details of working, the metallurgist knows exactly what he wants both as regards annealing temperatures and work that can be put on the metal. His difficulty is in securing that uniformity of treatment which ensures complete success.

Pyrometry is an essential aid, but its application to this class of work in bulk is still open to considerable improvement. The testing of the hardness of the products during manufacture and when completed is a matter of importance, and the method to be employed is best determined by the nature of the product to be examined. Both the scleroscope and the Brinell instrument are of value, and it is a matter of detail as to which is the more suitable. The fundamental conditions involved in the manufacture are the alternating production of strains by work, and their release by annealing. The final product is commonly left in a more or less strained condition. As a means of determining the position and nature of the strains, the weakening of the metal by immersion in mercuric chloride solution, which allows the strains to develop visible cracks, is most valuable.

The success of the industry, therefore, lies in carrying out the manufacture under uniform conditions, which conditions should be governed by:

- (1) Analytical control of the metals going into the pot.
- (2) Analysis of the cast ingot.
- (3) Correct distribution of mechanical work at the various stages of manufacture.
- (4) Correct annealing checked by pyrometer, microscope, and hardness tests.

Finally, a complete examination, both chemical, metallurgical, and physical, of the finished product should be systematically made.

Of the metal worker's art, there are few examples more interesting than a brass cartridge case. The chemist has to see that the copper and spelter conform to rigid specifications before they go to the pot. The caster has carefully to apply all the details of his art (only gained by experience) to the production of a sound ingot. The roller in the mill rolls the ingot down until further work is undesirable without first removing strains and softening by means of annealing. The annealing, though helped by pyrometry, is still largely a matter demanding experience and sound judgment. Towards the end of the rolling operations, mechan-

cal precision is required to produce finished strip of uniform thickness to within 0.001 in.

During passage through the mill a keen eye of inspection is required to prevent faulty work passing through—local flaws have to be removed and any work showing defects out of the common put on one side for more expert examination and decision as to its further use.

From the strip to the cartridge case the engineer and the metallurgist have to work closely together, the former to design and produce the tools and machines which will work the metal stage by stage to the desired finished form, and the latter has to see that the metal is in no operation overstrained and that between operations strains are sufficiently removed by correct annealing conditions.

Of subtle, not thoroughly understood difficulties there are none. Success lies with a never flagging close attention to detail and continual intelligent application of scientific control.

The interest that the ammunition manufacturer takes in cartridge brass does not cease with the production of the finished cartridge case, for of the components of a cartridge the case alone is left undestroyed, the propellant and the shell or bullet being completely destroyed so far as further useful recovery is concerned.

Cases other than small arms may, if not seriously mechanically damaged, be re-formed to size and used again. Small arms cases, however, after once being fired, suffer a deterioration which not only prevents them from being used a second time, but which also prevents them from being utilised as scrap for casting cartridge brass.

The causes of this deterioration are metallic mercury and antimony salts, products from the explosion of the ingredients of the percussion cap. A portion of these products is retained on the interior surface of the case. From the point of view of re-using the case as a case, it is the weakening effect off the mercury on the strength of the brass that gives the trouble. From the point of view of using the fired cases as scrap for re-melting, it is the antimony which is the bngbear. Much may be done by washing the fired cases in suitable solutions, but even after repeated treatment in this way, when put into a heat for best cartridge metal, antimony will be found in harmful quantities in the ingot.

The economical utilisation of scrap forms such an integral part of the brass maker's business, that this question of the use of fired small arms cases as scrap under present conditions is one of considerable magnitude when the demand for cartridge brass of high purity is predominant.

The industry must, after the war, be of much diminished volume. For high quality cartridge brass there will always be a demand, and apart from quality, economical production will be the dominating factor in success or otherwise.

For permission to make this communication I have pleasure in expressing my thanks to the King's Norton Metal Co., Ltd. To Mr. R. A. Ernest Payne, the Company's General Manager, I am deeply indebted for much helpful criticism. For valuable suggestions and data my thanks are also due to Mr. H. Rogers, Works Manager.

DISCUSSION.

Mr. ALEX. E. TUCKER said that the heat at which the strips were cast was most important. Were they cast as hot as possible? Then, again, in regard to the manufacture of fine tube the author was emphatic on the point that he received virgin metals of a high grade, but he (the speaker) had often found that copper banding used on cartridges contained a quantity of arsenic. He agreed as to the value of the mercuric chloride test.

Mr. F. JOHNSON asked as to the percentage of lead in cartridge brass.

Mr. H. L. HEATHCOTE said he was glad to see some figures as to the tensile strength of cartridge metal. It was a disadvantage if the yield-point exceeded seven tons to the square inch. If it was greater it would lead to flaws extending. For testing the hardness of finished munitions they had devised a pair of pliers in one leg of which the cartridge case was placed. The other leg carried a cylinder and a spring, and by closing the pliers the indentation gave an index as to the hardness of the metal.

Dr. BROWNSDON, in replying to Mr. Tucker, said they worked at the lowest pressure possible right through. It was not unusual to find traces of arsenic in certain kinds of copper. The amount of lead that could be present in a cartridge case was as high as 40%; by that he meant that a case with 40% of lead would fire satisfactorily, but it spoiled easily in the annealing. Then again, if they were stored they might split in the mouth. The purer they were the better. He had been able to trace trouble in cartridge brass to phosphorus. It arose from the scrap metal, and it tended to cause metal to crack when in a strained condition. If it was put in for de-oxidising purposes it should be got rid of as quickly as possible. In regard to the percentage of antimony the quantity was small, probably 0.06 or 0.07%. Mr. Heathcote's tests were valuable, and the colour methods of pyrometry were also good. Much remained to be done in the latter direction, and that method had a great future.

ON THE SUPERHEATING OF SLAGS AND METALS DURING REFINING, SMELTING, AND ALLOYING OPERATIONS.

BY J. E. FLETCHER, M.I.MECH.E.

1. In the production of wrought iron and steel or ingot iron in the open hearth furnace, it is becoming clearer that the mechanism of refining and alloying is that of the intimate reactions which occur between the various constituents of the pig iron, ore, and scrap charged and those of the slags used in the efficient carrying out of such processes.

The finished cold cast products are crystalline composite masses made up of more or less carbonized or otherwise alloyed crystals separated from each other by boundaries which probably always contain minute particles or films of isolating matter. It is known that such films often contain the iron oxides FeO and Fe_2O_3 together with silicates of iron and manganese. There is further evidence that occluded gases in a fine state of division occur within the crystal boundaries. Such films must tend towards the non-welding of the adjacent crystal faces when the molten or liquid-plastic crystals are being drawn together in their passage to the solid state.

The high temperatures needed in the ferrous alloy processes make the study of the reactions and of the constitutional changes in both slags and alloys exceedingly difficult; there is a sense, however, in which it may be said that the reactions at high temperatures are more simple than at lower ones. Thus M. Charpy succeeded in cementing or carbonizing iron filings by heating at 650°C . for about forty hours in potassium cyanide, the alloy produced being the iron carbon eutectic containing 1.3% carbon and melting at about 1130° to 1135°C . Similarly after heating for 85 hours the alloy containing 6.67% carbon and 93.33% iron (Fe_3C) was produced. With only three hours' heating at 1130°C . the 4.3% carbon eutectic alloy resulted. Moissan, at the temperature of the electric arc, succeeded in carbonizing iron to a content of about 4% in three minutes, and the author, in a like period, also at the temperature of the electric arc, obtained an alloy containing 5.5% carbon. Later Ruff and Goecke

produced a 9.6% carbon iron alloy by cementation in an electric furnace at 2220° C., the time required at this high temperature being relatively short. These experimenters concluded that there is a progressive formation of the carbides Fe₃C, Fe₂C, and FeC, at increasing temperatures until at about 2700° C. gasification of the alloy (FeC+Fe) takes place.

II. The refining and alloying slags in iron and steel processes may be divided into three types. Those having temperatures of formation, fusion, and equilibrium (1st) higher, (2nd) approximately the same, and (3rd) lower than the fusion and equilibrium temperatures of the metallic alloys in contact with the slags.

FIG. 1.

The slags of type (1) are representative of blast furnace working, where the pig iron fusion temperatures are in the neighbourhood of 1140° C. Such slags have the composition:
CaO+MgO+FeO+MnO=50 to 55 per cent.,
SiO₂+Al₂O₃+P₂O₅=45 to 50 per cent.,
the fusion temperatures of which are in the region of 1400° C.

The slags of type (2) are typical of the puddling process where the fusion and softening temperatures of the metal being operated upon vary from 1130° to 1450° C., the slags having fusion temperatures varying between 1080° C. and 1350° C. and being silicates of iron and manganese of the approximate analysis:
FeO+Fe₂O₃+MnO=70 to 80%. SiO₂=20 to 30%.

The slags of type (3) are representative of the open hearth steel melting processes. Here the metal fusion temperatures vary from 1130° to 1500° C. whilst the slags fuse between 1100° C. and 1350° C. and have the typical analyses:
CaO+MgO+FeO+MnO=40 to 50% (acid process).
SiO₂+Al₂O₃=50 to 60% (acid process).
CaO+MgO+FeO+MnO=80 to 70% (basic process).
SiO₂+P₂O₅=20 to 30% (basic process).

III. Now obviously the temperatures of refining, smelting, and alloying chambers or hearths of the furnaces being operated must be kept higher than those of the slags or metals under treatment. Hence in case (1) the blast furnace metal is superheated above its fusion point; in (2) the puddled iron and slags may be kept nearly at their proper fusion temperatures, and in (3) the slags are superheated above their fusion temperatures.

Taking as concrete examples the cases cited:
(1) *Blast furnace slags.*—Here the slag fusion temperature is higher than that of the contact metal. The temperatures of the tuyère zone are in the region of 1500° C., the slag fusion temperatures being between 1350° C. and 1450° C., whilst the underlying metal is melted at roughly 1140° C. The slag and metal are therefore continuously superheated above their fusion temperatures. The metal in the hearth is primarily of eutectic composition or thereabouts, viz., 4.3% carbon and 95.7% iron.

The result of superheating this eutectic is first to render the contained carbide of iron, Fe₃C, unstable. The higher it is heated above its melting point, 1130° to 1135° C., the greater is this instability apparent and its sensitiveness to refining or alloying action increased. Similarly the oxide constituents of the slag which are reducible at the hearth temperature become unstable under conditions of superheat, the silica, SiO₂, and phosphate of lime, 4CaO.P₂O₅ being readily reducible.

At the hearth temperature, 1500° to 1600° C., the slag tends to adjust its composition by parting with SiO₂ and P₂O₅ until it attains equilibrium consistent with the degree of superheat. If given sufficient time at, say, 1500° C., an equilibrium corresponding to the slag composition 20% Al₂O₃, 80% CaO, MgO would arrive in the case of a smelting using a working slag of primary non-superheated analysis 30% SiO₂, 15% Al₂O₃, 55% CaO, MgO. The 1500° C. saturated slag would then be inert, there being no further reducible constituent present in the slag. The metal in contact with the slag would also have moved towards stable equilibrium and it can be shown that in the case of ferro silicon manufacture an alloy of composition C 0.5%, Si 9.3%, Fe 90.2% would result when the slag becomes inert. The fusion temperature of resulting slag and metal would be about 1450° C. (In this case phosphorus, sulphur, and manganese have been omitted for the sake of simplicity.)

It is impossible at present to state the composition which corresponds to the stable equilibria of slags at varying temperatures or of the metallic alloys in contact therewith, but it may be inferred from the foregoing that by proper adjustment of the primary slag composition it is possible by correct temperature control to regulate the alloying actions in the metal.

It is clear that the cast iron becomes alloyed with silicon and phosphorus at the expense of its carbon the more readily as the slag is superheated and hence free to act on a superheated metal (unstable) in contact with it. Fig. 1 illustrates the changes in the composition and temperature of equilibrium during the progressive alloying of a white iron with silicon. The active and relatively inert conditions of the slag are indicated by the shaded area marked "superheat." The higher the superheat the more active the slag and the more unstable the metalloid compounds in the metal attacked.

FIG. 2.

There are, doubtless, cases where, as in certain pneumatic refining and smelting processes, the excess of oxygen leads to oxidation of the metal underlying the slag. Such oxides may there rise to the surface and enter the slag which under certain temperature conditions may become more active, increasing the slag superheat because of the addition of iron oxide to the slag and coincidently lowering its fusion point. Carbon in a pig iron charge may thus be oxidised at the expense of iron oxides FeO, Fe₂O₃ in the slag, iron passing back into the metal; such action is coincident

with or preceding the silicon or phosphorus transfer. Thus a blast furnace slag may become rich in FeO, the resulting pig iron being white. Iron has then been reduced from the slag in preference to silicon and the total carbon content of the pig iron is lower than in the case where a normal slag free from FeO has been employed.

Puddling slags. In the puddling process the slags are of the type $(\text{FeO}, \text{Fe}_2\text{O}_3, \text{SiO}_2)$ having temperatures of fusion and equilibrium not much different from those of the pig irons which it is desired to refine. Here it is necessary to desilicise, dephosphorise and decarburise the pig iron underlying or in contact with the slag. The initial fusion temperature of the pig iron to be refined is about 1110° C., that of the first superposed slag being, say, 1260° C. This slag is therefore superheated and consequently active. Unlike the blast furnace slag the puddling slag is basic and continues so throughout the process. There is no deterrent or inert constituent such as lime or alumina, hence temperature variations rapidly alter the slag constituents. The active iron oxides in the slag attack the unstable iron phosphide and silicide in the pig iron and primarily furnish the oxide for gasifying the unstable carbon in the superheated iron carbon alloy and for oxidising the silicon and phosphorus which are also but feebly stable at temperatures above 1100° C. There is an automatic adjustment of the slag composition throughout the process. At the beginning and end of the operation the temperatures are higher than during the intermediate stage. The initial and final slags are therefore high in $\text{FeO}, \text{Fe}_2\text{O}_3$ and low in SiO_2 , whereas in the intermediate stage the slag is more silicious and more readily fusible. During "rash" or careless working the end of the operation is conducted at too high a temperature hence the slag is too highly superheated and adjusts its composition by robbing the iron bath or sponge. The iron oxide thus added to the slag is largely the result of oxidation by the furnace gases (rich in O and CO_2). Fig. 2 illustrates the foregoing actions. It is seen that the superheat is not so great as in the blast furnace operation. Fig. 3 shows the

FIG. 3.

progress of refining and the coincident adjustment of slag composition during the complete puddling process and illustrates most clearly the effect of superheat on the slag and metal equilibria.

IV. (A) In the production of certain alloy steels the effect of superheating the working slags

results in the pronounced separation of the most readily reduced slag constituent. Thus in the making of manganese steel in the open hearth furnace the primary slag covering the molten pig iron charge was a rich ferrous slag of the composition approximately $\text{FeO}, \text{Fe}_2\text{O}_3 = 80\%$, $\text{SiO}_2 = 20\%$, fusible at about 1300° C. Into this a pyrolusite ore of analysis $\text{MnO}_2 = 85\%$, $\text{CaO}, \text{MgO} = 5\%$, $\text{SiO}_2 = 10\%$, was gradually added. The MnO_2 becomes MnO on superheating, the FeO being changed to Fe_2O_3 by the O liberated from the MnO_2 . It was then found that the FeO and Fe_2O_3 in the slag, if increased by further additions of hematite ore (Fe_2O_3) and lime caused a rapid reduction of the Mn from the slag, Mn entering the liquid metal. When the

FIG. 4.

slag contained over 50% of Mn then manganese entered the metal whereas if the slag was adjusted so as to contain above 50% of Fe, then iron was reduced from the slag in preference to manganese. An increase in the superheat in either case increased the rapidity of the reduction. The temperature was not measured but it was noticed that the higher MnO slags were more fluid than the rich FeO slags and were apparently fusible at a lower temperature. Hence at the practically constant furnace temperature the high MnO slags were more highly superheated than the high FeO slags, hence more unstable and the Mn in consequence more readily reduced.

(B) The refining of alloys may be illustrated in the case of the elimination of manganese in the puddling or open hearth steel processes. Thus the reaction between the slag constituent FeO, Fe_2O_3 and the alloy constituent Mn_3C in the pig iron is of the type:

Manganous oxide displaces the iron oxides in the slag, the manganese in the pig iron being replaced by pure iron from the reduction of the iron oxides. Superheating the slag renders the $\text{FeO}, \text{Fe}_2\text{O}_3$ more active whilst superheating the molten pig iron increases the instability of the Mn_3C . In the interaction CO gas is liberated. The slag is enriched by the entrance of MnO at the cost of the iron oxides $\text{FeO}, \text{Fe}_2\text{O}_3$. Professor Turner's view that in such actions the active oxides $\text{FeO}, \text{Fe}_2\text{O}_3$ are the reducing agents has been taken. They are in the state of least stability and hence in the condition to react with the other unstable compounds present when by superheat their stability is decreased. Possibly at the moment of exchange it is the ferrous oxide which reacts with the Mn_3C in a reversible sense thus: $-3\text{FeO} + \text{Mn}_3\text{C} \rightleftharpoons 3\text{MnO} + \text{Fe}_3\text{C}$.

Superheating the oxide FeO in an oxidising atmosphere leads to the formation of Fe_2O_3 (as in the production of "Bull dog slag" by calcining

puddling furnace tap cinder). On the other hand liquid Fe_2O_3 when in contact with molten Fe alloys is readily converted to FeO provided a reducing or neutral atmosphere is maintained in the working chamber.

Alloying a metallic mass underlying a rich slag. In silicising the white eutectic iron in the hearth of the blast furnace the SiO_2 in the slag interacts with the Fe_3C in the carburised white iron in a reaction of the type:

The carbide of iron in the eutectic metal is displaced by silicide of iron and pure iron is coincidentally set free. CO gas is liberated and the slag is impoverished by the loss of the silica SiO_2 . This exchange is affected by the superheating of the slag, the silicate of lime or magnesia therein becoming unstable. The interaction between the SiO_2 and the unstable superheated Fe_3C is thereby promoted as shown.

(c) *Liberation of occluded gases.* When cast iron is heated considerably above its melting point the occluded gases, which are not inconsiderable in quantity and consist mainly of CO and H, are set free. An examination of the microstructure of a pig iron which has been thus heated towards its boiling point reveals particles of silica surrounded by an envelope of ferrite together with flakes of coarse graphite. It would appear that a reaction has taken place in this case between the escaping CO gas and the silicide of iron Fe_2Si thus:

The slaggy particles appearing in the microstructure are probably a silicate of iron formed as per the reaction:

In some cases such silicate slag rises to the surface of the metal which has been desilicised to some extent by gaseous means. Again, sometimes iron oxide particles occur mechanically mixed and distributed throughout the cast iron or steel mass as a result of over-oxidation or over-blowing in the hearth or bath of the furnace or converter. The effect of superheating such an alloy is further to refine the metal thus:

H. Brearley has illustrated this action in his book on case-hardening, where a slag globule is shown surrounded by a ferrite envelope, and generally in iron and steel, slag streaks are associated with adjacent ferrite.

V. The mechanism of refining and alloying through the offices of the slags is shown in the tables Nos. 1 and 2. In the blast furnace a portion of the carbon in the carbide, Fe_3C , is liberated in the CO gas formed and pure iron is freed to unite with the Si and P as silicide of iron, Fe_2Si , and phosphide of iron, Fe_3P . These actions occur when the slag is superheated.

The automatic adjustment of a typical blast furnace slag is shown in Fig. 4, where, during the alloying of the iron in the blast furnace hearth with silicon (the resulting pig irons having 0 to 3.0% silicon), the slag composition alters thus:—

	SiO_2 .	Al_2O_3 .	$\text{CaO},$ $\text{MgO}.$	Slag softening temp.
	%	%	%	°C.
Before alloying with Si	23.5	20.7	47.1	1435
With 1% Si in pig iron	23.1	21.5	48.9	1440
With 2% Si in pig iron	27.5	21.7	49.7	1440
With 3% Si in pig iron	26.5	22.2	50.3	1445

As the slag adjusts itself during the loss of Si the fusion temperature of the slag is raised. Hence a higher hearth temperature and resulting

slag and metal superheat become necessary as the more highly silicious pig irons are made.

Table 2 illustrates the mechanism of refining action in cupola, open hearth, and puddling operations. Here the pig iron being refined is superheated above its melting point, and the silicide, phosphide, and carbide of iron being thereby rendered unstable react with the similarly unstable slag oxides (in this case the iron oxides). Silica and phosphoric acid escape to the slag and CO gas is liberated. The iron set free by the decomposition of the silicide, phosphide, and carbide of iron and that added by deposition from the slag oxides, together with the primary iron crystals in the original pig iron (if containing less than 4.3% carbon) yield a refined product more or less free from silicon, phosphorus, manganese, and carbon.

VI. It is evident from the foregoing that intimate contact between the metal and the slags in smelting, refining, and alloying operations are imperative if successful results are to follow.

In the blast furnace the reduction of the ores must be largely through gaseous (CO) influence. It is not possible for sufficiently uniform carbon (coke) contact with the oxide of iron (Fe_2O_3 , etc.) particles to take place. The slag blanket which covers the metal in the hearth of the furnace is agitated by the splashing and penetration of the drops of liquid metal and slag as they descend from the upper portions of the tuyère zone. Hence there is a greater contact between slag and liquid metal than at first appears. The relationship between the area of slag contact and the iron smelted per hour is of practical importance. The

ratio: $\frac{\text{area of slag contact (sq. ft.)}}{\text{iron smelted per hour (tons)}}$ is, in the case of modern hot blast furnaces 15 to 25. In the days of cold blast furnaces the ratio was as high as 40 sq. ft. of slag contact per ton of iron smelted per hour.

In the foundry cupola the ratio for modern furnaces is 0.7 to 1.0 sq. ft. per ton of iron melted per hour, and in the open hearth steel melting furnace the ratio: $\frac{\text{area of slag contact}}{\text{metal refined per hour}}$ is 20 to 30. In modern rapid practice in large furnaces the ratio is tending to increase, shallow baths and large area of slag contact being necessary for intensive outputs.

The more viscous and light the slag, the greater is the need for large contact area. During mechanical or natural agitation the heavier slags penetrate the metal surface in direct proportion to their density. In the heavy yet mobile puddling slags the rapidity of the refining action is readily explainable and the low viscosity combined with the continuous hand or mechanical rabbling promotes better contact between the metal and oxide particles.

It can be shown that in the alloying of silicon with iron through contact of the carbide of iron with the silica of the slag, in the blast furnace process, the relative surfaces of contact of these two constituents are as 1:1.26 approximately, whereas in the decomposition of Fe_2Si in the refining operation of puddling, the ratio of contact areas between Fe_2Si and the oxides $\text{FeO} \cdot \text{Fe}_2\text{O}_3$ is as 1:1. Hence it follows that more homogeneous interactions occur in the latter process. It is interesting to note that the

ratio: $\frac{\text{area of slag contact (sq. ft.)}}{\text{metal refined per hour (tons)}}$ is about 50, twice that of the open hearth steel process, the area of contact being sufficiently large to enable efficient washing and rabbling of the metal and slag to be carried out.

VII. *The liquid crystal phase.* Dr. Desch, in his recent invaluable contribution to the Institute of Metals, drew attention to the possible existence

of a liquid crystal phase at temperatures higher than the fusion point of metallic alloys. In the study of ferrous alloys the observed variations in the viscosity of hyper eutectic alloys when heated above their melting points, the decomposition of the carbide or carbides in carbon iron alloys as influenced by the presence of silicon, phosphorus, etc., resulting in a graphite-bearing viscous state, and the microscopic examination of such alloys when quenched from the superheated condition, all strengthen the view that above the liquidus curve of the phase diagram there may be

FIG. 5.

a liquid crystal phase. It is difficult to determine such a phase and its temperature limits, but there is much to suggest that liquid iron crystals more or less carbonised and siliconised in ordinary cast irons and steels do exist, and that their carbonisation and siliconisation are effected more rapidly as the temperatures approach the purely liquid phase.

Taking the fusion points of iron and iron carbide Fe_3C as 1500°C . and 1850°C . respectively, it might be found that a line drawn between the two (possibly not a straight line but a drooping curved one) would be the frontier line between the purely liquid and the liquid crystal phases.

In such a case the primary nuclei for crystal growth would occur within the liquid crystal phase and would not depend upon the freezing action in the now recognised solidus phase. Thus graphite may be precipitated in the liquid phase and act as the nucleus for the primary liquid crystals. Similarly silico-ferrite crystals may commence to form at the same or a higher temperature in the liquid phase and start a secondary ferrite liquid crystallisation.

It is in such considerations that the difference between crucible (a furnace with walls superheated above the temperature of the liquid crystal phase) melting and cold hearth melting appears. Just as the steam bubbles in a boiler rise most strongly from the zones next to the heating surfaces, so the occluded gases and convection currents within a molten metal in a crucible rise most powerfully from the zones next to the heated walls. These details may have much to do with the fineness of crystalline structure in the final cast metal and with the homogeneity or otherwise of such structure.

The fineness of such structure is related to the crystal boundary question and to the freedom from gaseous or refining oxide and slaggy inclusions within such boundaries.

VIII. It is instructive in this connection to trace the successive series of iron (liquid crystalline) deposition in the refining processes.

In Table 3 the possible order of iron crystalline deposition is shown in three well-known variations of the open hearth steel making processes.

The first stage of the operation in each case is that of melting the charge. In the liquid thus formed are the primary crystals (melted or as liquid crystals) originally present in the pig iron or steel scrap. The next iron addition to the bath is due to the decomposition of Fe_3Si , the Si entering the slag and liberating the iron of the silicide, coincidentally there being added to the liquid mass free iron reduced from the iron oxides of the slag. Manganese carbide is next attacked by the slag oxides and MnO enters the slag, being displaced by pure iron reduced from the iron oxides in the slag. After this comes the carbon elimination, the carbide Fe_3C on decomposition yielding its Fe to the bath and simultaneously adding pure iron reduced from the iron oxides in the slag. Finally when iron ore (Fe_2O_3) in excess of purely refining requirements is added to the slag, further iron is reduced and makes the final contribution to the mass of refined metal. The analyses and estimates given in the table are only approximate but are believed to offer a comparative view of the order of iron crystallisation during refining in the three types of steel making. Whether the iron increments are actually liquid crystals is as yet open to question.

IX. *Refined iron structures and superheating conditions.* In the U.S.A., J. E. Johnson, jun., the well-known blast furnace expert, has produced a cast iron which approximates in character to the finest charcoal cold blast iron such as is made in Sweden. By adding a cast iron which has been partly refined in a Bessemer converter to an ordinary foundry iron molten from the blast furnace the following actions occur.

The Bessemerised metal low in carbon content and containing considerable quantities of occluded gases and oxide particles is much higher in temperature than the blast furnace metal to which it is added. The superheating action on the latter

FIG. 6.

metal lays the unstable carbon and silicon as carbide and silicide of iron open to a secondary refining action. Some of the graphite is probably oxidised and iron oxide from the Bessemer metal becomes reduced within the mass. The result is a lower carbon iron with smaller nuclei of graphite than is found in hot blast pig irons. The relative action of slow and rapid refining is typified in the production of practically carbonless iron in the puddling and open-hearth furnaces well illustrated in the two photomicrographs, figs. 5 and 6 (100 diameters). Here the same raw materials were used in the open hearth and puddling operations, the resulting refined irons being of similar analysis. The two irons were similarly reheated, piled, and rolled. The difference in the size of the ferrite crystals is very pronounced, the puddled iron having much the coarser structure. The open-hearth iron, melted and refined under high superheat conditions, unassisted by artificial bubbling and agitation, has a finer crystallisation than the puddled iron, which is refined at lower temperatures. This latter action, carried out in a bath which is itself composed of active reducing oxides, must obviously tend to a coalescence and welding of adjacent iron grains or crystals which is impossible in a bath where the refining action proceeds by way of contact only with a superincumbent slag of low specific gravity and high viscosity. It goes without saying that the question of crystalline metallic structure is inseparably connected with the slag functions. Micrographic analysis cannot reveal the true character of the boundary films, the process of polishing the slag inclusions being altogether unsatisfactory when it is desired to reveal the characteristic structures at high powers of magnification. It would appear to be therefore of increasing importance to study the crystalline boundary problem in the light of the foregoing conclusions, bearing in mind the facts that the crystals or crystallites begin to grow in a liquid carrying oxides, slaggy, gaseous, or metallic.

These oxides, during their own decomposition, may form secondary crystals, or, in their passage to the slag covering, become entrapped as films within the contracting crystal boundaries.

Table 3.

Analyses of materials.	C.	Si.	Mn.	Fe.	Fe ₂ O ₃	SiO ₂	S & P.

THE ANALYSIS OF SOME ALUMINIUM ALLOYS.

BY J. H. STANSBIE, B.Sc.(LOND.), F.I.C.

The very rapid increase in the use of aluminium and its alloys for a variety of purposes has brought the metal into great prominence, and the analysis of the alloys for manufacturing needs has become of considerable importance. Much excellent and accurate work has been done in investigating methods of determining the impurities in the commercial metal and the constituents of its alloys. One of the latest contributions to the subject is by Mr. Withey of the National Physical Laboratory.

For works purposes, however, the methods of the investigator take up too much time, and shorter though less accurate ones must be used. But, considered from the practical point of view, this is not of importance, for as a rule an alloy is analysed because either it is found to be suitable for the work to which it is to be put, or it has failed to pass the usual tests, and the reason for its failure must be made clear. Now it may be contended that an analysis which gives the content of a constituent to within 0.1 per cent., or, in some cases, even more, is sufficiently accurate for the manufacturer, as he cannot hope to get within closer limits in making an alloy from a given formula.

A description of methods by which fairly rapid analyses of aluminium alloys may be made will, perhaps, be found useful, and may invite criticism as to their application. The writer claims nothing in the way of originality, but only the adaptation of known reactions to his needs; and will be pleased to know of any modifications which will either shorten the work or make it more accurate.

The alloys of aluminium which generally come under investigation contain one or more of the following metals:—zinc, copper, manganese, nickel, magnesium, tin, lead, and iron. The last two metals are commonly present as impurities introduced by the metals used in the production of the alloys. In some cases, however, the percentages of both lead and iron indicate that they have been purposely added. Silicon is always present as an impurity in the principal metal.

Preparation for analysis. If the alloy is supplied in bulk, sawings obtained by means of a moderately fine metal saw give good results. Turnings, drillings, or borings are not so convenient.

Silicon, copper, and manganese.

Treat 1 gram of the sawings with a mixture of 5 c.c. of nitric acid and 20 c.c. of dilute sulphuric acid (1 in 4). Digest on the hot plate till the metal is nearly all dissolved; add 1 or 2 c.c. of hydrochloric acid, and evaporate to fuming. A cover glass placed on the beaker should not condense any moisture. Treat with water and heat till all soluble matter is dissolved. Filter through an ashless filter into the beaker used for electrolysis.

Silicon. Ignite the filter paper in a weighed platinum crucible and weigh. Add 1 or 2 c.c. of hydrofluoric acid to the crucible and evaporate to dryness. Moisten the residue with water and add 2 or 3 drops of strong sulphuric acid from the end of a glass rod. Heat carefully and ignite at a red heat. Weigh. The loss in weight is taken as silica and is calculated to silicon.

As is well known, the residue may contain silicon as well as silica, but this may be neglected for present purposes. If the presence of lead is suspected the filter should be burnt in a porcelain crucible and transferred to the platinum one for evaporation. Any lead sulphate which passes through the filter will not interfere with the succeeding operations.

Copper. Add 2 c.c. of nitric acid to the solution in the beaker for electrolysis, and deposit the copper

on a clean platinum cathode. If a rotating cathode is used a current of 2 amperes at a pressure of 4 volts gives good results. The addition of nitric acid causes the copper deposit to be cleaner. The weight of the deposit gives the copper content.

Manganese. Transfer the solution from the electrolytic beaker to a conical flask. Add from 1 to 2 grms. of sodium bismuthate and shake well for 3 or 4 minutes. Set aside for a short time to settle, and then filter through an ignited asbestos filter, using a filter pump. Wash well with a 2% nitric acid solution. Add a measured volume of standard ferrous ammonium sulphate in excess. Titrate back with potassium permanganate solution. The percentage of manganese is calculated from the volume of the iron solution required to decolorise the solution containing the manganese as permanganate.

A solution of ferrous ammonium sulphate containing 10 grms. of the salt and 10 c.c. of strong sulphuric acid in 500 c.c. is of convenient strength and 1 c.c. = 0.000562 grm. of manganese. This solution undergoes very little change on standing.

The permanganate solution should be of approximately the same strength, and the simple plan is to run in another 5 c.c. of the ferrous solution to the original solution, titrating back as before. In this way the value of 5 c.c. of the solution (ferrous) in terms of the permanganate is known, and a simple multiplier found for determining the excess of the ferrous salt added in the first instance. Then vol. of ferrous solution oxidised $\times 0.000562$ = weight of manganese in 1 gram of the alloy.

Copper, iron, lead, zinc, nickel, manganese, magnesium.

Add 60 c.c. of 10% sodium hydroxide solution to 2 grams of the sawings and digest on the hot plate till all action ceases. Allow to cool, add a little water, but keep the bulk of solution small. Filter through a pulp filter, collecting the filtrate in an electrolytic beaker. Wash the residue with small quantities of hot water. The beaker containing the filtrate and washings should not be more than two-thirds full.

The solution contains aluminium and zinc, and is subjected to electrolysis. The zinc is deposited on a copper-coated cathode by a current of 0.6 to 0.8 ampere passed for about 45 minutes, using a rotating cathode. The deposit should be well washed with cold water from a wash bottle while over the electrolytic beaker, and then vigorously moved round in a beaker containing distilled water to remove the last traces of the soda solution. It is then ready to be dipped into alcohol, dried, and weighed. The weight of zinc in 2 grams of the alloy is thus obtained.

Messrs. Ibbotson and Aitchison state that the zinc deposit is free from aluminium and this is also the writer's experience. The deposits of copper and zinc may be dissolved from the cathode, and redeposited without loss of weight.

The solution may be used if required for the determination of the aluminium, but in that case it should be diluted to 500 c.c. and 50 c.c. taken. It is sufficient, however, to take the aluminium by difference, when the other constituents have been determined.

The black residue on the pulp may contain copper, iron, lead, nickel, manganese, and magnesium, and is treated with nitric acid (5 c.c. of strong acid and 7 c.c. of water) in small quantities at a time, washing with hot water after each addition. The solution is collected in an electrolytic beaker, 3 c.c. of sulphuric acid added, and the copper deposited on the cathode. A check on the metal is thus obtained. If lead is present it will show on the anode. In that case the peroxide is allowed to dissolve off the anode and the solution evapor-

ated to fuming. A little water is added, and the beaker allowed to stand for the lead sulphate to settle. The lead is determined in the usual way. If more than 1% of iron is present, the pulp will be dark coloured, and should be treated with hydrochloric acid and washed. The washings are added to the filtrate containing the bulk of the iron. If manganese is present it is already known from the preceding operations.

A few c.c. of hydrochloric acid to form ammonium chloride is added to the filtrate, or to the solution if lead is absent, and then ammonia in slight excess, together with 10 c.c. of ammonium acetate if manganese is present. It is then boiled for two minutes, and the precipitate containing iron and aluminium filtered off. (Traces of aluminium are always retained on the pulp, and pass through with the other metals when the residue is dissolved.)

The filtrate may contain manganese and magnesium. The former is removed by hydrogen sulphide, and the filtrate from the sulphide boiled to expel excess of gas, or the manganese may be separated by bromine and ammonia in the usual way. The magnesium is precipitated as phosphate. This method is recommended by Mr. W. Gemmell.

The precipitate containing the iron and aluminium is dissolved in hydrochloric acid, the solution neutralised with sodium carbonate, and one or two drops of the acid added to clear. The solution is then raised to boiling, and poured slowly into a boiling solution of sodium hydroxide containing about 5 grams of the alkali. The iron is thus precipitated free from alumina, and is filtered off. The precipitate after well washing is dissolved in hydrochloric acid, reprecipitated by ammonia, and the iron determined.

An alloy containing tin can be treated directly in the usual way with nitric acid, and the tin separated as oxide.

The analysis of the alloy given below was carried through on the lines indicated above :

Aluminium	= 83.16 (by difference)
Zinc	= 11.54
Copper	= 3.30
Iron	= 0.62
Manganese	= 0.49

	100.00%

The Rev. F. G. Belton has furnished me with the following description of a process for the determination of nickel in aluminium alloys which he is investigating with, up to the present, very fair results.

1 gram of the alloy is dissolved in 25 c.c. of caustic soda solution (100 grams in 500 c.c.) and allowed to digest for about two hours. The solution is diluted somewhat with water and filtered through a pulp filter, the residue is washed with hot water, and dissolved in 5 c.c. of concentrated nitric acid to which has been added 7 c.c. of water. To the solution thus obtained is added 3 c.c. of concentrated sulphuric acid and the copper is estimated electrolytically. The solution is now made up to about 150 c.c. and 10 grams of tartaric acid together with 3 grams of ammonium chloride are added to keep in solution any aluminium that may be present. Ammonia is added to the solution in slight excess; too great excess is to be avoided as it retards the precipitation of the nickel. The distinctly alkaline solution is now heated to about 50° C.; a higher temperature is to be avoided. A sufficient quantity of dimethylglyoxime (prepared as a 1 per cent. solution in absolute alcohol) is added to precipitate the nickel as dimethyl nickel glyoxime. The precipitate is flocculent and bright red in colour, and does not settle easily. It is allowed to stand for about 15 minutes at 50° C. and then filtered either on pulp or ordinary filter

paper, the latter seems preferable when the nickel is present in fairly small quantities. The dimethyl nickel glyoxime is slightly soluble in water, and the precipitate should be washed with a dilute solution of ammonium nitrate. As the nickel compound is volatile it should be dried as follows :—The wet filter paper containing the nickel is wrapped up in a second wet filter paper and placed in a porcelain crucible (when a pulp filter is used it is best to wrap up in two wet filters); this is introduced at once into the front of the muffle so that it may char quickly; when the charring is complete the crucible is placed in the hottest part of the muffle, and the precipitate is ignited to green nickel oxide.

DISCUSSION.

Mr. JOHNSON said he could testify to the care and interest with which Mr. Stansbie had got together the details of his paper. They had dealt at the local laboratories with many of the alloys.

Mr. HEATHCOTE said that sometimes iron was found to be present in aluminium castings, but where it came from he could not say.

Mr. LANTSBERRY stated that when 25 alloys had to be examined in a day, and it was found that some methods necessitated the use of expensive apparatus, one had carefully to consider which method should be used. Nickel was sometimes contaminated with iron. That was due to the fact that insufficient tartaric acid had been used.

Mr. STANSBIE, in replying, said that by the use of sodium sulphide all zinc could be precipitated.

ELECTROLYTIC COPPER.

BY F. JOHNSON.

The commercial electrolytic refining of copper commenced in the year 1860 by Elkington at Pembrey, S. Wales, batteries being used as a source of current. A very high-grade commercial copper (best select) had been produced by the Welsh process, but its purity was variable and its electrical conductivity neither sufficiently high nor regular; the process moreover failed to recover the precious metals.

In the "eighties," however, electrolytic copper refining was established, on a satisfactory footing and has since then grown and developed with remarkable rapidity and technical success.

The series and multiple systems are both in vogue, the former having been restricted in its use owing to the employment of a suitable generator for the multiple system.

In a paper read at the International Engineering Congress at San Francisco, Sept. 20—25, 1915, A. C. Clark stated that the quality of electrolytic copper had greatly improved. Early production was irregular in quality, owing to the presence of impurities, and sold at a discount from the price of Lake copper. At the present day the disparity in price still exists, although electrolytic copper is now uniform in quality and purer than Lake copper. The early irregularities in quality were due to engine or generator troubles, insufficient circulation of electrolyte, undue variation in temperature, irregular chemical composition of solution, etc. The present-day cathodes of electrolytic copper are usually tough and smooth and assay 99.96% copper, the conductivity being frequently 102% of that of Matthiessen's standard (the best then supposedly obtainable) in 1865.

Cathodes are now melted in furnaces having a capacity of over 200 tons. Silica brick has now been replaced by magnesite or chrome brick, and a considerable saving in slag production and cost of repairs has thus been effected.

The author has many times given attention to

the substitution of a neutral or basic material such as chrome or magnesite brick for silica brick in copper refining furnaces, but has invariably had to reject the idea on the grounds of expense. It is a significant fact that in the large refineries of the United States, according to the direct testimony of a practical American metallurgist, the introduction of these bricks has actually resulted in economies in slag production and repairs. Such economies would be inevitable, but whether they are so great as to more than outweigh the increased initial cost is not stated.

It would appear as though a trial on a manufacturing scale in this country would not be without justification.

The cathodes are introduced into the furnace by charging machines and metal is tapped from the furnace and run into ingots or wirebars by the aid of some form of casting machine. In the Clark and Clark casting wheel used at the Raritan works, the copper is tapped from the furnace into a ladle, six bars being poured simultaneously into moulds set radially on the casting wheel.

Addicks, in a paper read at the same Congress, claims that the cost of refining on these lines is less than half that of refining in the best of the old hand-ladled furnaces.

Furnaces are charged at the rate of 140 tons per hour. Melting is accelerated by forced and induced draught and boilers are fired by the waste furnace-gases. With increase of size of furnace, coal consumption has decreased from 20% with an 18-ton charge to 10% with a 270-ton charge. Silica is not allowed to come in contact with the bath of metal, thus resulting in a reduction in slag production from 4 to 1%. Crushed coke of low sulphur content is used instead of charcoal to cover the charge, poling being carried out exactly as in the older process. Fettling is practically unnecessary in the basic lined furnace. The metal is ladled out at the rate of 40 tons per hour.

The figures quoted appear almost grotesque in their magnitude when compared with those of English practice, and it is extremely doubtful whether the latter will ever conform to the high efficiency of copper metallurgical practice in the United States, owing to the fortunate position which that country enjoys in her possession of such vast mineral resources. There are, moreover, other very striking points of difference between English and American practice. Most English refineries are worked in conjunction with rolling mills and in many instances firms have to manufacture an extraordinary variety of materials.

It is no uncommon thing in an English refinery to produce in a single week arsenical billets and cakes, B.S. ingots, and high conductivity wirebars from the same furnace.

It is generally arranged for a charge or so of ingot copper to succeed an arsenical charge prior to melting a charge of electrolytic copper, the ingot charge serving to wash the furnace and being less susceptible to the contamination of any residual arsenical copper from the preceding charge. Owing, therefore, to the fluctuating character of the trade and the multifarious requirements of customers in a country where hitherto the volume of trade has never been sufficiently large to justify the enormous initial expenditure involved in the American system of specialisation, furnace refining plants remain small and electrolytic refining is left almost entirely to the United States, a relatively small amount being also done in Australia and Japan. Nevertheless, high conductivity copper wire, sheet, etc., of first class quality is produced in this country and great credit is due to English refiners for being able to maintain such a high standard of quality in spite of their severe handicap.

There is something to be said in favour of the old system of hand-ladling as regards the physical condition of wirebars and cakes. As the author

has pointed out, the level "set" of wirebars, etc., is entirely the result of a compromise between occluded gas and cuprous oxide. With excess of the former the metal would be "overpitch" and spongy, whilst an excess of the latter would result in the metal being "underpitch" and brittle.

With hand-ladling, solidification proceeds as the mould fills and little time elapses from the moment the last ladleful is in the mould until the moment of complete solidification; hence the opportunity afforded for the escape of occluded gas is small and the "set" will be normal.

With machine ladling, unless the rate of pouring be retarded, the mould will fill very rapidly, there will be a greater lapse of time before filling of mould and solidification, and therefore greater opportunity for the release of occluded gas. With less gas in the metal, shrinkage will have less opposition and will occur at local points, forming minute "pipes" or shrinkage-cavities which have communication with the outside air and therefore become oxidised. Their formation is also encouraged by the rapidity with which the mould is filled.

The occurrence of these may be detected by the appearance of black specks on the surface of a solidifying ingot or wirebar. Their presence is obviously inimical to the production of perfect homogeneity of structure and would adversely affect the physical properties of wire, sheet, or rod, to say nothing of their responsibility, in part, for troubles in the mill.

* In the United States, furnaces are classified into anode and cathode furnaces. In the former the charge consists of rough Bessemerized pigs which undergo a refining in part and are cast into slabs of special size and shape which serve as anodes in the electrolysing vats.

The electric current passing from these anodes through a strongly acid bath of copper sulphate deposits copper on specially prepared cathode starting sheets, which, when coated to a sufficient thickness, become the cathodes of commerce, and are transferred to a cathode furnace, in which they are melted, brought to correct "pitch," and ladled out into ingot, cake, or wirebar.

The recovery of precious metals from the electrolysing vats, in the form of insoluble slimes, plays a big share in the commercial success of the process.

Addicks, in a paper to the American Inst. of Metals, vol. VIII., 1914, p. 165, makes the following remarks:—"It is quite evident that copper entering an electrolytic refinery must entirely lose its identity and that the purity of the resulting cathode copper will depend upon the conditions under which electrolysis is carried out rather than upon the momentary quality of the day's anodes. Therefore it is not necessary to consider whether the input be converter bar, black copper or Lake mineral when buying electrolytic, but simply whether the product meets the accepted standards of quality of electrolytic copper."

"Electrolytic cathodes should be very pure. They generally run about 99.95% copper, much of the remaining 0.05% probably being hydrogen.* The metallic impurities generally total about 0.02%. Except for the fact that individual cathodes may vary more or less in impurity content, they are ideal material for brass making. Copper producers, however, have never encouraged the sale of cathodes as there is apt to be some shrinkage in weight during shipment owing to the comparative ease with which nodules or small pieces can be detached either accidentally or intentionally. Also cathode shipments unbalance the work in a refinery in proportion to their magnitude, as melting cathodes into market shapes is a distinct part of the process."

* See note on hydrogen later.

" This melting is done in a reverberatory furnace and originally was an exact duplication of the fire-refining already described.

" As the cathode copper is already pure, a simple melting is all that should be required, but molten copper is so susceptible to contamination that until recently the gases from combustion, iron in the rables, etc., were absorbed to a sufficient extent to require actual refining. At the present time large quantities of cathodes are being added to the molten charge during ladling and earlier, basic furnaces being substituted for acid ones—thereby suppressing slag formation—and attention is being paid to keeping coal ashes from blowing over from the firebox so that a true melting without refining is being approached. It is well known that cathode copper when drawn into wire will show an electrical conductivity some 2% higher than the same copper after a subsequent fire refining. This is probably due partly to the fact that chemical impurities in the cathode are chiefly present as a mechanical mixture due to adherence of anode slimes which are dissolved in the copper when melted, making a high resistance matrix around the copper crystals when the metal is cast and cooled; and partly to contamination during melting.

" It seems probable that the conductivity of perfectly pure soft copper is in the neighbourhood of 103% of the Matthiessen's standard in common use."

The author is not in agreement with Addicks regarding the explanation offered of the increase in resistance by the formation of an intercrystalline matrix. As will be shown later, it is the impurities which enter into solid solution which have the most serious influence on electrical conductivity and that influence persists even after the elimination by annealing of any concentration of impurity at the crystal boundaries, such as may result from "coring" or micro-chemical heterogeneity. Arsenic, for instance, is discernible under the microscope in cast specimens by the existence of arsenic-rich fringes surrounding "cores" richer in copper.

FIG. 1.

Copper containing 0.26% oxygen as cast. Magn. 200 dia

When such copper is drawn into wire (and this process requires many annealing operations) the "cored" appearance will have completely disappeared and the structure will not be distinguishable from that of pure copper, but the resistance

will nevertheless be not appreciably less than that of the cast specimen.

Whilst dealing with the question of intercrystalline matrices it is a matter of interest to point out that in commercial copper no substance forms so definite and unmistakable a matrix as cuprous oxide (in the form of copper-cuprous oxide eutectic); and yet no substance has, in equal proportions, so harmless an influence upon conductivity.

FIG. 2.

Copper containing 0.20% oxygen. Magn. 200 dia.
Annealed 5 hours at 900° C.

From the accompanying photomicrographs, prepared by the author, it will be seen how annealing causes coalescence of the cuprous oxide globules in the eutectic and eventually would destroy the intercrystalline continuity of the latter. What effect, if any, this coalescence has upon conductivity the author has not yet determined.

Refining of anode slimes.

The old fire-refining processes are still in vogue but are looked on with some disfavour owing to the high metal losses.

By simply fusing the slimes three products are obtained, viz. :—

Bullion, containing lead, copper, and the precious metals.

Matte, containing copper, silver, selenium, and tellurium.

Slag, containing arsenic, antimony, and similar readily oxidised metals.

The formation of matte may be largely reduced by roasting the dried slimes before melting and dissolving out the oxides of copper as sulphate. The base bullion is refined in a small reverberatory furnace with basic hearth by the use of air under pressure, and nitre. Part of the slag is returned to the anode furnaces, part remelted to cause a separation of entangled prills of metal, and the remainder recharged into the refining furnace.

Silver is parted from gold usually by an electrolytic process, the gold slimes being treated for the recovery of platinum and palladium. The flue dust from the silver refinery is leached and the selenium recovered by reduction with sulphur dioxide.

When the anodes assay 99%, and over, the remainder may contain any proportion of arsenic, nickel, etc., if the electrolyte contains from 2.5 to 3% copper and 12% free sulphuric acid. Purification of the electrolyte may be effected by diverting a proportion every day into separate tanks

containing insoluble anodes. Copper and arsenic, etc., are deposited under special conditions at the cathode in a loose condition.

During the process of electrolysis, the solution, if stationary, will, owing to the differential rates at which the anode passes into solution and the copper deposits on the cathode, become heterogeneous in composition. There is a tendency to stratify or form layers of various compositions. In order to avoid this stratification, with its attendant troubles of short circuiting, disintegration of anodes, irregularly shaped cathodes, etc., the electrolyte is usually circulated. The rate of circulation is important, as if too slow, the stratification is not obviated and if too rapid the cathodes are contaminated by the suspended slimes, thus lowering their purity and resulting in losses of the precious metals.

Pyne ("Solution stratification as an aid in the purification of electrolytes," Amer. Electro-Chemical Society, 1915) proposes to take advantage of this stratifying tendency in order to secure a low copper content in the daily portion withdrawn for purification, and thus dispense with the operation of one of the two sets of insoluble anode tanks. This is effected by having two outlets, one at the bottom and one at the top, and so regulating the inlet flow that a weak solution withdrawn from the upper outlet is delivered to the insoluble anode tanks, while the strong solution withdrawn from the lower outlet is returned to the circuit.

Schröder (Australian Mining Standard, 1910, 44, pp. 659 to 660, and 1911, 45, pp. 7 to 8) found that the loose cathode deposit in the second set of insoluble anode tanks contained Cu 71%, As 3.5%, Bi 1.6%. The firm cathodes were not so impure, containing Cu 98.2%, As 0.18%, Bi 0.25%.

Influence of impurities on conductivity.

The table below gives analyses and physical properties of some well-known brands of commercial copper. An examination of the figures given will reveal the variety of the impurities and the minuteness of the proportion in which these impurities exist. Thus it is necessary that the chemist whose

a study of the figures, it is hardly possible that the oxygen content could be so low in wirebar-copper as is shown in two cases quoted by Guillet. It is notorious that the extremely pure electrolytic copper produced in the United States requires less oxygen than the less pure European brands, but the author has never found by direct determination proportions of oxygen so low as 0.0191 and 0.0063% in commercial copper.

The conductivity of two samples of Lake copper is given as over 101%, in spite of the presence of 0.07% of silver, which, according to Addicks, would, *per se*, lower the conductivity to practically 100%. Arsenic, iron, nickel, and sulphur are also present, and considerably more oxygen than in the samples quoted by Guillet, yet the conductivity is superior to that of Guillet's purer samples.

Hofman states that the conductivity of cast copper is about 3.5% lower than that of annealed wire. The author is not prepared to accept this figure, but judging by the results of his annealing experiments, showing the breaking up of continuity of the eutectic and causing coalescence of the cuprous oxide globules, as already described, it would appear that some improvement in conductivity might be expected to accompany such structural change. The increase in density as a result of the closing up of pores by rolling and drawing would also contribute towards increase of conductivity.

The influence of oxygen both throughout the refining process and as a permanent constituent of the finished metal is of profound importance.

It may be accepted as an indisputable fact that there is at present no known method of producing commercial ingots, wirebars, etc., of copper, having a level surface other than by the process of "poling." This process, as the author has already indicated, introduces gases into the copper which oppose the natural shrinkage of the metal and in the proportion necessary for the production of "tough-pitch" copper do not have an appreciably harmful influence. Any such influence is either mitigated by the subsequent mechanical treatment of the metal or, if the copper is destined to be used for making alloys, eradicated by

Chemical analyses of refined copper.

duty it is to make analyses of modern brands of copper must be a man of first-class training and considerable experience.

There is one feature of the analyses that calls for criticism and that is the reporting of the oxygen content by difference. As may be gathered from

remelting. It has been shown that "poling" removes the excess of oxygen in a furnace charge, and it is now necessary to explain that if the process were continued until the last traces of oxygen were removed, the resulting metal would be "overpoled" and unfit for use for two reasons:—

(1) The copper here would contain too much dissolved arsenic, and all ingots or castings would be spongy owing to the release of such gas during solidification.

(2) The protective influence of the oxygen which is of necessity retained in the "tough-pitch" copper extends beyond the checking of gases from dissolving in excess to the neutralising of the harmful effects of certain impurities.

Thus all furnace-refined copper will contain some oxygen in the form of cuprous oxide, and the author is convinced that the lower the oxygen content can be kept, with safety, the better, since with the useful functions already mentioned the technical advantages of oxygen cease.

The influence of oxygen on the conductivity of copper for electrical purposes has been dealt with by Addicks (Trans. Amer. Inst. Min. Eng., 1906, p. 18), T. Johnson (Proc. Birmingham Metall. Soc., 1906), and Hoffman, Hayden, and Hallowell (Trans. Amer. Inst. Min. Eng., 1907, 38, 147). Addicks and the last-mentioned investigators prove that the electrical conductivity of electrolytic copper is improved by the presence of a certain small quantity of oxygen. Addicks, indeed, after investigating the influence of a large number of impurities, found that oxygen alone has a beneficial influence, but beyond that proportion which is usually found in "tough-pitch" copper, the conductivity again commences to fall. The author (J. Inst. Metals, No. 1, 1912, pp. 242-243) has suggested that this influence of oxygen is not a direct but an indirect one, the oxygen having the ability to change the condition in which certain impurities in minute traces exist in copper. If, for instance, a trace of antimony (of the order of 0.002%) is retained in electrolytically-deposited copper, the antimony will be retained in solid solution in the copper if melted down free from access of oxygen, and the copper in consequence will not possess its highest possible conductivity.

The admission of a small percentage of oxygen, however, affects the condition in which antimony can exist in copper as shown by the author (J. Inst. Metals, No. 2, 1912). Greaves (J. Inst. Metals, No. 1, 1912) has also shown that the electrical conductivity of antimonial copper is slightly raised by the addition of oxygen.

Therefore, it is not surprising that, by preventing some of the antimony from entering into solid solution as dissolved Cu_3Sb —in which condition it doubtless exerts its maximum deleterious effect—the oxygen indirectly improves the electrical conductivity.

Naturally, that antimony which was prevented from entering into solid solution was combined with oxygen in certain proportions, forming "oxides" or isolated particles which would not offer the same resistance to the passage of an electrical current as the antimony would do when retained in solid solution.

The figures of Addicks are interesting and are given below.

Oxygen.	Elec. conductivity.
%	%
0.020	100.7
0.050	101.4
0.100	100.5

Influence of arsenic upon electrical conductivity.

Addicks, T. Johnson, and Hiorns and Lamb have given some attention to this subject and although there is some disparity between their results, they all agree that small quantities of arsenic are absolutely fatal in copper required for electrical purposes. A selection of results is given here-
with:—

Percentage of arsenic.	Investigator.	Electrical conductivity.
0.004	Addicks.	% 99.6
0.007	Addicks.	96.8
0.013	Addicks.	93.2
0.04	T. Johnson.	92.4
0.05	Hiorns and Lamb.	79.4
0.06	T. Johnson.	82.0
0.098	Hiorns and Lamb.	69.5
0.14	Addicks.	62.4
0.182	Hiorns and Lamb.	61.1

It will be noticed that the last result of Hiorns and Lamb disturbs the comparatively satisfactory agreement between the previous results. Such discrepancies as exist are probably explainable by the fact that none of the investigators attempted to determine the amount of oxygen (if any) in their alloys. That this element can affect the influence of arsenic on the conductivity of copper has been shown by Greaves (J. Inst. Metals, No. 1, 1912).

The following is an example from Greaves' paper:—

Composition.		Relative conductivity. (Copper = 100).	Relative conductivity. Copper-arsenic without oxygen.
Oxygen.	Arsenic.		
% 0.10	% 0.49	% 35.2	% 42.4

The most systematic study of the influence of impurities on conductivity has been made by Addicks and a review of his results establishes some important points in connection with the relations between influence on conductivity and structural condition.

A large number of the elements have a comparatively slight effect, whilst some have an effect which seems out of all proportion to the minute quantities involved.

If these elements are classified according to their physico-chemical behaviour, when alloyed with copper, some clue will be afforded as to the reasons for their differing influences on conductivity.

Group 1. Elements which exist as insoluble constituents, either pure metal or compound, viz.:—Lead, bismuth (as pure metals), oxygen, sulphur, tellurium (as compounds).

Group 2. Those which enter into solid solution but not as intermetallic compounds, viz.:—Silver, gold, zinc, iron, tin, (cadmium?).

Group 3. Those elements which enter into solid solution as compounds, viz.:—Antimony, silicon, phosphorus, arsenic, aluminium.

It will be seen that, roughly, this grouping of the elements has a connection with influence on conductivity.

The specific resistance of the individual element is not an index as to its influence on conductivity (cf. figures for silver and lead), nor is its place in the Periodic Table of Mendeléeff, nor its atomic volume.

The author does not put forward his grouping as a complete solution of the problem, but it appears to be a step towards establishing a solution. Other factors which probably enter into the question are the specific resistance of the elements, and of the compounds which are held in solid solution. For instance the intensity of the effect produced by silver, gold, zinc, and iron increases in the order of these metals in the table of conductivities. Tin appears to act in an exceptional way.

The most striking fact, however, is the profound depression of conductivity produced by an impurity which enters into solid solution as a compound, e.g.

phosphorus as Cu_3P , arsenic as Cu_3As , aluminium as Cu_3Al , and antimony as Cu_3Sb .

In this category silicon acts in an exceptional manner as, according to Vigoureux and Lebeau (*Comptes Rendus*, 1906, 142, 87 and 151) it forms the compound Cu_3Si , which enters into solid solution.

The impurities given in Group I, which exist as insoluble constituents, have an influence on conductivity roughly proportional to the quantity present, which is, in commercial electrolytic copper, practically negligible.

Influence of annealing upon cold-rolled copper.

In a most interesting paper by Bardwell (*Bull. Amer. Inst. Min. Eng.*, 1914, 2075) the effect of annealing temperatures on electrical conductivity and the mechanical properties is described.

Six cold-rolled rods of copper, the oxygen content of which varied between 0.036 and 0.070%, were annealed in an electrically heated muffle. There was a great similarity in the behaviour of all six specimens. A very small increase in electrical conductivity is produced until a temperature of 300°C . is reached, at which temperature the increase is extremely rapid, reaching a maximum at 430°C . Above 650°C . there is a marked falling-off in conductivity.

This falling-off in conductivity as a result of annealing at too high a temperature is a result which one would scarcely have been led to expect from a knowledge of works practice. There is no indication given that the electrical conductivity would be recovered by subjecting the over-annealed samples to further cold-drawing and annealing at a safe temperature. The increase in conductivity at 300°C . occurs conjointly with a rapid fall in tensile strength and increase in elongation. These points are well brought out in the curves in Fig. 3.

FIG. 3.—Variation of Physical Properties of Copper Wire with Variations in Annealing Temperature.

The falling off in conductivity at high annealing temperature is so serious as to call for further investigation and confirmation.

Credner (*Z. physik. Chem.*, 1913, 82, 457) attributes the increased resistance of a stretched wire to the orientation of the lamellae. He claims that there is no evidence of the formation of an amorphous phase. Torsion or bending is said to produce cavities with accompanying increase of resistance which is not removed by annealing. Bardwell points out that twinning is conspicuous in the crystals of annealed copper, the appearance of "polysynthetic" twin crystals coinciding with decrease in conductivity and elongation.

The author is of the opinion that until a rational and generally accepted explanation of the

hardening of metals by cold work is established, the increase in electrical resistance accompanying that phenomenon cannot be satisfactorily explained.

In conclusion, it may safely be said that there appears to be no prospect of any marked improvement in the purity, quality, and conductivity of electrolytic copper if produced under the best modern conditions.

Conductivity is affected adversely by heat, by impurities, and by hard drawing. Of no single element can it be said that its introduction to copper has any other effect than a lowering of electrical conductivity. In the case of oxygen, its power of altering the chemical condition in which other impurities exist and thus lowering their power of resistance may bring about a corresponding gain in conductivity, which may more than offset the loss of conductivity caused by the oxygen *qua* cuprous oxide. Those impurities which are most detrimental to the working properties of copper have least effect upon electrical conductivity. There is (according to Bardwell) a critical annealing temperature range beyond which a falling-off of conductivity may be expected.

The papers by Dr. Lantsberry and Mr. Kent Smith will be published later.

DISCUSSION ON PATENT LAW REFORM.

Dr. A. RÉE, in opening the discussion, said:—A good many people are taking an interest in Patent Law reform now, who gave no attention to this rather dry and uninteresting subject a few years ago. The fact is, they are at last realising that much that is not quite satisfactory in our industrial position may perhaps be due to our Patent Laws, which work in some respects against rather than in favour of this country as a whole. Gradually a system has arisen which has tended more and more to obscure the original and most important object of a Patent Law, the furthering of new industries in the country granting this greatest of monopolies. And when you come to think of it, it is not so very surprising that this should have happened. The formulating of the laws, their interpretation and administration, are almost necessarily left to what may be broadly described as certain professional elements, particularly to lawyers and patent agents, many of whom naturally look upon these questions from an entirely different point of view to that of the business man and manufacturer. For the former is primarily concerned in looking after the interests of his clients and incidentally his own, for which no one can legitimately blame him. And yet this is no doubt partly responsible for a good deal that is unsatisfactory. In the formulating of new measures and recommendations, manufacturers and business men have rarely been consulted, and if they have, their views have generally been subordinated to those of the professional element. And who has guarded the interests of the State? Practically no one. Hence have arisen some of the worst abuses.

In no department has this been more apparent than in the much-discussed question of compulsory working and licences. About 30 years ago these subjects became what I believe Americans would call live ones in the Manchester Chamber of Commerce, and they have continued to occupy the attention of its Engineering, and especially its Chemical, Section, almost ever since. We worked for years and years, trying to get the Board of Trade to realise the need for the reforms we advocated, particularly in respect to compulsory working. Finally, we came within measurable distance of success. It was when our present Prime Minister was President of the Board of Trade. With that extraordinarily quick per-

ception that is his, he saw at once the great possibilities of benefit to this country if the measures for which we stood were adopted. The 1907 Act embodied these measures, and had Mr. Lloyd George remained a little longer at the Board of Trade, we should not to-day have to ask for a reversion to the condition of things in respect of the compulsory working clauses which obtained and were incorporated in that 1907 Act, but which were rendered so largely nugatory by a judgment of Lord Parker shortly after that Act was passed.

Well, now, since the war the eyes of a great number of people have been opened to the mistake of granting foreign owners of British patents all those great and far-reaching privileges that a patent monopoly confers without exacting from them any sort of countervailing advantage to this country. We were really working under the most quixotic form of protection imaginable, viz., the protection of the foreign holder of British patents to the detriment of the home manufacturer. The former secured his patent in order to prevent manufacture here, not in order to establish a new industry, far and away the most important reason for the granting of a patent monopoly. The German owners of British patents were, needless to say, fully aware of those benefits to themselves. It is not, therefore, surprising to find that they were the most embittered opponents of any measures destined to alter the laws in the direction desired by the Manchester, as well as by the Associated Chambers of Commerce. For years and years every device was used to prevent the attainment of the objects the latter had in view. This went so far that I understand representations were made that if we changed our laws in the direction of enforcing compulsory working this would inevitably lead to retaliation. It is amusing that this threat was used by the representatives of those German concerns who themselves had at the time clauses in their Patent Act far more stringent than ours.

The question is frequently asked why will not compulsory licences do instead of compulsory working? The former were tried here for a great many years and were a complete failure, i.e., practically no licences were applied for over a period of at least 20 years. The principal reason was that most chemical patents require years of experience in working before they become a commercial success. Suppose indeed after a long period one were to obtain a licence for, say, a complicated chemical process, all one would get would be almost useless. To have an industrial success, the licensee would have to devise special plant and all kinds of ingenious contrivances, which count for so much in the successful carrying out of an invention. These the foreign patentee would know but there would be nothing to compel him to divulge them to the licensee. The patentee would be years ahead in any case and would consider it quite natural to hamper and delay the licensee in every conceivable way. Unless indeed the latter had the goodwill of the patentee, which was rather unlikely after a big fight in the Law Courts involving great expense in time and money, all the licensee would finally get would not be worth having. How many chemical patents are there that are worked strictly in accordance with the final specification? Hardly any, those who have most experience will, I feel sure, admit. This is an explanation why so much of the legislation of the past decades in this respect has been a failure and why, in fact, compulsory licences were not sought. (To prevent and forestall criticism may I, however, make the reservation that what I have just stated does not apply to war time, when of course a totally different condition of things obtains.)

The question is sometimes put, What beneficial results can you point to as the result of the intro-

duction of compulsory working? Well I can cite many instances of industries that have been started in this country as a result of the 1907 Act or in anticipation that compulsory working would be introduced and effectively carried out. I will only mention the following: Linotype machinery, the British Westinghouse Co., the British Shoe Machinery Co., the Diesel engine manufacture, artificial silk, artificial stone and tiles (Hatschek patents), safety razors, metallic filament lamps, cinematograph films, gramophones, cash registers, artificial indigo, and a few pharmaceutical and artificial food products. However if there were only the well-known case of artificial indigo, I think that would in itself show how beneficial and in fact essential it is that there should be compulsory working. I have gone into this case so fully elsewhere that I feel it is unnecessary to recapitulate the details here.

It should always be borne in mind, that the compulsory working clauses in the 1907 Act were only effectively in force for about 15 months, i.e. until Lord Parker's judgment. Further there is this most important consideration, emphasised by the Comptroller-General in 1914, viz.—that he had good reason for believing that the fear of revocation of foreign-owned British patents worked abroad and not here had resulted in a good many foreign patentees granting licences on reasonable terms to British manufacturers to work their patents here. I am afraid, however, that this applies chiefly to mechanical patents and not to chemical ones. The latter are now a days often exceedingly complicated and to make them an industrial success needs years of intricate study and the devising of complicated machinery and the discovery of ways and means of carrying on all kinds of operations, which the patentee knows but does not communicate to the licensee. If the patentee had to work here himself he would take care to work under the most approved conditions known to him, and then on the expiry of the patent the manufacture would be established here on sound and competitive lines, instead of becoming a permanent monopoly abroad.

A very important point is also that compulsory working is more essential for us in this country than anywhere else. For where you have protective duties and industrial conditions are also otherwise favourable, it is manifestly to the patentee's interest to work his patent in that country himself or grant licences to existing manufacturers, giving the latter all the benefit of his acquired knowledge beyond what is contained in the patent specification. But under our system of fiscal policy a foreign patentee had not that inducement to manufacture here. So we needed the spur of compulsory working to induce him to do so on the penalty of losing his patent if he failed to comply. Only thus was it possible to counteract the positive evil that had grown up, whereby the granting of a patent to a foreigner who worked it in his own country but not here, resulted in the worst form of protection imaginable—a protection and a monopoly in favour of the foreigner, generally a German, to the detriment of the British manufacturer and to the serious loss and inconvenience of this country generally.

Now to make the compulsory clauses really effective we must revert to an interpretation of them, that existed prior to Lord Parker's judgment in the Hatschek case. The onus of proving non-working or inadequate working here of British patents worked abroad rested until then on the patentee. The need for this was already clearly stated by Mr. Lloyd George. Then came this unfortunate judgment of Lord Parker. The arguments used for putting the onus of proving inadequate working on the applicant for revocation were mainly on the grounds that it is unreasonable to call upon a defendant (the patentee) to

prove or disprove plaintiff's case. This really reduces the clause to an absurdity. For it is obvious that all the patentee has to do is to refuse any information as to adequate manufacture here, and how then is applicant to proceed to discover the facts? He may produce one witness after another to say that he is unaware of any manufacture in this country, but that is no proof of non-working. As the patentee escapes revocation of his patent if he works it here on an adequate scale, he should be prepared to justify his plea and prove that he manufactures here or that there is a good cause why he does not manufacture here. Then as to the contention that it would be contrary to the first principles of English law that defendant should be called upon to prove or disprove plaintiff's case, there are surely innumerable cases where this is done. Thus take the trader who applies to the Railway Commissioners for a lower rate and is entitled to call upon the Railway Co. (defendant) to prove that the rate is a reasonable one. Or take the case of the law in regard to receivers of stolen goods, where the obligation of accounting for the possession is thrown upon the supposed receiver (defendant). Or the case of the publican who as defendant has to show justification for serving men who may be drunk, rather than placing the onus of proof on the police. Or again the applicant for revocation ought to have the same means of discovery as any plaintiff in a Chancery suit, viz., by interrogatories.

It is of the utmost importance that a small amending Act be passed whereby the onus of proof of working is again put on the patentee. When this has been done we shall revert to the condition of things that was contemplated by Mr. Lloyd George in his Act of 1907.

In my advocacy I am primarily concerned for what I regard as the benefit of the State, which ultimately means all of us. I should like us to revert in fact to the original Patent Act, the Statute of Monopolies. My principal object, I confess, is to do all I can to stop what has been going on so long on a very large scale, i.e., Germans taking patents here to prevent manufacture here, working them abroad however, we thus creating a protected market for them there, at our expense, fostering their industries and damaging ours.

It should not be enough that part of the invention should be worked here but the whole of it. Thus did the Comptroller-General decide in an action for revocation, I think, in 1909. The importance of insisting on this will be apparent to all who have had close knowledge of what happened at the outbreak of the war, when one of the difficulties was not so much the production of certain patented products but the impossibility of obtaining certain intermediate substances necessary for the manufacture of the former.

I hope I have made it clear that those of us who advocate revocation do so not because we desire to destroy the patent but solely to enable us to use the threat of revocation of British patents worked abroad but not here.

Had we really insisted on this years ago in the case of chemical patents we should to-day have an organic chemical industry rivalling that of Germany. I dispute absolutely that it is primarily a question of education. If the patent law had been what the Associated Chambers of Commerce have asked for two or more decades ago there would have been plenty of suitably trained English chemists to carry on. A demand creates a supply. With a big demand for these chemists the Universities and higher Technical Colleges would have trained chemists not only as capable and brilliant as they have in the past, but in numbers fully adequate for the requirements of the industry.

Mr. A. G. BLOXAM said that Dr. Rée not only wanted to alter the Patent Laws but also to

abolish the principle of free trade. Both Germany and Austria had altered their patent laws in a manner that was retaliatory. As regards retaliation, he mentioned that very shortly after the Patent Act of 1907 had been passed, the patent laws of Germany and Austria had been altered as regards compulsory working, to make the law correspond with our 1907 Act. The effect was that German patents granted to foreigners would be revoked if the process were worked mainly abroad.

Dr. Rée said that the German system of compulsory working had been originally even more severe than ours.

Mr. J. W. HINCHLEY said that in taking out a patent you were practically giving your business away. The State got the benefit entirely; the man who worked out the process was not protected. It was time they had special rights for inventors. Recently some special secret methods had been sold for large sums of money; if those methods had been patented they would have become known, and could not have had the same value. He thought that some State action other than Patent Law was desirable in the case of inventors.

ECONOMY OF ACIDS IN METAL TRADES.*

BY E. KILBURN SCOTT, A.M.I.N.S.T.C.E., M.I.N.S.T.E.E.

PART I.—NITRE CAKE INSTEAD OF ACID.

The acids used in the metal trades are sulphuric acid and hydrochloric acid; *aqua fortis*, a mixture of sulphuric and nitric acids; and also, since the war, a solution of nitre cake sometimes called "sulphate acid."

Sulphuric acid may be divided into rectified sulphuric (R.O.V.) or white acid, and brown sulphuric or B.O.V. At one time a good deal of rectified acid was used for pickling, especially for cartridge metal and copper, but it is now practically all absorbed for explosives supplies. Brown sulphuric acid is still obtainable for pickling purposes, but only in limited quantity. Hydrochloric acid is principally employed for the hollow-ware and galvanised iron trades, but some makers of steel tubes also use it.

Aqua fortis is for "dipping" brass articles, and is usually made up of 6 parts crude sulphuric acid, 2 parts crude nitric acid, and 4 parts of water.

After losing its strength slightly, the *aqua fortis* is used as a second bath (fiss) to which a little salt may be added. It finally becomes ordinary pickle.

Nitre cake is a waste product from the manufacture of nitric acid and consists principally of acid sodium sulphate. It is produced in very large quantities in the numerous plants which have been erected or extended since the war, for making nitric acid for explosives.

As obtained from nitric acid manufacture it usually contains 30% of free sulphuric acid, but may have 35% or even more. It generally also contains 1% to 2% of nitric acid. A second source of nitre cake is from sulphuric acid manufacture, and in this case the cake may contain 20% to 30% of free sulphuric acid.

It is important to note that nitre cake varies and even that made by any one firm may vary from time to time. Most of it now consists of a mixture of acid sodium sulphate and sodium sulphate. It is not all acid sodium sulphate as used to be the case when plenty of acid was available, because the Government insists on a minimum of sulphuric acid being used in the manufacture of nitric acid.

* Taken as read.

Analysis of nitre cake made by a north country firm gave:—

Sulphuric acid	31.56
Sodium sulphate	63.99
Moisture	3.85
Iron and aluminium oxides	0.137
Magnesium oxide	0.190
Insoluble	0.365
Calcium oxide and chlorides	Traces

The amount of moisture depends on how long the cake has been exposed to weather. When freshly made there is no moisture, but when it has been standing a few weeks, even if under cover, the moisture may be several per cent. It is advisable to use nitre cake as soon as possible after it is made.

At one time nearly all nitre cake was either dumped on to vacant land or into the sea. A considerable amount is now utilised, however, especially that made in factories near to industrial centres.

Uses for nitre cake. Before the war, practically the only uses for nitre cake were for making hydrochloric acid, Glauber salts, and salt cake; a small amount was also sold to manure manufacturers, and to glass works.

It has now many uses, *e.g.*, in the textile trades it is used for:—Extraction of grease from wool suds; extraction of grease from piece scouring suds; refining of grease; stripping colour from rags, for making shoddy; removing cotton from mixed fabrics for shoddy; dyeing rags in the shoddy trade, etc. It is also used for calico bleaching, in the mineral water industry, and for paper making.

Nitre cake had been tried in the manufacture of sulphate of ammonia, one sample giving:—

Ammonia	24.01
Free acid	0.88
Moisture	2.70
Sodium sulphate	3.20

which corresponds to a consumption of over 7% of nitre cake, equal to about 2½% of acid saved.

The Sulphate of Ammonia Association recommends that the percentage of nitric acid in the cake should not exceed 0.05%, and the amount of nitre cake should not exceed 10% by weight of the acid used.

The cake is dissolved in water until the solution shows 100° Tw. (sp. gr. 1.5) at 200° F. and the mother liquor from the saturator, used for dissolving, is run into the saturator as hot as possible, and continuously with the acid.

Handling. When freshly made, nitre cake is fairly easy to handle, but when wet and soggy it is inconvenient. It acts injuriously on wood and attacks the iron work of carts and trucks, and as a consequence, ordinary railway rolling stock may not be used for conveying it.

When stored for any length of time, it should be kept under cover, for if rain falls on it, the acid drainage will do damage to foundations, etc. A suitable floor for a storage room is asphalt or else stone flagging with joints asphalted. The floor should be sloped and provided with a catch pit, so that drainage acid can be collected and used for making solutions or sold as sulphate acid.

A point to note is that when a warm solution of nitre cake is run into earboys there is danger of the earboy breaking when sodium sulphate crystallises out.

Nitre cake is injurious to cloth, and therefore where it has to be handled by workmen, their clothes must be protected by sacking and they should wear wooden clogs. For protection of the hands, pieces of sacking may be used, and the skin kept well greased, but the best protection are rubber mits made for the purpose by St. Helens Cable Co., Ltd.

Dissolving nitre cake. The use of nitre cake with which this paper is particularly concerned,

is in connection with metal trades, and the following notes on various ways of preparing the solution may be of interest.

One method is to use a separate bosh, preferably at a higher level than the usual pickling boshes, so that the solution can gravitate down. The water in the bosh must be heated by a steam pipe along the bottom, or by blowing steam in at the end; the hotter the water the quicker the cake dissolves.

Nitre cake can be thrown into the bosh, as received from the suppliers, but it dissolves much more quickly when broken into small pieces by a spiked hammer.

The solution in the pickling bosh must always be kept hot, so as to prevent deposition of crystals of sodium sulphate on the work. This is more especially the case if the articles to be pickled are cold.

If, after the solution has been prepared, it is allowed to cool (as for example during a week-end), sodium sulphate crystals will separate. They should be shovelled out before starting work again.

A great deal of the trouble which has been experienced with nitre cake has been due to users not knowing how to get rid of the sodium sulphate crystals. As mentioned above, commercial nitre cake of to-day is not simply acid sodium sulphate but is a mixture of that with the neutral salt, sodium sulphate. The latter can be got rid of by making a solution in a tank at a temperature of about 60° Cent., and then letting it cool to about 30° Cent. The sodium sulphate crystallises out and the solution containing the acid is then drawn off from the top. This makes quite a good substitute for brown sulphuric acid.

The crystals of sodium sulphate can be washed, after having been moved from the tank, to get rid of the small amount of acid, and this slightly acid liquor then used to make the solution of the next bath.

For pickling brass the solution of nitre cake should show about 5% of sulphuric acid on titration. Below 3% is too weak and over 7% is unnecessarily strong.

To keep the pickle up to strength, supplies of solution are added as required. If the bosh is long enough, a portion may be partitioned off at one end with perforated boards and fresh cake placed therein.

Another method of preparing the solution is to fill barrels with nitre cake and allow water to dribble through. By filling with cake and water over night, a supply of strong solution is ready by morning.

In Yorkshire it is the custom to make a hot solution in wooden tanks by steam. Equal weights of nitre cake and water give an acid strength about one-sixth that of brown sulphuric acid. The solution is raised to an upper tank by an ejector made of antimonial lead, the ejector being placed below the level of the solution so as to remain charged.

Another method of dissolving the cake is to have a long sloping trough fitted with baffles. The cake, in small pieces, is placed in the trough and then water flowing down gradually dissolves the cake.

A tank suitable for dissolving 10 or 12 tons of nitre cake per day may be 20 ft. by 10 ft. by 4½ ft. deep, and if arranged above ground is built of 3-inch planks tongued and the joints pulled together by bolts ¾-inch diameter; 10-lb. lead makes a suitable lining. Two feet from the bottom there should be a platform made of wood slats each 4 inches wide by 1½ in. thick, and 1½ in. apart. Large pieces of nitre cake can be thrown on to such a platform, and water is then run in, until the pieces are submerged. A steam pipe coil arranged along the bottom heats the water, and the cake should dissolve in a few hours. A steam supply should be fitted to the delivery pipe, so as to dissolve crystals that may form in it and stop the pipe, when the solution gets cold.

It is convenient to have two such tanks, on brick piers 4 ft. high, leaving a space between, for the delivery wagon. One tank is being filled and the nitre cake dissolved in it whilst solution is being drawn from the other.

One firm in Birmingham has built tanks for dissolving a canal boat load (30 tons) at a time. The tanks are at the side of the canal with the top at about ground level. The walls are of acid-proof brick, lined with lead, and a wooden platform is provided as described above. Cake is tipped straight on to the platform from barrows.

Strength of solution. If a gallon of water (10 lb.) is used to dissolve 10 lb. of nitre cake containing 30% of free sulphuric acid, it gives $1\frac{1}{2}$ gallons of solution containing about 22% of acid. To make a 7% solution $2\frac{3}{4}$ gallons of water must be added. Therefore 1000 lb. or, say, $\frac{1}{2}$ ton of nitre cake should give 400 gallons of 7% pickling solution.

Calculating on the basis of pure sulphuric acid, the acid in nitre cake is purchased at a lower price, but on the other hand more handling has to be done, so the labour cost is greater.

Assuming the price of nitre cake at £1 a ton, as against, say, £7 for sulphuric acid, then according to results obtained with tubes, 3 tons or £3 worth of nitre cake will do as much as £7 worth of sulphuric acid. This gives a saving of £4 for a given amount of work, but from this must be deducted the extra cost of labour.

In normal times it is doubtful if there will be any advantage in using nitre cake, but perhaps by the time things become normal again, up-to-date means of making nitric acid from atmospheric nitrogen will have been adopted. Although nitre cake is now made use of, it is only by great waste of money that it is produced at all.

Method of using. When nitre cake was first tried in the metal trades one heard many complaints about it not being suitable, and so on. Many of these were, however, due to the cake not being used properly. Some tried to dissolve it cold. Others who did employ heat, had trouble with the sodium sulphate crystals, found on Monday morning after the solution had cooled, and they failed to remove them before starting work.

On one occasion a workman who offered objections to using nitre cake, was found to have tested the solution with a hydrometer, and consequently had made the pickle too weak.

The extra viscosity of nitre cake solution makes it less suitable for tubes and for articles which have small holes. Viscosity can be reduced by using a higher temperature, but then there is trouble with steam and fumes.

An interesting fact which came to my notice, was that the surface of tubes and malleable iron castings had a bright bluish tinge after pickling with nitre cake solution, whereas they quickly went rusty after pickling with brown sulphuric acid. The manager said he preferred nitre cake to brown acid.

No doubt impurities in nitre cake account for the results in some cases being different from others. The nitric acid which some cake contains, is certainly advantageous for pickling brass and copper.

For removing borax from brazed tubes nitre cake solution is not very effective, as shown by Mr. Dugard's tests: Tube No. 1, tested in brown vitriol 10% solution for 5 mins.; the borax was quite removed. Tube No. 2, tested in brown vitriol 5% and sulphate acid 20% for 20 mins.; the borax was removed. Tube No. 3, tested in brown vitriol 2½% and sulphate acid 20% for 20 mins.; the borax was not quite removed and the tube was dirty inside. Tube No. 4, tested in sulphate acid 20% solution for 50 mins.; the borax was not removed, and the tube was dirty inside.

For pickling iron and steel it would appear that arsenic is some advantage, e.g., certain firms use arsenious oxide as a "restrainer," for the purpose of checking the action of acid on the steel, after removal of scale. The manager of a tube-making firm in Birmingham informed me that he had used it for some years, because it prevented penetration into the steel, and reduced fumes.

The arsenious oxide used is what is known as "white arsenic," produced in the first stage of extraction. It is sold in the form of a powder, and about one pound is used to each gallon of acid.

Arsenic is objectionable to some industries, for example, it would not do for pickling cartridge metal or for galvanising and tinning.

A large proportion of the nitre cake made in the Birmingham and Wolverhampton districts is sent to tinplate works in South Wales. Makers there were amongst the first to use nitre cake on a large scale.

PART II.—OTHER METHODS OF SAVING ACID.

Although a good deal has been said regarding uses of nitre cake, I am not at all in sympathy with the policy of certain parties, of forcing it "willy nilly" on to all kinds of manufactures. Nitre cake does not suit many small firms and industries.

Considerable economies in acid can also be made in other ways, some of which are more effective than using nitre cake, because they are in the direction of reducing the acid or dispensing with it altogether.

The shortage of acid and the high price has had a beneficial effect on Birmingham metal trades, because manufacturers have learnt to do with less acid, and in some cases to dispense with it. When the war is over, the economical methods will be retained.

Much acid was formerly used for pickling the scale from brass stampings, but many firms now find they can do without the acid. It was also used to pickle hard scale from forgings and castings, so as to make them easier to machine. The extra hard steel now available for tools cuts much better. Cutting is also eased by leaving more metal on so that the point of the tool can get well below the hard scale.

Regarding *aqua fortis*, it is of interest to note that employers who have been accustomed to leave everything to the "dippers" have on investigation been able to reduce consumption considerably, in some cases by a half.

In the ordinary Birmingham brass trade many articles are "dipped" in *aqua fortis* which might just as well remain in the condition in which they leave the foundry and stamping shop. Where appearance is of great importance they might very well be painted or lacquered. Many munitions parts are "dipped," which would be better without it. Even when parts are "dipped" they are often stored so long that they become discoloured. In fact buttons, buckles, and Webb equipment fittings are sometimes made dull, so as not to be conspicuous and reflect light.

I know one firm which used over 36 carboys of *aqua fortis* per week for dipping military buttons and ornaments. Another firm doing exactly the same work have managed to dispense with the use of *aqua fortis* altogether, by barrelling. The scouring barrel is filled with granite chips and water, the burnishing barrel contains steel bicycle balls and Hudson's dry soap and water, and the "drying out" barrel contains beech sawdust.

One firm employed in making steel conduit uses a long steel barrel for cleaning scale from fire-welded steel tubes. The tubes are rumble round along with leather "mosings" and in about half an hour are sufficiently clean for the enamelling process.

Considering how much quicker and more effective is hot pickle than cold pickle, it is surprising to find so many firms in Birmingham using the latter. It is partly due to steam not being available. Gas jets can be easily applied under a bath, and one manager who did this assured me that his consumption of acid had been considerably reduced. A bath geyser might be used for the purpose.

Quick quenching removes scale very easily, and for this reason pickling boshes should be close to the muffles. In some of the older works the boshes are at a considerable distance away, which gives longer time for cooling, and formation of scale.

Spent pickle. The practice of running spent pickle down the drains, which in some factories is done every 24 hours, causes great waste of acid and of the metals dissolved. Spent acids also may be a disadvantage to the system of treating sewage.

To show what can be done by being alive to the problem, the case of a firm making rifle ammunition cartridges may be cited. Before the war they used sulphuric acid pickle of about 6% strength and the spent pickle was wasted. To-day the method is to use pickle of 6% only after the first annealing, as there is more scale at first, due to the greater bulk of metal. For the following annealings pickle of only one-sixth the strength is enough.

The metal passes through automatic muffles and the hot metal falls direct into concrete vats lined with lead, containing pickle of only one per cent. strength. As a result, the acid now used for a given amount of work is only about one-third. The pickle is continuously circulated through an overhead tank where it is regenerated by addition of new acid. The pickle is cooled in the process, and no doubt the quick quenching which results helps to save acid.

There appears to be a good opening for a central recovery plant to treat spent pickle which could be collected from various firms. The corporation of Birmingham and the Chamber of Commerce might usefully consider this question.

The metal taken by "spent pickle" down the drains amounts to an enormous figure. Even where the metal to be pickled is copper, few firms take the trouble to recover the dissolved metal. It is well worth while.

Deposition of copper on iron has been employed, but it is hardly suitable because the amount of metal is so small as compared with the amount of liquor that most of it may be washed away.

The most promising way is to treat the spent pickle with lime. This first neutralises the acid and forms calcium sulphate and water and then the lime reacts with the copper sulphate again to form calcium sulphate, the copper going to make a rich slime or mud which is easily removed for treatment.

The liquors which go into drains from large firms contain a considerable amount of metal in mechanical suspension. This can be removed by a Frue Vanner machine as used in gold mining.

Even commoner metals may be worth recovering; for example, in the pickling of hollow-ware over 50 lb. of metal is lost for every ton of articles pickled. The sheets now used for hollow-ware are either close annealed sheets or open sheets, direct from the rolls, and the loss is about 60 lb. per ton according to the conditions of surface. When metal is pickled, the loss is not only that represented by removal of scale but is also the loss of metallic iron dissolved away by the acid.

Hydrochloric acid. The acid for pickling hollow-ware is hydrochloric acid, and it may be of interest to add that the amount used by Birmingham firms, namely, 1½ to 2½ carboys per ton of metal ware, is very much in excess of what is used originally to pickle the sheets from which the hollow-ware is made. South Wales makers use

much less, which may be due to mechanical means taken to agitate the work.

Movement of the work, or of the pickle, or both, expedites any pickling process and saves acid. An ideal way is to have the pickle continuously circulating through the boshes, and this is done by several firms.

Owing to the high price of spelter, various other methods of treating hollow-ware have been introduced, for example aluminium paint and black japan. Although to be satisfactorily watertight, buckets should be galvanised, the Army Contracts Department now accepts buckets which are painted.

Hydrochloric acid is used by one of the most important firms in Birmingham district making high-class steel tubes. They say they prefer this acid because it does not act so quickly and attacks the steel less than sulphuric acid. The acid is also used cold, and this ensures that all the tubes are acted upon equally. When a bosh is heated by steam passing through a pipe, the nearest tubes are acted on more vigorously.

Another advantage is that boshes for hydrochloric acid do not require to be lined with lead. One type of bosh which works well is 16 ft. by 2 ft. by 1½ ft. and built up of 3-inch planks cramped together between posts, driven into the ground. No bolts are used. The bosh is lined with boards 1½ in. thick, and a mixture of pitch and tar run in between the boards and the planks.

Sand-blasting. Considerable economy of acid is possible by sand-blasting, especially where hard scale surfaces of forgings and the burnt sand of castings have to be removed. A sand-blast plant comprises the blasting mechanism, air compressor and receiver, and exhaustor for returning the abrasive for use again. The abrasive is fed through a slot controlled by a valve, and is caught by the current of air and driven through the discharge nozzle. The air pressure is about 10 lb. per square inch. For cleaning scale and core sand from iron, steel, or brass castings, chilled iron shot is used.

A room sand-blast plant has a glass roof with ventilators, and perforated steel grid floor. The abrasive falls through the grids into a hopper from whence it is drawn by an exhaustor to the top of the sand-blast apparatus. An exhaustor fan changes the contents of the room four times a minute. A cyclone separator separates the dust and fine core sand, leaving the abrasive and heavy core sand. The operator works inside the room, directing the blast nozzle by hand, and he is provided with a helmet, as protection from rebounding abrasive.

A barrel sand-blast plant consists of a rotating cylinder supported at its circumference on rollers. Small castings or forgings to be treated are placed in the barrel and the abrasive directed through the ends of the cylinder against the articles. A slow rotary movement causes the castings, etc., to tumble over one another, thus bringing new faces under the action of the abrasive.

For a chamber sand-blast plant the operator stands outside the chamber, and passing his arms through suitable openings, directs the blast on to the articles to be cleaned. He observes the operation through a window. This plant is used for cleaning brazed joints of cycle frames, handlebars, and casements.

A sand-blast machine for cleaning shells has a fixed vertical blast, the shell being supported over it by a ball and socket joint. The shell can thus be turned round and rocked sideways in order that the abrasive may reach all the interior. Formerly it was the custom to remove scale from shell blanks with acid, and also to use acid for cleaning the inside of the machined shells before varnishing. It has been found, however, that acid enters the pores and by oozing out afterwards is detrimental.

A firm in Birmingham making reflectors used to employ a large amount of acid for pickling the scale from small forgings. Now they do not use any acid because the work is done by sand-blast machines.

Electro pickling. Although electro pickling has been successfully employed abroad, it does not succeed in this country. One method of pickling employs direct current and the electrical action is much the same as that which takes place in an ordinary plating bath, the scale being split off mechanically by formation of gas beneath.

The other method employs alternating current; the current flows rapidly in each direction according to the periodicity of the circuit. It might be thought there would be little effect and yet there is. It is probable that the amount of scale removed per unit of energy is as much with alternating current as with direct current.

One pickling bosh in which alternating current is used measures 4 ft. long by 2 ft. square. It is made of planks, and rests on four ordinary drain pipes filled with cement, which act as insulators. Electrodes of sheet iron 2 ft. sq. and $\frac{1}{4}$ in. thick are fixed at each end.

The electrolyte—hydrochloric acid, salt, and water—has an acidity of about one per cent. Alternating current is supplied at 15 volts and 50 periods per second by a small motor generator. When reflectors are being pickled, they are placed in a wooden crate between the electrodes, so that the liquid can circulate freely between. During one test 14 shades each 18 inches diameter and 2 $\frac{1}{2}$ lb. weight took 210 amps., at 14 volts, or just under 3 kilowatts for 10 minutes. At $\frac{1}{4}$ d. a unit, the cost of electric energy was therefore about $\frac{1}{4}$ d.

Clean annealing. In going around various factories I have remarked on the many varieties of annealing furnaces in use, and the extravagant claims put forward, especially for those which happen to be home made. As a matter of fact nearly all are bad.

Where an ordinary coal-fired muffle and a Bonecourt muffle were working side by side, a test of the loss in annealing and cleaning copper gave 0.74% loss for the ordinary coal-fired muffle, and 0.18% loss for the Bonecourt muffle.

Several attempts have been made to anneal in a neutral atmosphere to prevent oxide being formed and one non-sealing muffle which has been successfully applied to non-ferrous metals is that of Bates and Peard.

It consists of an air-tight annealing chamber the openings to which are sealed by water. The annealing chamber is fired by gas, oil fuel, or coal, as is most convenient. The metal is conveyed by an endless chain belt, being first drawn through one water seal, then through the hot part of the chamber, and out through the other seal.

In the Birmingham district, a Bates and Peard muffle is used for annealing small brass articles, and another for copper sheets. High resistance wires and copper wire are also being annealed by this type of muffle.

The Vaughan Hughes muffle for non-ferrous metal works in a somewhat similar way to the above, and several are in use in the Birmingham district. It is sealed with water, and the annealing chamber is kept filled with superheated steam.

Rolls of copper and brass strips may be close-annealed with little or no sealing by placing them in steel pans and luting in with wet clay. When in the annealing furnace the moisture in the clay is made into steam and then the metal is in a non-sealing atmosphere. When ready, the pans are quickly withdrawn and placed under water.

The annealing furnace of Metalloids, Ltd., uses an atmosphere of purified producer gas, and does more than others, in that it reduces any oxide

that may be present. The process consists in passing the articles to be annealed through a heated muffle and a cooling chamber in both of which there is an atmosphere of specially purified producer gas. The hydrogen present in the gas acts on the oxide and reduces it to iron, steam being also formed.

Electric muffles. Electrically heated muffles present so many important advantages over any others that they are bound to come to the front for special work. At a future date I hope to have something to say about them, but may mention now that I have seen steel tubes come out of a new type of electric muffle as bright as a sword blade although they had undergone a temperature of over 800 °C.

J. Walter, of the Gas Research Department, Birmingham, has developed a water seal for an electric muffle by which steel articles can be heat-treated without sealing and plunged directly into water at the right temperature. The muffle tube is arranged vertically and its lower end projects into a water bath.

The articles to be heated are suspended by a wire in the hottest part of the muffle tube which is filled with coal gas to prevent sealing. When the correct temperature is reached the wire is released and the articles fall into the water.

ANNUAL DINNER.

The Annual Dinner of the Society was held in the Grand Hotel on Thursday evening, over 150 members attending.

The toast of "The King" was proposed by the President, Dr. Carpenter, and the toast of "The Society of Chemical Industry" by Dr. R. S. Morrell, the President responding. Prof. H. Louis proposed "The Birmingham and Midland Section," response being made by Mr. E. W. Smith and Mr. F. R. O'Shaughnessy.

FRIDAY MORNING.

SCHEMES FOR CO-OPERATIVE INDUSTRIAL RESEARCH.

BY HERBERT W. ROWELL.

[ABSTRACT.]

Co-operative research is entirely unknown in Britain, while it has been established for several years with considerable success in other countries.

The schemes suggested below are put forward as outlines which might profitably be considered by groups of manufacturers, and the essential points considered are:—

(1) That a properly equipped laboratory and experimental station should be established on such a scale that it could afford to employ experienced industrial research men of high grade to organise and supervise the research and experiments.

(2) That the manufacturer may safely entrust all the details of his processes to the organisation without risk to business interests.

(3) That discoveries made should be the property of the manufacturers initiating and bearing the cost of the experiments.

(4) That the cost of experiments should be decidedly less than if the manufacturer had employed his own staff and laboratory and that the probability of success should be greater.

A group of manufacturers of, say, sulphuric acid, tar products, or pig iron would pool investigation into raw material, methods of manufacture, improved products, disposal of by-products, outside competition, and so forth for their common

good. A full-sized factory could be run in connection with the laboratory to provide exact working data and efficiency methods and help pay the cost of research.

In future it must be British industry against foreign competition instead of a single manufacturer against his home industry and the world in general, and this involves buying and selling agreements and other safeguards which are arranged in other countries, and can be arranged here, and it certainly involves more efficient employment of capital, material, and labour, and eventually means more profits and lower prices.

At the other end of the scale we have something on the lines of the Mellon Institute in Pittsburgh. This scheme practically amounts to a consulting chemists' laboratory on a very large scale (and such exist in the United States) and therefore on more successful lines. A fairly large program of circumscribed dimensions must be definitely laid down, and there are other drawbacks which make the value of the scheme doubtful to a small works.

There is no doubt that the first scheme of co-operation throughout a trade is the most profitable to all concerned, but there seems to be no probability of the British manufacturers combining in this wholesale way for many years to come.

Something less ambitious, organised in such a way that it can be developed into the full scheme as progress is demonstrated, seems to meet our present state. The tar trade may be taken as the first example, for it seems to be faced with both a commercial and technical revolution after the war. Coke ovens and large gas plants are partly refining their own products in competition with the tar distiller.

Methods of distilling and fractionating are altering and require alteration, and the products of distillation will have to be marketed in a different state of purity and the values of tar products—never very stable—are likely to be altered considerably.

If the tar distillers can have commercial agreements as to raw materials, sulphate of ammonia, and creosote, why not in standard tests and products and in research and development of the trade?

The tar producers and distillers could subscribe, say in proportion to their capital or turnover, to constitute a central laboratory and experimental works, while control testing and efficiency of existing plant would remain a matter for the attention of the individual works. This laboratory could have two functions, one an analytical department for devising specifications and standard methods of analysis and acting as a referee laboratory for the trade, and the other a research department with an experimental works and staff of chemical engineers attached to it.

If a research department could make pitch equal to natural bitumen, tar oils into fuel, and lubricant equal to petroleum oils, or discover a use for creosote oil equal to the present demand for timber preservation—and these things are by no means impossible—it would cover its cost many times over.

Other matters of a non-competitive nature which might be taken up are the carriage of dangerous goods, better and cheaper packages, safety measures against fire, explosion, and industrial disease, and fuel economy.

The quantities and value of the coke, gas, and so-called by-products can be greatly modified by alteration in the method of working as well as in the design of apparatus, and as coke ovens, gas plants and recovery plants are usually in charge of an engineer, the chemical aspect of the problem does not get full consideration. A coke-oven plant would call upon the research organisation to enquire into the efficiency of all or part of its plant or have experiments made on a more suitable

type for its particular class of coal. The tar distiller could have his tar supplies tested on a works scale and be advised of a better plan of working them to obtain a more profitable fractionation. There are great possibilities in this which cannot be shown on a small scale laboratory test. The distillers in general could have experiments made in washing and purification of the various products, and the numerous problems of fractionation, distillation, and filtration which trouble the works could be solved on practical lines for the mutual benefit of the subscribers.

As a second example we may take the iron trade. The steel industry has received special and successful attention in this country during the last decade, but the smelting and casting of iron is still done in the same way and in many cases by the same plant which was antiquated 20 years ago.

Ideas for new types of plant have been imported from America in a few cases, while the Americans have developed dry blast, fuel economy, rapid working, slag cement, and the working of low-grade ores by the liberal application of research.

A combination of iron masters, foundry men, and mild steel makers, quite apart from the remainder of the steel trade, could profitably institute a research organisation to standardise pig iron grades and foundry mixings in the first place and then develop improved smelting methods, more economical charges, heat treatments, foundry methods, and iron and mild steel foundry mixings for standard purposes.

If such an organisation could make blast furnace slag worth a shilling a ton or reduce production costs by a shilling per ton of pig, its existence would be very amply justified.

As the last example, we might take the large number of works in the Birmingham district—mostly small concerns—which melt, cast, roll, stamp, and otherwise work alloys of copper, zinc, tin, nickel, lead, and other non-ferrous metals. Practically none of these works employs a chemist or metallurgist because of the comparative cost, yet they all feel the need of expert advice.

Except for certain mysterious dopes which are added to meltings—often without practical effect—some foundry methods, and a few very special alloys, which can easily be analysed, there are no secrets in the trade and business interests would not be adversely affected by the institution of a co-operative laboratory.

Quite a modest affair could be started for analytical work and general advice on technical problems but designed to expand into a full research department and experimental works where fuel consumption and furnace design, crucibles, heat treatment of castings, casting methods, micro-structure, rolling and stamping and finishing problems could be solved.

SOME PRINCIPLES OF INDUSTRIAL RESEARCH ORGANISATION.

BY HERBERT W. ROWELL.

[ABSTRACT.]

Industrial research covers a wide range of scientific activity, from chemical and physical work in the laboratory and experimental department, to the lay-out and design of plant, and to the final details of economic production.

The only fit person to undertake the control of research and the development of industrial technique is the scientifically trained chemist, engineer, or physicist, as the nature of the work demands, because he has the best mental equipment and method for discovering the true cause lying behind an observed effect or for combining causes to produce a desired effect.

All matters of research and experiment in an industrial organisation should be centralised to one laboratory under the control of one person, even if the organisation is interested in various types of manufacture in separate works. The laboratory should be as liberally equipped as finances will allow, and should include floor space and machinery sufficient to carry out experiments on something approaching a works scale. In large organisations this should include a unit experimental factory, and in small organisations the experimental floor may profitably be used for the manufacture of small lines required as raw material for various works operations, or for direct sale where the bulk of output is small and skilled supervision is required, without interfering with the experimental value of the room to the research department.

The initiation, organisation, and carrying through of all research and experiments up to the experimental works stage, should be in sole charge of a trained chemist or physicist, with works experience, responsible directly to the executive. Research and experimental work should not be under the direct control of the works, but the research department should depend almost entirely on the advice of the works managers in matters of existing methods and troubles in manufacture, and to a great extent on what matters require investigation.

While the initiation of research should lie principally with the head of the research department, there should be some safeguard for giving credit for ideas and improvements to those who originate them. Suggestion bureaux for works employees and direct report to the executive in the case of management staff are used by a number of firms.

Wherever possible the results of research should be covered by patent rights, and where the publication of discoveries, methods of analysis, and similar matter does not seriously damage commercial interests, the results should be contributed to the common stock of scientific knowledge. Every distinct item of research should be properly planned, and all available information on the subject collected, and properly indexed, and digested, before starting practical work, although re-planning will probably be necessary as the work proceeds. The cost of work should be estimated where possible, or a definite sum allotted to the work by the executive for experimental plant and laboratory expenses.

No experimental work should be done in the manufacturing departments except such as is required in starting a new machine, or process, after working on a smaller scale in the experimental departments, or such as is required in enlarging the production of a machine or process without alteration of the principle on which it operates. Loss of production and leakage of information are usually more costly than a special experimental machine.

DISCUSSION.

Mr. B. F. HOWARD said that the author had stated that co-operative research was entirely unknown in Britain; but how did he know whether or not every piece of research which was done was not co-operative? There was no means of knowing how the results of research were utilised. He also put forward the view of buying and selling agreements as if that was something new. There again how did the author know what buying and selling agreements there were? These things were not published; they would lose their point if they were. He submitted that this principle of co-operative buying and selling went on to an enormous extent throughout the chemical industry. There was also a tendency in the paper to assume that manufacturers

had never had any technical education. It was also assumed that the works chemist was a genius and the members of the Board were absolutely ignorant of all chemical problems. He considered that statement too sweeping, although it was possibly true in some cases.

Mr. E. W. SMITH pointed out that there was a considerable amount of co-operative research work going on in this country. The brass industry in Birmingham was particularly mentioned by the author. There was an extensive metallurgical research laboratory run by the Corporation to which a very large proportion of the brass casters in the city came with their problems. The results of that research were of general value. The work that was being done was entirely co-operative and fulfilled all the conditions Mr. Rowell had laid down. Surely it was known that for many years a considerable amount of co-operative research had been going on in connection with the gas industry. The Institution of Gas Engineers had its Committees working in conjunction with municipal authorities, and chemists had been engaged for years on technical research work, the results of which had been available to the whole industry.

Dr. C. A. KEANE said that the system of Industrial Research Fellowships at the Mellon Institute had been very successful. Dr. Bacon had informed him that during 1916 the contributions had doubled, and they had over 80 men engaged in industrial research work at the Institute. They were not altogether without knowledge of such organisations in this country. Experiments were being made in more than one institution on somewhat similar lines to the Industrial Fellowship system of Pittsburgh. Every encouragement should be given to such efforts. Some manufacturers' associations were already interested in the work at Pittsburgh, and in one case an application had been made for details of the scheme. The Industrial Fellowship scheme had shown one way, he did not say it was the only way, in which the Universities could be utilised. They could ask manufacturers, and especially the small manufacturers, whether there were not problems which they could submit to educational institutions. The terms were not difficult to arrange, so as to protect the manufacturer and also the institution. But it was fundamental to recognise that the men in charge of these institutions were honourable men to whom confidence could be given and to whom also authority could be given. The experience of the war had shown that academic chemists were capable of being trusted and doing work of considerable national importance. One of the great difficulties in training chemists for industrial occupations was to get in touch with the requirements of the industry itself. There had been an appalling loss of chemical efficiency owing to the system which had prevailed in the past. They had not recognised their responsibility towards younger men and the necessity for making them fit for higher and wider occupations. If by means of the schemes outlined they could lead the best demonstrators to take up industrial work it would be of very great value in the future. The association of industry with teaching institutions would undoubtedly activate the abilities of the educational chemical staff. There had been a tendency in the past for the staff to become irresponsible, and something which would endow them with an element of responsibility must be a great advantage.

Prof. W. A. BONE deprecated certain statements of the author in regard to the backwardness of the British manufacturer. For example, he said that the Americans had developed slag cement. He did not know whether the author meant that Americans were the first to develop that, because

that was not so. It had been developed in England. He had also spoken of the development of dry blasts. Dry blasts had been tried in several English works and in no case had the capital expenditure been justified by the fuel expenditure.

Mr. ROWELL, in reply, said that the American method of working dry blasts did not suit the English practice. He knew dry blasts had been worked in this country but he did not say it would pay in every case here. It had not paid in every case in America. He agreed with Dr. Keane that the universities must be associated with industrial research. As to buying and selling agreements, he was urging that they must be taken up more frequently than they were now. There must be trusts in the matter of buying and selling and in connection with research. The bigger the trust was the more it could spend on research and the better would be the results obtained.

THE ARTIFICIAL SILK INDUSTRY.

BY LEONARD P. WILSON, F.C.G.I.

The material known as artificial silk, and sometimes wrongly described as imitation silk, is now in such general use for producing a large number of textile materials, that there is no doubt whatever that although the commercial production of artificial filaments is practically no older than this century, it has made for itself a permanent position in the world of industry. For artificial silk has ceased to be what it once was, only suitable for fancy goods, more ornamental than useful, and now is produced in filaments of almost unlimited length, of uniform diameter, and of any thickness from less than a thousandth to a sixteenth of an inch, possessing any desired lustre, from the most brilliant to quite dull, capable of being dyed to any shade, and of a sufficient tenacity either dry or wet, to be used in any textile operation.

There was a period of a hundred and fifty years between the time of the suggestion of the French scientist, Réaumur, that silk might be made artificially from resins or similar materials and the date of the first patent, that of the Swiss, Andemars, for the production of artificial filaments, this latter having been made possible by the discovery and investigation of cellulose nitrate. From this time, about 1885, to the end of the century, a great deal of valuable preliminary work was done both in this country and abroad, with the aim of producing artificial fibres for textile use or the production of electric lamp filaments. Of our own countrymen whose work was noteworthy at this time are Crookes, Wynne, Powell, Swinbourne, Swan, Millar, Cross, Topham and Stearn, but they did not achieve commercial production during this period; abroad, however, Comte Hilaire de Chardonnet began to manufacture artificial silk in 1891 at the rate of 100 lb. per day at Besançon, and although his success was not uninterrupted, he was producing about 1000 lb. per day before anything was made on an industrial scale in this country.

All the early artificial silk was made by the Chardonnet process (Eng. Pats. 6045 of 1885, 2211 of 1886, 5270 of 1888, etc.) or modifications of it, which had for a basis guncotton dissolved in ether-alcohol; this solution was of very high viscosity and was formed into filaments by forcing it through glass jets which had a bore of between two and ten thousandths of an inch, and which were immersed in water to remove the alcohol from the solution as it emerged, and so to form a semi-solid fibre which was picked up and together with a number of others wound on a spool. The whole machine was enclosed and warm air was passed through

it to remove the volatile solvents still held by the thread, which was thus further hardened; the ether and alcohol were condensed, and so a considerable proportion was recovered; the amount of solvent lost, however, was always very great; this and the great danger from fire were among the causes which made this process costly and undesirable. Moreover the finished thread consisted of cellulose nitrate which depreciated very much on keeping owing to decomposition and the formation of acid compounds; it was very inflammable and difficult to dye. These defects were partially overcome when the denitration process was introduced, treatment with calcium or ammonium hydrosulphide being employed to remove the greater part of the nitro groups—sufficient always remains to give a deep blue colour with diphenylamine and sulphuric acid, and to show about 0.05 to 0.15% of nitrogen on combustion. Unfortunately denitration reduced the weight of the product, together with its strength both in the dry and wet state and its extensibility. In spite of this, however, Chardonnet silk was well received because of its brilliant lustre, which was considerably greater than that of natural silk. In addition to the method already mentioned of forcing the solution into water, or "wet spinning," another known as "dry spinning" is now employed by the Chardonnet Company, the solution of high viscosity being forced through the jets into air, when the solvent rapidly volatilises and a thread is formed which can be wound upon a running bobbin. The machine employed for this process is one of the simplest used in the production of artificial silk; the nitrocellulose solution is fed through a pipe to which are fitted a number of fine glass jets, from which the liquid is drawn on to rollers or spools running at a comparatively high speed, the filaments are gathered into groups of the number required to form the composite thread before reaching the roller, and are wound on it with a backwards and forwards traverse motion to keep the threads separate. The whole machine is enclosed in a cover through which warm damp air is passed to remove the volatile solvent, which is then condensed by passing the air through a spray of amyl alcohol; the ether and ethyl alcohol of the solvent are collected in this, which is then redistilled, giving a fairly good recovery. During drying the threads become lustrous, strong and elastic; they are then twisted and wound into skeins, denitrated, and finally bleached. In addition to the factory already mentioned at Besançon, nitrocellulose silk was produced at Spreitenbach in Switzerland, Kelsterbach and Bobingen in Germany, Padua and Pavia in Italy, Obourg in Belgium, Sarvar in Hungary, and Wolston, near Rugby, in England. The last named was among the least successful, and the manufacture was continued there for only a short time and with considerable loss.

It is not uninteresting at this point to notice that those artificial silk processes which were destined to be partially or wholly replaced by one more successful, have failed more quickly in this country than on the Continent, where temporary success has often been achieved by processes which have had none here; while the method which has attained the foremost position and has largely displaced the others, has been more successful in England than abroad, although it was taken up some years earlier in France and Germany. Whether this is due to a more stringent process of selection in British industry or to better technical work in the one successful case I am not prepared to say. On the Continent nitro silk had for some years a period of great financial success, but at the beginning of this century it had to meet increased prices of raw materials and the competition of two other processes, cuprammonium and viscose,

and some of the effects of this are to be seen in the selling prices and profits of the Chardonnet Company, as follows:

	Price per 1 lb.	Dividend.
1899	18. 9d.	6 1/2
1901	—	8 1/2
1903	17s. 3d.	12 1/2
1905	—	60
1907	—	30
1909	8s. 9d.	0

A few years later the same thing was to be observed with the Vereinigte Kunstseide-Fabriken A.-G. of Elberfeld, whose dividends were:—

	Dividend.
1904	0
1906	3 1/2
1908	20
1910	10
1912	0

The one exception to this state of affairs was the Belgian factory at Tubize, which was producing with success up to the beginning of the war, and is now said to be manufacturing nitrocellulose for German military purposes. It is stated that it has been able to continue to make a profit on account of the low price at which it could obtain alcohol, and the importance of this may be gathered from the statement that in 1907 the Besançon works consumed from 4 to 5 litres of alcohol for each kilogram of artificial silk produced.

Lehner, who had learnt the Chardonnet process in the Spreitenbach factory, improved its details by several important modifications (Eng. Pats. 11,831, of 1891, 22,736 of 1892, 24,003 of 1893, etc.). Instead of a solution containing 20% of cellulose nitrate, he used 10%, and further reduced the viscosity by the addition of sulphuric acid or other mineral acids. This permitted him to reduce very much the pressure required for filtering and forcing the solution through the very fine jets from that of the 50 to 60 atmospheres as used by Chardonnet; the more dilute solution at the same time allowed the use of jets of larger bore for the same size of filaments or the production of finer filaments from the same size of jet.

Lehner patented the addition of oils, resins, and solutions of waste natural silk in acetic acid to the nitrocellulose solution, but silks having properties indicating the presence of these constituents have not been seen on the market. He, like Chardonnet, used water to coagulate the thread, and produced at his works in Switzerland as much as 2800 lb. per day.

Patents have been taken out by Du Vivier (Eng. Pats. 2570 and 2571 of 1889) who nitrates his cotton with a mixture of sulphuric acid and dry potassium nitrate and carries out the operation at the unusually high temperature of 60°–80° C.; he also adds to his nitrocellulose albumin or gelatin; this process, however, does not appear to have been carried on commercially, and the same remark applies to the numerous other methods of inventors who have attempted to produce silk from nitrocellulose.

The difficulties and defects in the processes of producing silk from nitrocellulose, led to much research after other methods and substances suitable for the production of artificial fibres, and the next process to be developed was that which made use of a solution of cellulose in ammoniacal copper oxide for spinning; a Frenchman, Despaissis, took out the first patent (Fr. Pat. 203,741) in this con-

nection in 1890, but his subsequent early death led to the lapsing of the patent and nothing further was done until Pauly took out his first patent (Ger. Pat. 98,641; Eng. Pat. 28,631 of 1897) in Germany seven years later. Then followed a long series of patents and much work in which Bronnert, Fremery, and Urban were also prominent (Eng. Pats. 20,801 of 1900, 1283 of 1905, etc.), and the processes of these workers have been the basis of manufacture by the Vereinigte Glanzstoff Fabriken A.G. of Elberfeld and its subsidiaries with factories in Germany at Oberbruch and Niedermorschweiler, St. Polten in Austria, Givet in France, and Flint in Wales. This company has been extremely successful, and for the year 1913, the last before the war, paid a dividend of 34% on a capital of seven and a half million marks.

The process employed in the factories of the Glanzstoff companies starts with cotton, and indeed it appears that all cuprammonium manufacturers find other forms of cellulose unsuitable. This cotton, generally in the form of linters, is boiled with about ten times its weight of a solution containing 0.25% of caustic soda and 0.5% of sodium carbonate for 1½ hours at a pressure of about 2½ atmospheres. The liquid is run off, the cotton is washed, hollandered, and centrifuged until it contains about its own weight of water, and then again boiled with a fresh amount of liquid of half the strength for the same time as before. The cotton is then washed with water and bleached in a weak solution of sodium hypochlorite, containing 0.1% of available chlorine; the operation takes five or six hours at the ordinary temperature; all traces of chlorine are removed by washing with thiosulphate solution followed by water. The purified cotton is again beaten for a short time in a hollander, then centrifuged until it contains less than 50% of water, when it is ready for solution. The cuprammonium solution is prepared by filling a large iron vessel with copper turnings and covering them with ammonia solution containing 14% ammonia; air is blown through the solution, which is kept at a temperature below 4° C., and in about one day the copper is dissolved.

To this solution is added a small quantity of caustic soda and, if necessary, copper sulphate to raise the copper oxide content, and 2500 pounds of it is then run into the mixer, into which has been put 500 pounds of the above-described wet purified cotton. Solution takes about six hours, and during the whole of the operations and the subsequent filtering a temperature lower than 5° C. must be maintained, otherwise copper is thrown out of solution and spinning becomes impossible.

The spinning operation is not unlike that first employed in the nitrocellulose process, in that the cellulose solution is forced through glass jets into a liquid in which coagulation takes place. As at first employed this coagulating liquid or spinning bath consisted of sulphuric acid, and a concentration of about 50% H₂SO₄ was found to be most suitable. This bath neutralised and dissolved the ammonia, and a great part of the copper went into solution in it also, the remainder being removed from the thread in subsequent operations; the copper and ammonia which accumulated in the bath were both recovered. For a number of years past, however, this spinning bath has been displaced by an alkaline solution, at first by one containing 40% of caustic soda (Eng. Pat. 21,988 of 1904), to which later various additions have been made, the most interesting, and successful of which is glucose (Eng. Pat. 27,707 of 1907); the effect of this is to reduce the copper so that it is precipitated as a reddish mud in the bath itself making it easy of recovery, and also making the filaments visible during

spinning. Before this addition the bath soon became coloured blue by the copper which went into solution, and it was difficult or impossible to detect broken filaments or other spinning defects in the bath; with the addition of this reducing agent, however, there is no such coloration and the blue filaments can be distinctly seen against a pinkish background. The spinning jets are either glass tubes of about 0.1 mm. bore attached singly by rubber connections to the main supply pipe, or sets of two to eight tubes in one piece similarly attached to the machine, or as an alternative to capillary tubes, glass caps about three quarters of an inch in diameter and about an inch in depth are made, having a flat bottom and flanged top for attachment, the bottom being perforated with ten to twenty or even more holes of about 0.1 mm. diameter; these holes are made by fusing fine wires through the glass, and then dissolving them out by means of a suitable acid. The thread as it comes from the spinning bath is wound on to large glass bobbins of about six inches diameter, and on these is immersed in acid, washed free from all traces of acid, and then dried at a temperature of about 50° to 60° C. The filaments are now in a finished condition, but before the thread can be handled it must be twisted, which is done from small wooden bobbins on to which the thread is run from the larger glass ones. A further slight bleaching is given if necessary after winding into skeins.

Linkmeyer has patented and worked several modifications of the cuprammonium process, but his methods do not differ from those described to an important extent. Thiele's processes (Eng. Pats. 8082 and 8083 of 1902) have greater differences and are more interesting; he established a small factory at Yarmouth to manufacture under his patents, but it had not the success it appeared to deserve, and ceased working about five years ago. The thread produced was considerably finer than the others which had been put upon the market and of about the same dimensions as natural silk, which on this account it closely resembled in appearance and feel, having less lustre than the coarser filaments made by other processes. On account of its interesting properties the process of manufacture may be described for comparison with that already given for the more commonly used cuprammonium methods. Egyptian cotton was used as a starting material, and 50 kilos. of this was boiled for five hours, at a pressure of two and a half atmospheres, in 500 litres of 2% caustic soda, to which a little soluble oil was added; the liquid was then run off, the cotton was washed in the boiling kier and then treated with a 1½% solution of hydrochloric acid for half an hour, again washed, and bleached for 20 minutes in a solution of sodium hypochlorite containing one gram per litre of available chlorine, again soaked in acid of half the previous strength for about three-quarters of an hour, then finally washed free from acid, and centrifuged till it contained 50% of water.

The wet cellulose was pulped in a hollander, and filter pressed, then a weight of the cake equivalent to 20 kilos. of absolute cellulose was added to 260 kilos. of a 15% solution of copper sulphate contained in the hollander, and while running, the solution was cooled by means of brine pipes to 0°C. Copper hydroxide was then precipitated on the fibres by the addition of 265 litres of a 6.5% solution of caustic soda. The fibres thus impregnated were separated by filter pressing, and the cake was dissolved in 80 litres of 0.880 ammonia in an iron vessel. The resulting solution was diluted if necessary in order that it should contain 8% of cellulose.

Before spinning the solution was kept for about four weeks at a temperature of about 15° C. The

thread was formed by forcing the cuprammonium solution through a steel jet, having apertures of 0.75 mm. diameter, into a 0.25% solution of caustic soda contained in a long funnel-shaped tube, down which the solution steadily passed; by this means the relatively thick streams of cellulose solution coming from the jet were partially set and gradually drawn out to a great fineness; at this stage the thread passed into a stronger solution of 5% caustic soda, and so on to a bobbin. The filaments were then fixed by immersion in 5% sulphuric acid, after which, while still wet, the thread was twisted and reeled; the skeins were finally soaked in 1% acid, washed, and dried at a temperature of about 40° C.; the silk needed no bleaching.

Other cuprammonium processes of some importance were those of Friedrich, Bemberg, and Crumiere which differ in details from those already described. Cuprammonium silk, although it has perhaps left its most flourishing period in the past on account of the recent competition with viscose silk, has undoubtedly at present a strong hold on the market, on account of its superiority for certain purposes. This depends on its characteristic hard glasslike lustre, useful where strong effects are required, as in laces, edgings and the like, and on the smooth rounded section of its filaments, which makes it particularly suitable for braiding or knitting.

Viscose silk, the latest of the three important forms of artificial filaments to appear on the market in quantity, is the only one which is entirely English in its origin and development. Like the other artificial silks which have been described, it is a form of cellulose, but unlike them its starting material is not cotton but wood, and as it differs from them in its beginning so it differs right through its stages of manufacture, both in processes and machinery, reactions and methods, until the final product is obtained, and this also is distinguished from the others by its greater covering power and lustre, and its greater resistance to dyeing and finishing processes, and to wear. For these reasons it is thought by some competent to judge, that although its manufacture is more complicated than the older processes, it will ultimately supplant them.

Cellulose xanthate, which forms the basis of the viscose silk process, was discovered by Cross, Bevan, and Beadle in 1892, and is formed by the interaction of cellulose, sodium hydroxide, and carbon bisulphide; when dissolved in water or dilute caustic soda it forms a golden brown thick syrup and to this the discoverers gave the name viscose on account of its high viscosity. It was perhaps unfortunate that the same name had been given about a dozen years before to one of the products of certain slime-forming bacteria, by Béchamp, but now the supplanter firmly holds the title. Viscose silk like those earlier in the field had its years of experiment and probation, and although the solution was discovered in 1892 (Eng. Pat. 8700 of 1892, Cross, Bevan and Beadle) and the first spinning process followed nearly six years later (Eng. Pat. 1020 of 1898, Stearn), while the centrifugal receiver which has been largely used for viscose silk spinning was invented in 1900 (Eng. Pat. 23,158 of 1900, Topham), it was not until 1905 that Messrs. Courtaulds erected a factory at Coventry and thread was produced commercially in this country; even then success was not immediate, and for this reason the original viscose patent was renewed for the maximum period.

An earlier start was made on the Continent, and works were established at Sydowsaue near Stettin by Fürst Henkel von Donnersmarck, at Arques les Batailles near Dieppe, Venaria near Turin, and Alost in Belgium. The first named ceased operations some years ago and the same

remark applies to a later factory at Barcelona. More recently viscose works have been put up at Emmenbrücke in Switzerland, Moscow, Pirna in Germany, and Chester near Philadelphia, while others are said to be contemplated in England, the United States, and Holland; in addition to these most of the nitro and cuprammonium factories are using viscose to replace their former processes, wholly or in part, so that viscose silk factories may now be said to number about thirty. Norwegian spruce forms the usual starting material and contains about fifty per cent. of cellulose, which is obtained in a comparatively pure form by boiling the wood, after cutting it into small pieces, in a solution of calcium bisulphite under pressure, with subsequent bleaching. The pulp is then formed into sheets in a paper machine, dried, and cut to a convenient size for handling. The formation of alkali cellulose is the next stage in the process of manufacture, and this compound is produced by steeping the sheets of pulp in a strong solution of caustic soda, of a sufficient strength to produce mercerising; the excess of soda is then removed by pressing and the alkali cellulose which is thus obtained of constant composition is ground into crumbs in a mill.

It has generally been the practice to pack these crumbs in boxes and keep them to mature, the temperature and time of maturing, together with the quality of the cellulose employed, determining the viscosity of the viscose ultimately produced. Margosches in "Die Viskose," p. 41, states that in this process the alkali has a direct action upon the cellulose, and that to obtain a proper result the reaction should be carried on at a low temperature and with exclusion of air. It has been discovered, however, that oxidation is essential to the process, and that it can be accelerated and controlled by the use of suitable oxidising agents such as sodium peroxide (Eng. Pat. 13,655 of 1914, Courtauld, Glover, and Wilson), and that the use of catalysts, such as hydroxides of iron or nickel, usefully promotes this oxidation (Eng. Pat. 14,675 of 1914, Courtauld and Wilson).

The alkali cellulose after maturing is treated with carbon bisulphide, when a cellulose sodium xanthate is formed as a brown sticky mass, which is dissolved in a dilute caustic soda solution. This xanthate has the composition $(\text{Cell})_n\text{NaS}>\text{CS}$, but hydrolysis breaks it down with successively decreasing amounts of the xanthate group, $(\text{Cell})_n\text{NaS}>\text{CS}$, $(\text{Cell})_n\text{NaS}>\text{CS}$, and so on until cellulose or cellulose hydrate is reached, and it is at an intermediate stage or "ripeness" between these two extremes that viscose is used for spinning purposes. The exact ripeness which is most satisfactory depends upon a number of factors which include the strength of the xanthate, the composition of the spinning bath, and the kind of product which is to be made. This hydrolysis takes place spontaneously under ordinary conditions and with varying rapidity according to the temperature, and as the proportion of xanthate to cellulose decreases the solubility is reduced. For this reason the solid xanthate, though soluble in water when recently made, is dissolved in dilute caustic soda, and after a series of filtering operations to remove all undissolved fibres, is ready for the spinning operation.

Stearn patented spinning baths of ammonium salts and these were used for some time; the thread produced consisted of cellulose ammonium xanthate, was soluble in water and had to be decomposed or fixed by subsequent treatment in dilute acid; also because the threads were very soft as well as soluble when freshly spun, a bath of sulphate of iron was used to give a coating of ferrous sulphide to the filaments and so prevent them from sticking together during the twisting operation.

Subsequent improvements in spinning baths were the use of mineral acid (Eng. Pat. 2529 of 1902, Stearn and Woodley), solutions of sulphuric acid and sulphates (Eng. Pat. 10,094 of 1906, Müller) the use of glucose, other sugars or organic hydroxylic compounds in a bath containing acid and sometimes salts (Eng. Pat. 21,405 of 1907 and 5595 of 1908, Courtauld and Wilson) and the use of zinc salts in acid spinning baths (Eng. Pat. 406 of 1911, Courtauld and Napper). These patents mark the stages of progress in this portion of the manufacture, but many others have been granted for special conditions of temperature and strength of solution, and an interesting set of processes originated in America with Waddell, Waite, and Ernst who used sodium bisulphite solutions for coagulating the thread.

The viscose is forced through jets into one or other of the spinning baths mentioned above; the jets, perforated with a number of holes, are generally of metal, platinum being often used for the purpose. Two mechanical methods of spinning have been commonly used in the viscose process; one resembling that employed in the cuprammonium process, of drawing on to bobbins, in many cases of glass, washing and drying the thread thereon, winding on to smaller bobbins and twisting from these as is done with natural silk; the other and more interesting is the Topham centrifugal box already mentioned.

In this process the thread after leaving the coagulating bath passes over a roller, through a vertically reciprocating tube into a circular box rapidly rotating on a vertical spindle; centrifugal force throws the thread to the side of the box, where it builds up into an annular cake, the requisite twist being given to the thread by the revolution of the box at several thousand turns per minute. When the box is full, the cake of thread is removed and reeled into skeins, which are then appropriately finished, being first immersed in acid, if a neutral spinning bath has been used, or if an acid bath, then the skeins are washed to remove all traces of the spinning bath, freed from sulphur and other impurities, and if desired bleached and dried. The thread is then ready for the textile manufacturer, although it often at this stage has further treatment such as giving a soft finish with soluble oil or soap, or sizing with gelatin or starch, according to the purpose for which it is required.

The description of the three main processes, nitro, cuprammonium and viscose, which has been given comprises the whole industrial history of artificial silk up to the present, but a number of other methods and materials have been suggested and patented. The earliest and at one time perhaps the most promising, because it was for long successfully worked in the manufacture of electric lamp filaments, was the zinc chloride process (Eng. Pat. 16,805 of 1884, Wynne and Powell); in spite of much work it has not been satisfactorily applied in the manufacture of artificial silk. Probably the breakdown of the cellulose, necessary to obtain a solution, is too great for a thread of sufficient tenacity to be obtained on reprecipitation, and the same thing may be said of the solutions of cellulose in sulphuric acid or phosphoric acid (Ger. Pat. 72,572, Langhans).

Several cellulose compounds, ethers and esters, have been put forward as suitable materials for artificial silk. The general properties of these are similar, in that an organic solvent is necessary which would entail the use of a spinning process similar to that used for nitro silk, with all its disadvantages, and the threads when produced are impervious to water and therefore cannot be dyed without quite special methods. Among these substances are ethylcellulose (Eng. Pat. 6387 of 1913, Lilienfeld) and cellulose acetate, for which about one hundred patents have been

I. Nitro

IV. Viscose, smooth

II. Cuprammonium

V. Viscose, irregular

III. Cuprammonium

VI. Viscose, thin

granted, the earliest being Eng. Pat. 9676 of 1894. Cross and Bevan; a patent for cellulose formate has also been published (Eng. Pat. 15,700 of 1910, Vereinigte Glanzstoff Fabriken A.-G.).

The use of non-cellulose materials has been advocated for the production of artificial silk on many occasions, one of the earliest and best known being that of Millar of Glasgow, who patented the use of gelatin for the purpose (Eng. Pat. 15,522 of 1894); in this case the soluble gelatin after formation into thread was hardened with bichromate, tannic acid, alum, etc. Todtenhaupt (Eng. Pat. 25,296 of 1904) has patented the use of casein, and others have made similar claims for ossein, fibroin, and albuminoid substances.

Among the many inventors in the field there are of course those whose madness does not amount to genius, and processes have been advanced which have failed to obtain appreciation. In one case the cellulose of mulberry leaves, being the food of the silk worm, was stated to be an excellent material for the production of artificial fibres, and oil of chrysalides was put forward as an ingredient in solutions for spinning; while in order to twist the filaments together and avoid the use of the power required to rotate heavy bobbins or boxes, it has been proposed to pass the thread through a revolving tube while both ends of the thread are prevented from twisting; and a German would-be inventor having seen the drawing of an English machine, obtained a patent for it, but described it in the position in which he had seen the drawing, upside down.

Because the commercial varieties of artificial silk are all forms of cellulose, there are no outstanding differences which distinguish the product of each process from that of the others, and although an expert can often identify a specimen as nitro or viscose for example, by inspection, in many cases it is not easy to distinguish between the products of different processes, so that it is no uncommon thing for a consumer to complain to a viscose silk manufacturer that a certain batch of silk is uneven in size, or dyes irregularly, and examination to prove that the sample sent to substantiate the complaint is composed partly of viscose and partly of nitro silk.

The products with least difference are cuprammonium and viscose, for both are forms of cellulose hydrate, not to be distinguished from one another by analysis, and in many cases having the same shape of cross section, and a similar affinity for dyestuffs. The most definite method of identification in this case is that published by Maschner (Färber Zeit., 1910, XXI. 352). About 0.2 gm. of the silk is put in a test tube and 10 c.c. of concentrated sulphuric acid is poured upon it; cuprammonium silk at once turns yellow, changing in a few minutes to a yellowish red, and within half an hour the silk dissolves leaving the acid of a pale yellowish brown; viscose silk turns to a reddish brown in a minute or two, and dissolves to a brown liquid. Concentrated phosphoric acid of about 1.7 specific gravity appears to be a means of distinguishing between cuprammonium spun in an acid bath and that spun in an alkaline bath, the latter giving a brown colour, while the former, together with viscose and nitro silks, gives no coloration.

Nitrocellulose silks, whether denitrated or not, always give a deep blue colour with diphenylamine in concentrated sulphuric acid; care must of course be taken that no dyestuff or dyestuff residues, left after bleaching a dyed silk, are present at the time of testing.

Mention has been made of the cross section of fibres; this is instructive but not always distinctive. Nitrocellulose is smooth in shape but not invariably regular in form and may perhaps best be described as lobate (Fig. I.). Cuprammonium is always rounded and smooth, whether spun by the Glanzstoff process (Fig. II.)

or the Thiele or similar process (Fig. III.). Viscose, however, may be of almost any section, owing to the fact that wider chemical variations are possible in the condition of the xanthate than can obtain in the other cellulose solutions, and the complicated constitution of the spinning baths also allows of a wide range of conditions; because of this it may happen that a slight temporary variation in one of the conditions of manufacture will produce a different section in some of the thread, causing it to have a different feel or appearance when woven or knitted into a cloth, providing trouble for all concerned; also by carefully choosing the conditions and adhering very closely to them thread may be produced which is specially suitable for braiding, knitting or weaving, etc. (Figs. IV., V., and VI.). Thanks are due to Messrs. Courtaulds Limited for permission to use the photomicrographs, which were made in their laboratory, and to Mr. Stokes, who prepared the sections.

The tenacity of artificial silk, both when wet and dry, is a matter of great importance, and although some years ago artificial silk left much to be desired in this direction and is not now by any means as strong as natural silk when wet, so great an improvement has been made in recent years, that no trouble is experienced when putting it through any reasonable textile or finishing process, and it will stand wear and washing excellently, so that artificial silk is now in common use not only for braids and fancy goods, but for both knitted and woven underwear and dress fabrics.

There has been on the market during the last two or three years a considerable amount of silk which has a breaking tenacity of 1.7 grams per denier when dry and 0.75 gm. per denier when wet; what progress this means may be seen from the following table:

	Ten. dry, g. per denier.	Ten. wet, g. per denier.	Extensibility, %
Chardonnet silk ..	1.1	0.25	8.0
Lehner silk	1.4	0.36	7.5
Cuprammonium (Glanzstoff)	1.3	0.5	12.5
Viscose, 1907	1.1	0.35	15.0
Viscose, 1913	1.4	0.55	17.0
Viscose, 1917	1.75	0.75	14.0
Natural silk	2.5	2.0	21.0

With regard to dyeing, it may be said that artificial silk behaves generally like cotton, except that for most dyestuffs it has a somewhat greater affinity; it likewise absorbs moisture to a greater extent than does cotton and is commonly sold as having 11 % humidity.

This outline of the manufacture of artificial silk gives a very imperfect idea of the amount of chemical work involved, for in addition to the control of the processes, necessitating in some works several hundred quantitative chemical and physical tests daily, there are numerous problems presented by products, waste materials, effluents and water supply, which need constant attention, and there is, further, that almost illimitable field of research, cellulose, of which much has been written, and comparatively little is known; the artificial silk industry, however, has probably done as much, directly or indirectly, to increase the knowledge of the subject as has been done by the other great industries of cotton, paper, and explosives which also depend on cellulose, and without doubt in the future will further extend this branch of science.

DISCUSSION.

Mr. S. J. PENTECOST asked what method of bleaching was used. When the dyer was dealing

with artificial silk he had some troubles at times, though not so many as formerly. He found that the affinity for dyestuffs had altered greatly during the past 10 years, and it had now about the same affinity as cotton. The question of the treatment of the fibre with soluble oil or softening was one which affected the dyer, and he asked whether threads made for lace and hosiery were treated either by soluble oil or softening?

Mr. WRIGHT enquired whether distilled water was used in the process; if not, whether the author considered it would be any advantage in avoiding the introduction of lime or magnesia. If distilled water were used some of the difficulties of dyers would possibly be overcome.

Mr. F. SPROXTON alluded to the author's statement that artificial silk absorbed moisture to a greater extent than did cotton, and was sold as containing 11% of moisture. How did that 11% compare with the wood pulp from which it was made?

Dr. H. P. STEVENS said that the author had stated that it was not possible to use wood pulp for the manufacture of cuprammonium silk. Was that the only reason why he considered the cuprammonium process would be replaced by the viscose process? In connection with the former, he mentioned that the silk was wound off on cylinders, while with regard to the viscose cylinders he alluded to the Topham spinning box. Could not that be used equally well in connection with the cuprammonium process? What was the object of allowing the solution to mature for months before use?

Dr. R. H. PICKARD asked the precise meaning of the sentence regarding 11% humidity. Did it mean it contained 11% of moisture as sold? He thought cotton would contain more than 5%—probably nearly 8%.

Mr. WILSON replied that sodium hypochlorite solution was used for bleaching. Much of the dyers' trouble was due to purchasing unbleached thread, and then bleaching with the Lancashire cotton bleach: that caused irregular dyeing. The aim had been to make the affinity of artificial silk for substantive dyestuffs the same as that of cotton, and that had been approximately attained. The treatment with softening materials was not general. The greater part of the thread as sent out to textile manufacturers was untreated; it was sized or softened according to the requirements of the manufacturer. The question of using distilled water had to be set aside owing to the huge quantities of water required. If trouble were found with soap or soluble oil in a thread it was probably due to its having been bleached with calcium hypochlorite rather than sodium hypochlorite. Washing with hard water was another reason for trouble in the spinning bath; softer water should be used. The 11% humidity referred to the silk as it was sent out: it lost 11% of moisture on drying for about 6 hours at 100° C., and that figure was taken as a standard. It would absorb more, and it could be produced with considerably less. Wood pulp contained about 8 or 9% as a rule, but varied very much: it was sold on a basis of 10%. Manufacturers did not use wood pulp for the cuprammonium process because they found cotton easier to work with. Wood pulp, unless well produced, did not give a good thread in cuprammonium solution. The same answer applied to the Topham box. He did not see, however, why it should not be made to work; at one factory in Germany two processes were used: the Topham box for one part of the viscose, and glass cylinders for the cuprammonium. As to the question of keeping the solution for some weeks before use, he thought there were particles which took a long time to come properly into approximate solution; certainly the cuprammonium solution was improved if kept for about

that period. If only kept a few days the results were quite inferior.

The PRESIDENT called attention to the fact that Messrs. Cross and Bevan had placed the sum of £20 at the disposal of the Society as a prize for an essay on "The Interconnection of Economic Botany and Chemical Industry"; and their friend, Mr. Latham, of Weybridge, had presented £300 as a grant towards research undertaken by such one of the competing essayists as might be judged to be of conspicuous ability. He mentioned that in connection with this paper since the industry concerned was one which had arisen out of the successful discoveries made by Messrs. Cross and Bevan.

A RESUME OF THE PRESENT POSITION OF THE ACTIVATED SLUDGE PROCESS OF SEWAGE PURIFICATION.

BY EDWARD ARDERN, M.Sc.

Since the inception in December, 1912, of the Manchester experiments which led to the activated sludge process, the results of which were first communicated to this Society in April, 1914, a number of investigators have undertaken experimental work on the subject, accounts of which are to be found in numerous contributions to the scientific and technical literature of this country Canada and the United States.

The results of the early investigations were such as to encourage trials of the process on a working scale and during the past 2 or 3 years considerable developments in large scale practice have taken place in America and also in this country despite the retarding influence of war conditions.

It has been thought desirable therefore to collect and summarise the data which has accumulated as the result of experience gained in the operation of working scale installations, with the view of ascertaining how far the process has been demonstrated a practical proposition, and in which direction further information is required.

The number of large scale units actually in operation or in course of construction renders it impossible to make reference to each individual plant. It is therefore proposed in the present paper to deal more particularly with typical installations with which the writer is personally acquainted or in regard to which authentic information is available.

MANCHESTER.

Dayphulme (Main Works).—A rectangular tank 25 feet by 16 feet by 8 feet deep (water level), has been in operation at these works on the fill and draw system for the past three years.

Certain alterations in the arrangement of the tank have been made from time to time as the result of experience gained with its operation.

Some nine months ago the tank was entirely remodelled in the light of the most recent knowledge in regard to tank design and method of air admission.

The floor of the tank is now constructed on the ridge and furrow system with rows of diffusers placed along the furrows, such that the net diffuser area is about one-sixth the total tank area.

The diffusers, which were supplied by Messrs. Jones and Attwood, Ltd., consist of shallow ear iron trays, 1 foot square (over all), with an insulating cover of porous material having a central orifice for the admission of air to the under side of the tray.

There is an overhead system of air supply pipe with down pipes, each fitted with tee pieces so that they may serve two or three diffusers.

The purified effluent, after settlement of the sludge, is discharged from the tank through a sectional stand-pipe.

A novel feature of the installation is a mechanical arrangement (devised and patented by Messrs.

Jones and Attwood, Ltd.) whereby a pulsating air supply is automatically obtained.

Attached to each air pipe serving a row of diffusers is an ordinary mushroom type valve which is operated by a pressure diaphragm receiving its air pressure intermittently from one of a series of pilot valves. The pilot valves are operated from a cam shaft which is turned by an air wheel immersed in oil.

The design of the cams at present employed gives a ratio of the time of admission of air to the diffuser to the period of rest of 1:2; the actual time of these periods can be varied by regulating the speed of the cam shaft. As a general rule each set of diffusers receives air for 5 seconds at intervals of 10 seconds.

The above ratio may of course be varied by substituting cams of a different design to those in use.

With the exception of disturbance due to excessive quantities of oily matter or to the presence in the sewage of strongly inhibitory trade effluents, no difficulty has been experienced in obtaining an entirely satisfactory purification of Manchester sewage with an average aeration period of from 4 to 6 hours, as will be seen from the following analytical returns.

Results in parts per 100,000.

	Screened sewage.	Effluent.	Purification.
4 hours' oxygen absorption...	10.40	1.60	85
Free and saline ammonia ..	2.86	2.06	—
Albuminoid ammonia	1.00	0.17	83
Nitrite and nitrate	—	0.30	—
Dissolved oxygen absorption after 5 days' incubation at 65° F.	—	1.20	—
(Royal Commission test)			

The above aeration period allows the tank to receive 3 fillings per day and as the water level is lowered 6 feet at each discharge the daily volume of sewage dealt with is 45,000 gallons.

For some time past, however, the problem has been complicated by the presence in the sewage of an undue proportion of difficult trade effluents, consequent on the very great activity in the chemical industry in the Manchester district, with special reference to the production of explosives.

In the absence of other units or a reactivation sludge tank, which would provide active sludge for inoculation in case of disturbances thus caused, it has been necessary to allow periodically an increased aeration period in order to maintain an entirely satisfactory effluent which readily passes the standard suggested by the Royal Commission on Sewage Disposal viz., not more than 2.0 parts of dissolved oxygen per 100,000 absorbed after incubation for 5 days at 65° F.

The most important development in connection with this tank has been the success of the pulsating gear by means of which it has been possible to reduce the air consumption by practically 50%, i.e., from 15 cubic feet free air per sq. foot tank area per hour to about 8 cubic feet. The working pressure is from 4½ to 5½ lb. Calculated on a 6-hour aeration period and allowing three fillings per day the air consumption is equal to 1.28 cubic feet free air per gallon sewage treated. Assuming a well-designed air compressor suitable for the purpose and power equivalent to 0.5 pence per electrical unit, it has been estimated that the compressed air would cost about 12s. 6d. per million cubic feet. On this basis the air cost is equal to 16s. 6d. per million gallons treated.

The experience gained with this tank has also demonstrated:—

1. The necessity for effective removal of

excessive quantities of oily matter (trade discharges) from the sewage, which is liable to have an emulsifying effect and thus prevent satisfactory clarification.

2. The importance of adequate removal of heavy suspended matter such as grit, sand, etc., or otherwise difficulty may be experienced in the accumulation of the sludge, with the likelihood of the formation of deposits of de-aerated sludge which undergo secondary decomposition and thus produce conditions which are inimical to the complete success of the process.

3. The advantage of a filtered air supply in obviating trouble with diffusers.

4. In the case of certain industrial sewages the necessity for the provision of a re-aeration tank for economy in the maintenance of the process.

MANCHESTER.

Withington Works. The experimental investigation of the application of the activated sludge process to the purification of the weak domestic sewage (50 gallons per head) dealt with at these works gave results * which were so far in advance of those obtained with the trade sewage, at Davyhulme, that it was decided to lay down a large-scale unit with the view of studying the process under working conditions.

Such a plant, which is designed to be operated on the continuous-flow system, is now in course of construction and it is hoped will be ready for use before the end of the present summer.

The aeration chamber, which is 100 feet long, is divided longitudinally into 5 channels each 4 feet wide. The depth of the tank measured from the diffusers to the water level is 5½ feet. Its total capacity is 55,000 gallons.

The floor of the tank is constructed in concrete on the ridge and furrow system, the ridges having a slope of 35 degrees to the horizontal.

Aeration is effected through rows of diffusers placed in the furrows, which are at 6ft. 9 in. centres. The diffusers are of course arranged transversely to the flow of sewage.

The sewage and sludge on flowing through the whole length of channels, i.e., 500 feet will thus pass over 75 different diffuser areas, which should secure effective mixing of the sewage and sludge and obviate to a large extent the possibility of short circuiting.

An overhead system of air pipes is provided and the air will be admitted to the diffusers through a series of down pipes which are arranged so that one pipe serves two diffusers. Valves are attached to the various distributing pipes so that the air supply may be regulated and equally distributed.

The diffusers are each 1 foot square over all, so that their total area is approximately one-seventh of the aeration tank area. The ratio of the net diffusion area to total tank area is practically 1:10.

The removal of the sludge from the purified effluent will be effected in a deep pyramidal settlement tank the dimensions of which are 23 ft. 6 ins. x 26 ft. 6 ins. in plan, with a depth from water level to apex of tank of 23 ft. 6 ins.

The sides of the tanks are constructed with a slope of 60 degrees to the horizontal.

The inlet and outlet arrangements of this tank have been designed on the basis of the results obtained by Mr. W. Clifford, Manager and Chemist of the Wolverhampton sewage works, from a careful study of the principles involved in the correct design of settlement tanks of this type.

The mixture of purified effluent and sludge is admitted to the centre of the tank through a 15-inch pipe which discharges within a guard chamber 6 feet square and 10 feet deep, in a manner

* Arden, this J., No. 2, Vol. 36, 1917.

designed to dissipate, as far as possible, the energy of the incoming liquid. The final effluent leaves the tank over a peripheral outlet cill.

The total capacity of the tank is 27,000 gallons or practically one half that of the aeration chamber.

The sludge is discharged by hydraulic head from the apex of the tank through a 6-inch return pipe to a separate chamber fitted with diffusers. The sludge is lifted from this chamber to the aeration tank by air lift, or surplus charge may be discharged on to drainage beds.

The installation is designed to deal with 250,000 gallons of sewage per day, which after accounting for the volume of sludge employed will allow an aeration period of 1 hour and a stay of 2 hours in the settlement tank.

This plant is being constructed under the advice and direction of the writer.

Messrs. Jones and Attwood, Ltd., are responsible for the whole of the equipment (apart from air compressor) and in consultation with the writer also for the general design of the plant.

The structural work involved is being carried out by the Corporation Main Drainage staff under the direction of Mr. Bertram Meek, the Acting City Engineer.

The air supply will be obtained from a belt-driven Reavell air compressor designed to deliver 500 cub. feet free air per minute at anything up to 15 lb. pressure. It is anticipated that the normal working pressure will be about 4 lb.

In view of the excellent results obtained at Dayhulme, in all probability a pulsating gear will be provided at an early date.

SALFORD.

The first really large scale plant in this country was brought into operation at the Salford sewage works in June, 1914, where tanks already equipped for aeration purposes were readily adapted to meet the requirements of the activated sludge process.

A full description of this plant together with the results obtained may be found in papers by S. E. Melling,* F.I.C., and W. H. Duckworth,† the Works Manager.

The plant was laid down under the advice of Mr. Melling, the Consulting Chemist to the Corporation, who is responsible for its control.

The original tank was operated on the fill and draw method but subsequently a continuous-flow system was also brought into use. Both these plants have now been in operation side by side for some time past.

In each case, aeration is effected through a system of perforated pipes laid on the floor of the tanks, which are rectangular in shape.

In the continuous-flow system the settlement of the sludge is effected in a series of 4 square tanks, with sloping sides. The settled sludge is periodically pumped back to the inlet end of the aeration chamber.

The total capacity of the aeration chamber is 12,000 gallons and of the settlement tanks 6000 gallons.

For experimental purposes both plants have been operated under various conditions and rates of flow.

Despite certain disadvantages the plant is under excellent effluents are invariably obtained, with a continuous rate of flow of 51,000 gallons per day, which allows an aeration period of approximately 4 hours and a stay of about 2 hours in the sedimentation tanks.

With the fill and draw tank entirely satisfactory effluents are obtained with an aeration period of

not more than 3 hours, which allows a daily volume of 132,000 gallons to be dealt with.

The Salford investigations have been very valuable in demonstrating on a working scale the principle of the process, and in thus confirming at an early date the original Manchester experimental work.

The results obtained have been an undoubted incentive to other authorities.

Admittedly, however, they have not assisted in determining the practicability of the process, as the volume of air employed is prohibitive from the point of view of cost.

The reconstruction of this plant on the most up-to-date lines is therefore awaited with interest, as in the writer's opinion there is every reason to believe that under suitable conditions equally good results will be obtained with a reasonable air consumption.

WORCESTER.

This plant was designed and installed by Messrs. Jones and Attwood, Ltd., under special agreement with the Worcester Corporation, whereby the payment for the installation was conditional on the successful operation of the process so as to comply with certain requirements in regard to the character of the effluent obtained, and the volume of sewage treated.

The installation, which is designed to deal with 750,000 gallons (day weather flow) per day, was brought in operation in April, 1906.

The writer is indebted to the firm* and to Mr. T. Caink,† the City Engineer of Worcester, for the following information relative to this installation which is the largest in operation in this country.

The tank placed at the disposal of the firm was 80 feet long by 72 feet wide and 18 feet deep. It was divided longitudinally into 9 bays 8 feet wide, which were subdivided by 3 transverse walls, thus forming 36 compartments.

In the adoption of this tank for the trial of the process, five bays are used as the aeration chamber and the other 4 bays for settlement purposes.

The five aeration bays are arranged as follows:—The first bay though 8 feet broad at the top is only 5 feet at the bottom due to the batter of the outside wall. The bottom of the first bay is arranged with ridge and furrows at 5 feet centres, the furrows each containing 5 air diffusers each 12-inch square over all, which are of course placed transversely to the flow of sewage. The lower part of each transverse wall is cut away, making an opening 3 feet deep right across the tank above the top of the ridge. The ratio of total diffuser area to tank area in this bay is 1:5 or 1 to 7 if the actual diffusion area is considered.

The other four aeration bays are arranged in pairs, each pair making a circulating tank. The bottoms of these bays are formed with ridges and furrows, saw-tooth form, at 10 feet pitch, with 80 diffusers in each furrow, so that the ratio of diffuser area to tank area is 1:10 or 1:14 for actual diffusion area.

Advantage is taken of the transverse walls which are used as baffles and these together with intermediate wooden baffles give a baffle alongside each line of diffusers which checks the back flow and allows the rising current of sewage to flow forwards, thus giving a much more rapid horizontal circulation than would be obtained by the natural flow of sewage.

The mixture of purified effluent and sludge leaving the aeration chamber enters the settlement tanks underneath a timber baffle 8 feet below the surface. The settled sludge is removed from a

* Activated sludge System. Booklet, No. 52, Messrs. Jones and Attwood, Ltd.

† Activated Sludge Process of Sewage Purification—Experiments at Worcester, by T. Caink, City Engineer. Meeting of Association of Managers of S.D. Works, July 7th, 1917.

series of collecting sumps through a system of pipes to the inlet sewage chamber.

The settlement tanks have been partially reconstructed since the plant was brought into operation, as will be seen later.

A similar system of air distribution pipes is employed to that described in the Withington plant.

The air compressor is of the Ingersoll-Rand horizontal type and is belt driven by electric motor (d.e.) capable of developing 40 B.H.P. When running at 235 r.p.m. it has a piston displacement of 615 cubic feet per minute and an actual delivery of 562 cubic feet.

The total capacity of the aeration chamber is given at 317,000 gallons, which after allowing 20% for the volume of activated sludge present gives an average aeration period of about 8 hours when working at the rate of 750,000 gallons per day.

In actual practice it is found the volume of this sludge returned to the aeration chamber is considerably in excess of 20% of the volume of sewage treated.

The total capacity of settlement tanks is sufficient to allow a 2 hours' detention when working at the above rate. As a matter of fact, however, for the greater part of the period the plant has been in operation, the whole of the settlement bays have not been in use.

The Worcester sewage cannot be termed a strong sewage as the flow is equal to approximately 40 gallons per head, and although the City Engineer states that a variety of trade effluents are discharged into the sewers, there appears none of an inhibitory character present in the sewage.

Apart from stoppages due to structural alterations to the settlement tanks, the plant has been in continuous operation for the past 14 months.

During this period the rate of flow has varied from 600,000 gallons to rather over a million gallons per day. The average daily flow dealt with may be taken at about 750,000 gallons.

In the following table are given the average results of analyses made by the Worcester City Analyst of the screened sewage (9 samples) and final effluent (12 samples) from June, 1916, to May, 1917.

Results in parts per 100,000.

	Screened sewage.	Final effluent.	Purification.
4 hours' oxygen absorption	3.70	0.56	85
Albuminoid ammonia	0.76	0.14	82
Suspended solids	14.3	0.72	—

The following are the analytical returns for snap samples taken by the writer on the occasion of a visit to the Worcester sewage works on July 13th, 1916, when a rate of flow of 825,000 gallons per day was recorded.

Results in parts per 100,000.

	Screened sewage.	Final effluent.	Purification.
4 hours' oxygen absorption	3.90	0.46	88
Free and saline ammonia	2.00	1.86	—
Albuminoid ammonia	0.89	0.06	93
Nitrite and nitrate (as NH_3)	—	0.33	—
Dissolved oxygen absorption after 5 days' incubation at 65° F.	—	0.76	—
(Royal Commission test.)			

The final effluent was perfectly clear and colourless and contained very little suspended matter.

These results indicate that a high degree of

purification is obtained with the production of an entirely satisfactory effluent.

It has been found unnecessary to run the compressor at full speed in order to keep the sludge in suspension in the aeration chamber. Under normal conditions the compressor speed is 160 r.p.m. which gives a free air delivery of 384 cubic feet per minute and about 20 B.H.P. The working air pressure is 9 lb.

This volume of air employed is equal to only 7 cubic feet per square ft. tank area per hour and is inclusive of the air used by air lifts for returning the sludge to the aeration chamber.

Working at the rate of 750,000 gallons per day the air consumption is equal to 0.7 cubic feet free air (actual delivery) per gallon of sewage treated.

The electric motor driving the compressor absorbs 16 units per hour which at $\frac{1}{3}$ d. per unit, the cost at Worcester, is equal to 32s. per million gallons sewage treated when working at the above rate.

Recently, sand drainage beds have been constructed to receive the surplus sludge but the results of their operation are not yet available, nor is it possible to say with any certainty the volume of sludge produced per million gallons dealt with.

It is stated that practically throughout its operation no trouble has been experienced with the working of the aeration chamber. So far as can be ascertained the sludge is kept in full suspension and there is no evidence of any serious sludge deposits.

Up to the present, the settlement tanks appear to be the limiting factor in regard to the volume of sewage which the installation is capable of dealing with.

From the commencement this portion of the plant gave unsatisfactory results, with strong evidence of the retention of sludge and subsequent return to the aeration chamber of sludge in a more or less septic condition, with consequent disturbance of the purification process.

At intervals the floors of the 1st and 2nd settlement bays have been reconstructed so that they now have a slope of 60 degrees to the horizontal.

This alteration appears to have overcome the difficulty of sludge retention, but owing to the insufficient capacity of the two converted settlement bays in operation, appreciable amounts of suspended solids pass away in the effluent if the rate of flow is increased seriously over 1,000,000 gallons per day.

There seems every reason to believe that with improved settlement conditions this plant would be able to treat satisfactorily a considerably larger volume than is at present being dealt with, with corresponding decrease in air costs.

The outstanding feature of this installation is the low air consumption which is obtained without the assistance of a pulsating air supply. It may be noted that it is not more than one half the volume employed in the American installations, and is very considerably less than the estimate based on the early investigations.

STAMFORD (LINCOLNSHIRE).

The sewage of the borough of Stamford is exceptionally strong, as the flow does not exceed 20 gallons per head of population and it contains an undue proportion of abattoir refuse.

It is therefore of interest that Messrs. Jones and Attwood Ltd., have designed and installed an activated sludge plant at the Stamford sewage works under an agreement with the Corporation on similar lines to the Worcester agreement.

Tanks previously employed as closed septic tanks have been adapted for the purpose of this plant.

The installation is designed to deal with the screened sewage at the rate of 100,000 gallons per day on the continuous flow system.

The aeration chamber is 80 feet long by 14 feet wide & 6 feet deep from water level to diffusers; its total capacity is 43,700 gallons.

It is divided longitudinally so as to form a channel 7 feet wide and 150 feet long, the last 10 feet of the return arm of the channel being occupied by a small Dortmund settling basin whose capacity is 3500 gallons. A further settlement tank is provided which brings the total capacity of the settling tanks to 8000 gallons.

The floor of the aeration channels is formed in ridge and furrows with rows of 7 diffusers (each 1 sq. foot over all) occupying the furrows which are placed transversely to the flow of sewage. The ratio of the diffuser area (gross) to tank area is approximately 1 to 6 or of net diffusion area to tank area of 1 to 9.

The compressed air supply is obtained from a suitably designed compressor worked by an oil engine which cannot be regarded as efficient, the total power absorbed being 1 B.H.P.

The volume of air supplied for diffusion and air lifts for return of sludge from settlement tanks is 125 cubic feet per minute (working pressure about 4 lb.) which amounts to just over 7 cubic feet per sq. ft. tank area per hour and on the basis of 100,000 gallons treated per 24 hours is equal to 1.8 cubic feet free air per gallon of sewage.

By the courtesy of Messrs. Jones and Attwood, Ltd., the writer is enabled to give the following average results of analyses of screened sewage and effluent made by Mr. E. Gaul, M.Sc. (Manchester University), between April and November, 1916.

Results in parts per 100,000.

	Screened sewage.	Final effluent.	Purification.
4 hours oxygen absorption...	10.91	1.67	% 90
Free and saline ammonia ..	4.27	3.40	—
Albuminoid ammonia	1.49	0.195	86
Nitrite and nitrate	—	0.28	—

On account of the inefficiency of the oil engine the actual power costs are high although the air consumption is low. This cost is given at 3d. per hour, which is equal to 6s. per 100,000 gallons or 60s. per million gallons sewage treated. In this consideration the strength of the sewage must be borne in mind, the aeration period allowed amounting to nearly 9 hours.

As in the case of the Worcester plant some difficulty has arisen in regard to the satisfactory operation of the settlement tanks. It is understood, however, that a reconstruction of the floors of these tanks and alteration of inlet and outlet arrangements have effected considerable improvement in their efficiency.

Mr. Ryman, the Borough Engineer of Stamford, reports recently that labour difficulties during the past few months have prevented this plant from being operated throughout the twenty-four hours. At the present time it is only at work for ten hours out of the twenty-four, during which period it is operated at the normal rate of 100,000 gallons per 24 hours.

Despite the fact that working under these conditions the sludge is not aerated for a period of 14 hours day by day, which must be distinctly disadvantageous to the maintenance of an active sludge, the Borough Engineer states that satisfactory effluents are still obtained.

AMERICAN INSTALLATIONS. MILWAUKEE, WIS.

The following description of this plant which was the first large scale American installation is taken from an article in "Engineering News."

*"Engineering News," New York, October 12th, 1916, Vol. 76, No. 15.

The installation, which was built by the Milwaukee Sewage Commission, of which George H. Benzenberg is chairman, L. Chalkley Hatton, chief engineer, and William R. Copeland, chemist and bacteriologist, was designed to deal with 1,600,000 gallons (U.S.A.) on the continuous-flow system and was put into operation in January, 1916.

It consists of eleven circular tanks each 30 feet in diameter. Eight of these are used in series for aeration purposes, one for settlement of sludge, and two for the re-aeration of the sludge prior to its return to the aeration tanks.

Two curved divisional walls are built in each aeration tank so as to form a channel of a total length of 912 feet, through which the mixture of sewage and sludge flows in its passage through the eight tanks. The floor is furrowed and lines of diffusers are fitted along the furrows longitudinally with the flow of sewage.

Air diffusion is effected by 12-inch square "filtros" plates which are set in cast-iron frames and which afford an air-supply beneath the centre line of each plate.

The ratio of diffusing surface to tank surface is 1 : 8.5.

The depth of these tanks from water level to diffuser is 10 feet, the average depth being 9 feet.

The holding capacity of each is 45,000 gallons or 360,000 gallons (U.S.A.) for the group.

The capacity of the sludge re-aeration tanks is similar, so that their total capacity is 90,000 gallons (U.S.A.)

The sedimentation tank is constructed with sloping sides at an angle of 45 degrees, terminated in a 48-inch cast-iron pipe which extends 23 feet 3 inches below the bottom of the tank. Its holding capacity is 33,000 gallons (U.S.A.), excluding 2260 gallons (U.S.A.) held by the 48-inch pipe.

The sludge is raised by air-lift to the sludge aeration tanks from which it is returned by a gravity pipe to the sewage inlet channel.

Compressed air is supplied by a Connersville position blower of the Boston type, with a capacity of 2406 cubic feet of free air per minute compressed to 5 lb. per sq. inch.

The total cost of sewage treatment by this plant is stated to be between six and seven dollars per million gallons (U.S.A.) exclusive of sludge charges.

The cost of sludge disposal, dewatering or drying is given at \$3.17 per million gallons, making a total charge of from \$9 to \$10. A gross return from the sale of dried sludge is expected of about \$6 per million gallons treated, which brings the cost of treatment and sludge disposal to between \$3 and \$4 per million gallons, including all overhead charges.

The following quotation from a letter from Mr. T. Chalkley Hatton to Mr. Hammond published in the paper previously referred to, summarises the experience with this plant up to the autumn of 1916.

"The plant was designed to treat 1,620,000 gallons of raw, coarse screened sewage with a four-hour aerating period, and 25 per cent. of activated sludge retained in the aerating tanks, and produce an effluent showing a removal of at least 95 per cent. of suspended matter and bacteria, with a dissolved oxygen content of five parts per million.

"Owing to the design of the sedimentation basin we have not been able to treat more than 1,400,000 gallons through the plant, and in fact 1,200,000 gallons is the limit from which we can get a satisfactory effluent. We provide for a 27-minute sedimentation with 1,620,000 gallons flowing through. Our observations to date lead us to the belief that one hour's sedimentation period would be nearer correct.

"We believe that our aerating capacity is sufficient to treat the full amount designed for,

but owing to the small porosity of the plates which runs from 1.85 to 4.50 cubic feet of air per minute per square foot of surface under 2 inches water pressure; and the failure of the air filter to intercept all of the dust and oils, the diffusion of air throughout the aerating tanks is not as uniform as we should like it, this results in the deposition of sludge upon some of the plates and the uneconomical use of the air, and the building up of pressure.

"From our experience here we believe we can practically overcome these difficulties in the design of the air filter; in changing the design of the bottom of our tanks; placing our air diffusers closer together and increasing their porosity; and particularly by intercepting the mineral matter, which now reaches the plant in great quantities, by well-designed grit chambers.

"The effect of cold weather upon the operation of the process is to increase the amount of air necessary and to decrease the nitrate in the effluent, but during February, March, and April we secured an average of 98% removal of suspended matter, 95% removal of bacteria, 3 to 5 parts of dissolved oxygen, no nitrates, a stability of 108 hours without dilution, and a very clear effluent in spite of the fact that the temperature of the raw sewage varied from 34° F. to 49° F., and the outside temperature from 14° F. below zero to 46° F. above."

The writer is indebted for the following information relative to other typical American plants to a paper presented by Mr. George T. Hammond, Brooklyn, N.Y., to the Congress of the American Society of Municipal Improvements, in November, 1916, which gives a complete account of the numerous activated sludge plants in operation in the States and Canada.

HOUSTON (TEXAS).

An interesting experimental plant designed by the city engineer Mr. E. E. Sands, was in operation at Houston, Texas, from September 1915, to June, 1916.

It consists of a continuous-flow plant with aeration tank approx. 28 feet by 11 feet by 7 feet 9 inches (greatest depth), the capacity of which is 10,400 gallons (U.S.A.), and a settlement tank 14 feet by 11 feet by 7 feet 5 inches deep with a capacity of 3300 gallons.

The aeration chamber is hopper-shaped, 11 feet 2 inches wide at the top and 14 inches at the bottom. The aeration is effected through diffusers ("filtros" plates), 12 inches square, placed in furrows at 3 feet 6 inches centres along the central axis of the tank.

The sludge is settled in a pyramidal settlement tank, from which the sludge is returned by hydraulic head through a 3-inch pipe to the inlet of the aeration chamber.

According to Hammond, for some months this plant treated 86,000 gallons of sewage per day with the production of an effluent the relative stability of which was 95% and the oxygen consumed varied from 1.0 to 1.6 parts per 100,000.

At this rate, an aeration period of 2.3 hours would be given after allowing for 20% sludge in the tank.

The air consumption was 6800 cubic feet per hour, which is equal to 1.6 cubic feet per gallon (U.S.A.) of sewage treated.

As the results of experience gained with this plant, certain improvements in design have been embodied in the large scale plant which it is understood is now in course of construction.

These improvements are concerned mainly with the design of the settlement tank, the sides of which it is considered should have a slope of 60 degrees to the horizontal and the arrangement of the diffusers transversely to the flow of sewage instead of parallel as in the above plant.

CHICAGO, ILL. (MESSRS. ARMOUR & CO.).

As the result of a fairly extensive trial of the application of the activated sludge process to the purification of stock-yard sewage, it has been found that despite the abnormally strong character of this sewage, satisfactory purification can be maintained with an eight-hour aeration period, working on a continuous flow system.

Owing to the poor distribution of air effected by the diffusers employed, due to their uneven porosity, they have been replaced in this installation by iron pipes perforated with $\frac{3}{8}$ inch holes, 2 inches apart and staggered, with improvement in the air distribution.

The air consumption is stated to be about 3 cubic feet per gallon of sewage treated and the cost is given at 37s. 6d. per million gallons treated.

The problem of dewatering and drying the resultant sludge has been investigated. The results are not yet available but it is suggested that decantation followed by treatment in a Worthington press as used at Milwaukee appears to give the best results.

ILLINOIS STATE WATER SURVEY.

(Champaign, Ill.)

This plant which has been laid down under the direction of Prof. Edward Bartow, who was responsible for some of the earliest studies of the activated sludge process, was designed to treat 200,000 gallons of domestic sewage per day.

The aeration chamber is a rectangular concrete tank 17 by 36½ feet in plan and 9½ feet deep, with a capacity of 36,000 gallons.

Three longitudinal walls divide the tank into 4 compartments. The bottom of each compartment is built with hopper sides.

Aeration is effected through "filtros" plates embedded in concrete on the floor of the compartments. The channel below the "filtros" plates is divided into sections so that each set of 6 plates is separated from all the others. A one-inch air pipe leads to each set of plates from a 3-inch continuous air main.

The settlement tank is built of wood and has a hopper bottom. It is 6 feet by 10½ feet in plan and 10½ feet deep at the lowest point, and has a capacity of 3700 gallons.

The sludge is withdrawn from this chamber by air lift and can be discharged either into the sewage feeding the aeration chamber or on to drainage beds.

It is stated that satisfactory effluents are obtained with a stability of from 5 to 16 days. The effluent is clear, odourless, and sparkling, but at times contains small quantities of sludge.

Owing to insufficient capacity of the settling chamber it has been necessary to run the plant at considerably less than one half the designed capacity. Additional settling chambers are being installed which it is anticipated will enable the plant to be operated at the normal rate.

Other investigations in regard to the practical application of the process have been carried out at Brooklyn; Baltimore, where tanks previously in use as Imhoff tanks are being employed, Cleveland, San Marcos, and Edmonton, and experimental work has been continued at the Lawrence Experiment Station of the Massachusetts State Board of Health.

Taken as a whole, the results obtained from the operation of the various American installations are most encouraging.

Apart from certain failures in regard to air distribution, the difficulties met with may be ascribed to a very large extent to the fact that at the time these plants were installed only meagre information was available in regard to the most suitable design of plant to adopt.

The Milwaukee plant has suffered from the start from the consideration given to the possibility

of conversion to an entirely different method of sewage treatment in case the activated sludge process did not prove successful, while the trial of the process at Baltimore has been handicapped by endeavouring to adapt an existing plant which appears most unsuitable for the purpose.

The experience gained with the American installations has been valuable in indicating where improvements may be effected in their design, with especial reference to the obviation of short circuiting of the sewage in the aeration chamber and the settlement and return in a fresh condition of the activated sludge to the aeration tanks.

Plants embodying improvements in these directions should be more likely to meet the actual requirements of the process, and thus give a better purification at a lower cost.

SUMMARY.

An endeavour is made in the following paragraphs to summarise the present position of affairs and to indicate where further information is required.

Briefly stated, the problem of the successful application of the activated sludge process to the large scale treatment of sewage is to determine the most economical and efficient method by which the activated sludge may be kept in intimate contact with the sewage under strictly aerobic conditions.

The process may be carried out in a till and draw tank or in a continuous flow system.

The original experimental work was undertaken on the lines of the former method, and there can be no doubt that for a given air consumption it gives a more effective purification than the latter method, for the reason that there is no possibility of short circuiting of the sewage and there is practically no difficulty in obviating deaeration or putrefaction of the sludge.

In comparison with the continuous-flow system it suffers however from the following main disadvantages (i). Absorption of fall, required for the discharge of the tanks; (ii.) increased operation attention; and (iii.) increased possibility of diffuser difficulties by the constant periodical settlement of the sludge on the floor of the tank.

For these reasons the general tendency for large scale operation is towards a continuous-flow system in which it is of course necessary to provide a separate settlement tank and to make provision for the return of the sludge to the aeration chamber.

With regard to the design of the aeration chamber, the experience gained so far indicates fairly clearly this should be rectangular in plan and that the main tank should be sub-divided so that a long length of travel is assured with the idea of reducing the likelihood of short circuiting.

It is generally conceded that within limits the deeper the tank the greater the economy in power required for aeration purposes, but of course the questions of site conditions and cost of construction are involved in this consideration.

In the majority of cases porous diffusers have been employed as a means of aeration, but some difference of opinion exists as to the practicability of their general adoption.

In this respect certain American experience is distinctly adverse. In one instance, at any rate, they have been replaced by perforated pipes, and Hammond is of opinion that a perforated pipe grid offers advantages over porous tile diffusers.

On the other hand, diffusers have operated satisfactorily in various other plants, and at Milwaukee, although certain difficulties have been experienced with the diffusers employed, it is believed that these difficulties may be overcome by a more suitable type of diffuser and air filter. In fact, Chalkley Hatton, judging from experimental investigations, states that the amount of air used by the method of perforated pipes is too great to make the process attractive to them at Milwaukee.

Recent English experience with the latest type of porous tile is more favourable to the use of diffusers. As previously stated, very little if any diffuser trouble has arisen at the Worcester plant, which experience is corroborated by the use of similar diffusers at Davyhulme and Withington.

It is, however, advisable that they should be so fitted that they can be removed without difficulty for periodical inspection and cleansing, if required.

In the writer's view, it is also important to provide stop valves by means of which the air supply to each set of diffusers may be regulated, in order to ensure as far as possible an equitable air distribution, as it is obvious that uniform distribution is essential for economy in air consumption.

Care should be taken in the design of the aeration chamber to obviate the formation of sludge deposits, which are liable to undergo secondary decomposition and thus produce conditions inimical to the complete success of the process.

Up to the present, this point has been met generally, by constructing the floor of the tank on a ridge and furrow system, the diffusers being placed in the furrows.

Experience has shown that the diffused air should be admitted transversely to the flow of sewage rather than parallel to the central axis of the tank, as being more likely to obviate short circuiting.

There are obvious objections to this type of tank, such as cost of construction, and reduction in capacity by reason of the space occupied by the ridges. Attention is therefore being directed towards obtaining a suitably designed flat-bottomed tank.

The question of the ratio of diffusion area to tank area is important. This ratio has varied widely from 1:3 to 1:10 or even more. Further information and experience is required before any definite conclusions can be arrived at, and of course the question is largely influenced by the general design of the tank.

While discussing the question of diffusers, reference should be made to the possibilities of a pulsating air supply, as it affects their use to an appreciable extent.

Obviously the less volume of air applied to the diffusers the greater the liability to trouble; on the other hand economical operation requires the air consumption reduced to the minimum.

It follows, therefore, that if a pulsating air supply be employed, the total air consumption may be considerably reduced without diminishing the volume of air passed through the diffusers when they are in actual operation. If, therefore, the intermittency can be so arranged as to avoid settlement of sludge on the diffusers, a definite advantage is secured.

Experience at Davyhulme with the pulsating gear, to which reference has been made, indicates that this method of operation is full of possibilities in the direction of securing economy in air consumption.

It is, of course, well known that only a small proportion of the air employed when using diffusers, is required for the maintenance of the bio-chemical changes involved in the purification process, and for this reason attention should be drawn to an interesting series of experiments described by Mr. J. Howarth,* Manager of the Sheffield Sewage Works.

These experiments were undertaken largely as the result of difficulties met with in the use of porous tile diffusers, and are concerned with the aeration of sewage in contact with activated sludge, by air currents induced by mechanical means. The effect of a combination of aeration with a very low air consumption, and mechanical agitation, is also studied.

*Proceedings of the Association of Managers of S.D. Works, 1916.

This question is almost entirely one of cost in which purely engineering considerations are involved. The writer therefore awaits with interest the outcome of the extension of this investigation which he is informed by Mr. Howarth is under consideration.

The next point to consider is the design of the settlement tank and return of the sludge to the aeration chamber.

It is in this respect that practically the whole of the plants already in operation have failed in some degree to meet the requirements of the process.

This failure in design has had usually a two-fold effect. The first, a limiting one on the flow which can be treated satisfactorily, by reason of the inadequate settlement afforded, if the flow exceeds a certain rate, and the second, the inability to avoid sludge retention which results in the return to the aeration chamber of sludge in a more or less putrefactive condition, obviously to the disadvantage of the process.

The first difficulty may be easily overcome by increasing the capacity of the settlement tanks. Further research is, however, required to determine the best form of the inlet and outlet arrangements of the upward flow settlement tank, which appears to be the most suitable type to adopt, with the view of securing efficient settlement with the minimum tank capacity.

Apparently the second difficulty has arisen through having insufficient slope on the sides or bottom of the tank. Experience has shown that to ensure a constant flow of sludge from the tank as it deposits, so as to return it in a fresh condition, this slope should be not less than 60 degrees to the horizontal.

In the paper by Mr. Caink, City Engineer of Worcester, a flat bottomed tank is suggested, fitted with a travelling perforated pick-up pipe through which the sludge will flow by hydraulic head.

The outstanding feature of the activated sludge process is the recovery of a considerable proportion of the total nitrogen content in a form available for agricultural purposes. The amount of nitrogen in dried sludge varies from 4 to 6%, dependent on the character of the sewage treated, and it also contains appreciable quantities of phosphate.

The problem of dewatering and drying the sludge so as to render it transportable is therefore of great importance.

Considerable information has been obtained in America (Milwaukee and Chicago) in regard to the probable cost of these operations.

In this connection the following further quotation from Mr. Chalkley Hatton's letter to Mr. Hammond, previously mentioned, is of interest.

"After quite an elaborate experiment on the dewatering and drying of sludge, we find that there are very few problems connected therewith that has not already been solved in industrial establishments where materials of like character must be treated.

There is no difficulty in either one of two kinds of presses (the Berrigan press or the Simplex) of reducing the moisture from 99% to 70%; and there is no difficulty by either the direct or indirect dryer to reduce this moisture from 75% to 10% or lower."

As stated when considering the Milwaukee plant, the cost of this disposal of sludge is given at 13s. 3d. per million gallons, while the anticipated yield from the dried sludge is 25s. per million gallons, with a consequent reduction in the actual cost of treatment of about 12s. per million gallons.

In addition to the use of filter presses for the preliminary treatment of the sludge, there are possibilities in regard to the use of centrifugal machines, or the application of electrical treatment

whereby the sludge particles are granulated and the water readily separated.

A careful study of the conditions requisite for the success of the latter proposal is required. Preliminary experiments by Mr. E. Gaul, M.Sc., encourage the hope that in this direction a practical means of dewatering the sludge may be developed.

In considering this question of sludge disposal, reference should be made to the success of the method adopted by Mr. W. Clifford of the Wolverhampton sewage works, where during the period from September to May the whole of the sludge resulting from the precipitation tank treatment of the Wolverhampton sewage is piped direct to the various farm lands in the vicinity of the works.

The writer suggests this method as a means of utilising to the full the agricultural value of the sludge, in cases where the situation of the outfall works renders it a practical means of disposal.

In this way the bacterial content of the sludge would be maintained, and thus in addition to the proven food value of the sludge the soil would receive whatever advantage is due to bacterial inoculation.

While the actual cost of the process will be governed, of course, by the cost of available power, it will be seen from the foregoing that sufficient information has been already obtained from the operation of large-scale installations to show the practical nature of the activated sludge process, at any rate as applied to the purification of domestic sewage, despite the fact that these early installations have not fully succeeded in meeting the requirements necessary for the complete success of the process.

If, therefore, anticipations in regard to improvement in design of plants are fulfilled and especially if, as appears likely, full advantage can be taken of the value of the resultant sludge, there can be no doubt that the process will demand the serious consideration of all who are concerned with the design of sewage purification plants.

DISCUSSION.

Mr. WATSON said that Mr. Arden had done most excellent pioneer work. The process of air-blowing into sewage was not exactly a new one. It had been first done, many years ago, by Dr. Angus Smith, and by Waring, in America, 20 or 30 years ago, and since then a great deal of useful work had been done. Five years ago, when called upon to advise the Metropolitan Commission of New York on the question of the sewage disposal of New York, attention had been called to the question of air-blowing into sewage, and he had expressed the opinion that it was then out of the question. Investigators in the United States who had since gone more fully into it had come to the conclusion that it was necessary first to activate the sludge. By air-blowing, continued for some hours at a time, a remarkable change was worked in the condition of the liquid itself. No one could suggest that the process was not a practical process, but the question of cost was very important, and had not been very carefully gone into. Mr. Eddy, of Worcester (Mass.), had run two experimental plants in juxtaposition; the one was a percolating filter; the other, a tank through which air was blown. He calculated that the percolating filter was considerably cheaper, notwithstanding the fact that the electric current only cost $\frac{1}{4}$ d. per kw.-hr. There was no doubt as to the results that could be obtained when the power was suitable and good. He pointed out, however, that up to now only experimental plants had been worked.

Mr. E. HALLIWELL drew attention to Mr. Arden's suggestion that, with the exception of disturbance due to excessive quantities of oily matter or to the presence in the sewage of strongly

inhibitory trade effluents, no difficulty had been experienced in obtaining an entirely satisfactory purification of Manchester sewage with an average aeration period of from 4 to 6 hours. Was Mr. Ardern prepared to back that statement up in the case of winter frosts, in the case of breakdown of machinery, in the case of increased flow in wet weather, and other changes which usually obtained at sewage works? The question of the sludge was the essence of the problem. Mr. Ardern had shown in a recent paper that the quantity of sludge obtained by the activated process was twice as much as was produced by any other method. It was to be hoped that the sludge would prove to be of manurial value.

The PRESIDENT said that the question appeared to be one largely of the utilisation of the air. Only 1% of the air was utilised in the process, and when they were dealing with a huge project such as that of sewage it seemed that the cost entailed must be considerable if they could only use that small percentage.

Mr. F. R. O'SHAUGHNESSY expressed the opinion that the process was not past the experimental stage. One important point had been emphasised by the speakers about the process, and that was its vulnerability. Other merits apart, there was no more vulnerable process than the activated sludge process: there was also to be considered the uncontrolled influx of various trade wastes of various kinds. There was the danger of the installation being ruined by flood, or excessive flow. The great drawback to existing processes, by contact or percolation beds, was that they were inelastic or fixed: the advantage of the activated sludge process was its elasticity.

Mr. ARDERN, in reply, said he was prepared to admit that, with regard to this problem, practically nothing of a practical nature had been done in this country. Mr. Chalkley Hatton was responsible for the statement as to the reduction of moisture to 70% by presses—the Berrigan or the Simplex, at Milwaukee. He agreed that ordinary sludge did not lend itself readily to dewatering by pressing. He believed there were possibilities in the electrical treatment of the sludge. If sludge were submitted to low voltage and low amperage current, there was a marked effect in its granulation, and a rapid reduction in the water content. He was not, however, prepared to say what the cost of sludge recovery would be. His view was that winter in this country would have no material effect on the process. They had worked at Withington during winter and summer—in the former when the temperature was below zero; and apart from a reduction of nitrogen content, the value of the sludge had not been impaired. Whilst he appreciated the possible difficulties of trade waste in huge quantity, he did not think it would interfere in the way suggested. He had abstained from giving definite figures as to the cost of the process, but the working of their purely pioneer installations had given such results as to suggest that the process would be able to compete with existing processes. He added that Mr. Eddy did not use two plants working side by side: the figures were arrived at for a definite plant, the activated figures being estimated and not for a plant under his control. To his (Mr. Ardern's) mind Eddy had over-estimated the air costs; they had reduced that cost by one-half in this country.

THE FUTURE OF THE FINE CHEMICAL INDUSTRY.

BY ERNEST W. MANN, B.Sc.(LOND.), F.I.C., Ph.C.

[ABSTRACT.]

Under the past conditions of chemical training, the trained technical research worker has been a

rara avis; under present conditions he is hardly likely to be forthcoming, since the supply of raw material in the person of the graduated student is practically nil.

We are probably all agreed that something in the nature of a post-graduate course is required to enable the student to bridge the very considerable step between the University laboratory and the works, but we are not so well in agreement as to what form the training should take. The State Committee on research advocates the extension of the technological departments already in existence in connection with some of our Universities. Sir Thomas Barclay has proposed the establishment of state research laboratories under joint manufacturing and academic control, working on industrial problems and throwing the results of their work open under licence or royalty. There are many advantages in the latter scheme. One important advantage is the bearing it would have on the economical utilisation of research talent—a very important aspect of the future of technical research—the co-ordination of effort and prevention of waste. It is no doubt common knowledge that since 1914 the problems connected with the manufacture of numerous synthetic chemicals have been under investigation in many laboratories and probably in the end each has arrived at practically the same result.

At the present time, with German competition eliminated, American competition handicapped, and competition of the far East only just perceptible, it is a comparatively easy matter for certain manufactures to be carried on in a small way, and yet profitably. But what chance have they on such lines in the future? Take, for example, salicylic acid, now possibly manufactured by a dozen or more firms in this country with an entire output barely sufficient to supply our home needs; compare this with the output of a single German house before the war, greater than all put together.

Is there room for so much individual effort, and should not some steps be taken to concentrate production and thus to reduce manufacturing costs to such a point as will enable this country eventually to compete with the old-established and large-scale German plants?

There is another possible method by which efficiency can be tested and stimulated, that is by the interchange of manufacturing costs. The knowledge so gained would necessarily be an incentive to efficiency, since no one would rest content until his costs were reduced at least as low as those of any of his competitors.

Another important question on the manufacturing side is supply of trained labour. The shortage of skilled chemical workers is very great indeed, and unless remedied this may handicap us to a very large extent in the future. It may be that under after-war conditions the explosives works may be able to liberate men who have had training in chemical processes, and who will form a nucleus for the formation of a craft of skilled workers. Compulsory attendance at continuation and technical schools, with an obligation on the employer to afford facilities for such attendance will also assist towards this end.

Turning now to the question of markets, the first point that naturally occurs is the relation of the home market to foreign competition, and how far the infant industry is to be protected under post-war conditions. I imagine there will be general agreement that a tariff is essential, for a time at any rate, to prevent the trade being extinguished by the dumping which otherwise would be inevitable. Presumably wholly unmanufactured raw material would be free from duty and the rate of duty would increase proportionately to the complexity of the manufacturing processes involved. Consideration would have to be paid to

the influence of duties on semi-manufactured raw materials on the markets in the colonies and neutral countries, and it may be necessary to arrange for rebate of this duty on goods exported to such markets.

DISCUSSION.

Mr. B. F. HOWARD asked the author for his opinion on the matter of duty-free alcohol, and its probable effect on the English manufacturer in relation to Continental or other competition.

Mr. F. SPROXTON said that the general trend of Mr. Mann's paper appeared to be that in the future the chemical industries would be run principally by large manufacturing firms, and not by small ones. However much that was to be regretted for sentimental or other reasons, he felt they could not escape it. Regarding the question of alcohol, he said that many chemical manufacturers did not really know what facilities could be obtained in duty-free alcohol. If manufacturers wanted the Government authorities to make fresh regulations to help them in their industries, then they must be prepared to devise some scheme to afford the Government protection of their revenue. Manufacturers of fine chemicals would have to contribute towards the constant attendance and supervision of Inland Revenue officials, and here again the large works would have an advantage. Another point was in relation to attendance at Continuation and Technical Schools. If the migration of factories continued as it had done, the supply of educated boys would become a serious question. In large cities little difficulty was experienced in getting boys who had had a certain amount of technical training, and who were prepared to continue it. But if one worked, as he did, in a factory nine miles from a large town there was great difficulty in getting educated lads. He strongly believed in the policy of manufacturers providing facilities by which boys could be technically trained in the works at which they were engaged, and this should be done in their working time, and without any wage deduction. Members of the trained staff might take the classes. Personally he was able to speak of the result of such a system: it had been satisfactory, and had paid for itself over and over again. A certain amount of expense was, of course, involved, but the Board of Education would make a grant on condition that they approved the syllabus, and that the classes were open to the general public. There were at first sight objections to the latter condition, because it appeared that if the public attended, the members of the staff could not be on such intimate terms with the students as they would like, and moreover questions relating to the problems of the factory would have to be restricted. In their own case, however, the public had shown no disposition to attend.

Mr. E. K. SCOTT said that research workers should be protected from exploitation by the financing classes. In the United States what was known as Industrial Fellowships were provided: the system had been introduced at the Kansas University, and it had developed enormously. It seemed to him that some such system was needed in this country. His hope was that the individualistic system would be continued. At the same time he recognised that research work could not be carried on so satisfactorily by small firms as by a central institution, aided by the Government.

Mr. HEAVEN expressed the hope that good results would be obtained from the Ministry of Reconstruction. Was it not possible to continue some of the work done during the war by the Ministry of Munitions, and make it, if necessary, an appendage to the chemical industry; or come to some arrangement whereby individualistic

efforts would not be lessened, but that there would be some form of mutual control?

The PRESIDENT pointed out that this matter was under consideration by the authorities.

Mr. MANN, in reply, expressed his interest in what Mr. Scott had said on the subject of Industrial Fellowships. His firm had not experienced any difficulty, nor had to incur any expense in getting facilities from the Board of Customs for obtaining alcohol. The only condition was that the alcohol had to be denatured under their supervision.

VOTES OF THANKS.

The CHAIRMAN moved a resolution thanking those who had read papers at the meeting. The success of the Congress had been very largely due to the admirable character of the papers, which had been prepared under circumstances of great difficulty.

Mr. F. R. O'SHAUGHNESSY seconded the resolution, which was carried unanimously.

On the motion of Dr. R. H. PICKARD, seconded by Dr. DUNN, a hearty vote of thanks was accorded to Dr. Carpenter for having occupied the chair during the Congress.

VISITS TO WORKS.

On Friday afternoon parties of the members visited the following works, etc.:—Birmingham Gas Department's "Woodall-Duckham" Continuous Verticals and Cyanogen Plant, Windsor Street Gas Works; Birmingham Gas Department's Physical and Metallurgical Laboratories of the Industrial Research Department; King's Norton Metal Company; H.M. Factory, Oldbury (Chance and Hunt, Ltd., Managers); Dunlop Rubber Co.; Birmingham Drainage Board's Sewage Works; Messrs. Kynoch's Works.

EXHIBITION OF CHEMICAL WARE.

During the meeting an interesting exhibition of chemical apparatus and supplies was open in the University buildings. The following firms exhibited specimens of their products:—J. Barsham Green and Son, Doulton and Co., A. Gallenkamp and Co., Ltd., W. and J. George, Ltd., Philip Harris and Co., Ltd., Hind and Laund, Ltd., Kestner Evaporator and Engineering Co., Ltd., Macintyre and Co., Produits Chimiques Centrale, Shanks, Ltd., Southall Bros. and Barclay, Ltd., Standley, Belcher, and Mason, Ltd., Worcester Royal Porcelain Co., Ltd.

The display included examples of glassware, chemical porcelain, filter papers, microscopes, balances, pyrometers, ball mills, and electric furnaces; the various articles shown gave some idea of the great progress that has been made in these industries in Great Britain during the past three years.

London Section.

Meeting held at Burlington House on Monday, June 4th, 1917.

MR. A. R. LING IN THE CHAIR.

SOME OBSERVATIONS ON CRUDE BENZOLS.

BY PERCY E. SPIELMANN, PH.D., B.Sc., F.I.C., AND G. CAMPBELL PETRIE, F.I.C.

The object in view when examining these distillates was to attempt to extract more information from them than is obtainable by means of the retort test—a test which has little to recommend

it, and nothing to support it, scientifically—and at the same time to employ methods which, by their nature, will recommend them to the simplest works laboratory.

For this reason no preliminary treatment was carried out; the samples were examined as received.

A number of coke-oven benzols were analysed by the more recently established methods for content in benzene, toluene, xylene (closely approximate), paraffin, and carbon bisulphide, and these results were compared with certain simple operations to be described. Means for a preliminary "reconnaissance" has thereby been found, giving results more closely accurate than were at first anticipated.

Although from the general and strictly scientific standpoint, empirical and semi-empirical relations may be somewhat distasteful, no apology is offered for drawing attention to such as have been found in the present instance, as they appear likely to be of genuine value to the tar industry.

Benzene and toluene. (A) It has been found that if 100 c.c. of crude benzol be distilled from a distilling flask (columns 50–52) such as is now so widely used in connection with Government tests and specifications, the amount obtained up to 90° C. can be made proportional to the quantity of benzene present, and that from 90° to 120° C., proportional to the quantity of toluene in the sample.

distil at least a litre over a Young 12-pear head, and to note the rise of temperature for every 5 or 10° passing over. In Fig. 2 are shown three such curves, quite ordinary and characteristic of the operation, which indicate from their shape that there is a considerable quantity of benzene and some toluene present; but how much is not obvious—it is not immediately clear how the curve is to be interpreted quantitatively.

Benzene estimation. It has been found that when such curves are plotted in the manner shown on mm. paper (Fig. 2), the horizontal distances between the 5° mark and the point where the curve cuts the 92.5° C. line, gives a close measure of the percentage of benzene present.

The solid constituent in the residue above 170° C. (column 6) was, in each case, naphthalene.

These ranges include such substances as paraffin, and, in the lower fractions, carbon bisulphide also; but the results obtained are not rendered any the less trustworthy, as, in any case, a closer approximation that of 2–3% is not to be expected.

In Fig. 1 is shown the relation between the volume obtained by the distillation test, and the percentage of toluene and benzene present in the sample; there are also drawn the lines for the total quantity of benzene, toluene, etc., obtained by the distillation test, and also by the retort test (columns 48–52).

It was noticed that the distillation test results lie more regularly than the retort test points.

(B) Another mode of examining crude benzols, yielding appreciably more accurate results, is to

number of mm. of maximum deviation of the experimental curve from the smoothed curve shown dotted on the graph.

This relationship is read off by means of the graph (Fig. 3).

Fraction up to 140° C. (columns 52, 53).—A useful coincidence which becomes apparent is that the percentage of liquid obtained by the distillation test up to 120° C. is very closely approximate to the percentage of washed liquid boiling up to 140° C.—a fraction which is of particular interest.

Paraffin (columns 5, 26, 36—39, 40).—This was determined in the fraction up to 90° C. (column 26) by the method of Spielmann and Wheeler (this Jour-

nal, vol. 35, 1916), and the fraction from 90° to 140° C. (columns 36 and 38) by that of Colman (Journal of Gas Lighting, 1915) whilst a direct absorption method (column 40). (Wilson and Roberts this Journal, 1916, vol. 35, page 684), was also used, from which the graph in Fig. 4 was plotted.

It was noticed that the portion of the crude sample fractionated up to 170° C. shows a very varying specific gravity, and that where it was

possible to compare, the specific gravity corresponded fairly well with the quantity of paraffin found by analysis in the washed fraction from 90° to 140° C. (column 40). This is shown in the accompanying graph, which is put forward tentatively, as it is based on only four samples (Nos. 5, 6, 8, 9), quite insufficient for the establishment of a definite rule. But if further work should substantiate it sufficiently accurately, it would provide a simple method of estimating paraffin.

The distribution of paraffin in the fractions up to 90° C., 90°—107° C., 107°—115° C., and 115°—

140° C., did not yield as decisive results as were hoped for, partly on account of the small quantities present in the fractions, and partly because known methods of analysis are not sufficiently precise. It is obvious, however, from the figures in the table columns that in the fractions of rising boiling point there is a distinct diminution in percentage followed by a rise.

Loss on acid washing (columns 7—11).—The fact, that during the distillation of coal, a low temperature favours the production of paraffin, and a high temperature that of aromatic hydrocarbons, is illu-

formed to the general definition for crude benzols, namely, that they should distil over up to 170° C.; most of them contained a considerable proportion of naphthalene (column 6).

For the present discussion, therefore, the fraction up to 170° C. (columns 1, 5) obtained in the laboratory is taken as representing a crude benzol as it should normally be produced.

Sp. grav. at 15.5°C. of crude benzol distillate up to 170°C. over a 5-bulb "Young" dephlegmator head

FIG. 4.

If the quantities of benzene, toluene, and xylene found in the fraction up to 170° C. be plotted against the loss on acid washing of this fraction (Fig. 5), it is seen that the two main constituents do actually occur in their inverse connection with one another; and when these are added together

All this work appears to establish the connection between the various substances found according to the following scheme:—

Pentanes and hexanes

naphthenes (alicyclic hydrocarbons) → higher benzene homologues → lower benzene homologues → benzene → (diphenyl) → naphthalene → anthracene → carbon and gas.

On this basis, therefore, it may be expected that the amount of loss on washing with acid would be inversely proportional to the quantity of aromatic substances present, and that the quantity of benzene and toluene found would be inversely proportional to one another.

In the present case of the crude benzols as obtained from the various makers, very few con-

and combined with the figure of xylene, the total aromatic substances in that fraction show a remarkable constant inverse relationship with the loss on acid washing.

It may be a daring suggestion that the loss on acid washing may be taken as a measure of the three aromatic substances present in such a sample, yet the startling regularity of the plotted line almost compels its acceptance.

It should be pointed out that the sulphuric acid washing may have been more drastic than is considered necessary in a works laboratory, but for analytical purposes this was desirable.

From the figures it appears that the phrase, "loss on acid washing," should be precisely defined in meaning, as there is a considerable difference between the loss occurring after chemical treatment (columns 7, 8) and the total treatment (13, 14), including subsequent distillation.

Meeting held at Burlington House on Monday,
July 2nd, 1917.

MR. ARTHUR E. LING IN THE CHAIR.

THE USE OF BREWERS' YEAST IN BREAD-MAKING.

BY JULIAN L. BAKER, F.I.C.

The possibility of using brewers' yeast in bread-making has in the past attracted much attention, and, indeed, this is not surprising when the selling prices of brewers' and distillers' yeast are compared. Prior to the war distillers' yeast was worth about £30 per ton. Now the relative prices are in the neighbourhood of £2 to £4 and £100.

Apart from the natural desire of brewers to deal profitably with a valuable by-product, the disposal of waste yeast in many cases presents difficulties. Some local authorities refuse to regard yeast as a trade refuse and the brewer not infrequently has

to destroy it at his own expense, or have it carted away and put on the land as a manure.

During the last few years there has been an increasing demand in certain localities for brewers' yeast by yeast-extract manufacturers, and the exigency of the war has greatly increased the output of the extract.

In some centres yeast is dried and used as a constituent of cattle foods. Although the value of yeast is recognised, geographical difficulties, uncertainty of markets, and the low price realised have prevented the brewing industry from developing the profitable disposal of waste yeast.

Many references dealing with the attempted alteration or transformation of brewers' yeast into a yeast suitable for bread-making purposes will be found in the British and foreign journals. In most of the papers which have been published, the variation in the doughing conditions obtaining in bake-house procedure is overlooked. Thus, it is obvious that in a quick doughing process of 3 to 4 hours, a high yeast rate and a strong yeast will be necessary. Most bakers employ a quick doughing process, and the poor repute of brewers' yeast is largely due to its failure under such conditions. With the present statutory flour, given a sufficiently long rise, perfectly good loaves can be made with brewers' yeast alone. The shape of the loaf is an important factor and a set of conditions which will produce a good "Coburg" or tin loaf will be unsuited for the cottage loaf.

A few years ago my colleague, Mr. Hulton, and I carried out a series of investigations on flours used for bread-making, and their behaviour towards brewers' yeasts ("Considerations affecting the 'strength' of wheat flours," this J., 1908, 368; "The behaviour of wheaten flour towards bakers' and brewers' yeast"; *ibid.*, 1909, 778-781; "The toxicity of flours towards *Saccharomyces cerevisiae* (top-fermentation, brewery yeast)"; *ibid.*, 1909, 781-781; "The toxins in cereals," J. Inst. Brewing, 1910, 395-408; Part II., *ibid.*, 1910, 431-435). There is no evidence that the two yeasts are other than the same species of *Saccharomyces cerevisiae*, and an explanation was necessary to account for the difficulty and slowness of brewers' yeast in fermenting flour.

In 1895 Jago (Science and Art of Bread-making, p. 223) recorded experiments in which he shows that brewers' yeast, while quite as capable of fermenting solutions of sugar as distillers' yeast, is relatively inactive towards a mixture of flour and water. H. Lange (this J., 1907, 1104) and F. Hayduck (*ibid.*, 1908, 85) state that many cereals exert a toxic effect on yeast which the presence of certain substances can overcome. In one of our papers (*ibid.*, 1909, 778) we brought forward experimental evidence to prove that the difference in behaviour of brewers' and distillers' yeast during the rising of the dough is due to the susceptibility of the former and the immunity of the latter yeast to the toxins in the flour. We further showed that a partial immunity can be conferred on brewers' yeast by the use of certain salts, thus enabling it to approach, though never to equal, the activity of distillers' yeast when allowed to ferment flour dough under similar conditions.

Our work convinced us that there was no simple process which would confer sufficient strength on brewers' yeast to enable it successfully to ferment the white flours at that time used. In the course of our work we also found that brewers' yeast when grown consecutively three times in a whiskey mash wort, acquired to a large extent the properties of a distillers' yeast, such properties showing little deterioration when the yeast was grown successively three times in brewers' hopped wort. Distillers' yeast would seem to owe its toxin immunity to the fact that it has been produced in an unboiled wort made from cereals, such as barley and rye, containing toxins. Only those cells that can withstand

and reproduce in such an environment survive and this selected immunity is transferred to the resulting crop.

The distribution of the toxin in the barley and wheat corn was a matter of some interest, and experiments showed that the whole meal was less toxic to brewers' yeast than the white or "patent" flour portion, and that the husk portion was anti-toxic in character. With the advent of less highly refined flours containing larger quantities of husk and other non-starchy matters, I thought it likely that brewers' yeast would effect a stronger panary fermentation. Laboratory experiments on the lines described in one of my previous papers (this J., 1909, 788) showed that the gas yield from "statutory flour" fermented with brewers' yeast was considerably higher than from white flour under similar conditions. The anti-toxic character of this flour was, however, insufficient to enable brewers' yeast to be used alone for bread-making involving quick doughing processes. Excellent loaves were made with brewers' yeast and statutory flour by the "long" process, and if the doughing period is immaterial—as, for example, in home baking—there is no reason why brewers' yeast should not be used. (c.f. Table, Scottish Trials.)

In certain economical considerations concerned with the food supplies of this country which became imperative at the commencement of the year, the large quantities of grain (120,000 quarters monthly) used by distillers was the cause of anxiety. To restrict the output from distilleries would entail not only a diminution of the quantity of alcohol required for munitions and other important purposes, but it would also lessen the output of yeast.

If the national interests demanded so extreme a measure, alcohol for munitions could be obtained—as has been suggested in the House of Commons—by rectifying the spirit now in bond. Although this would liberate some grain for food purposes the bakers would be anxious as to their yeast supplies, and it is in the highest degree undesirable that the staple food product of the country should be endangered or prejudiced.

Those responsible for the food supplies naturally inquired if brewers' yeast in any form could be used for bread-making, and I was asked by the Royal Commission on Wheat Supplies as to the possibilities in this direction. I suggested that a portion of the grain used by distillers might be released if satisfactory evidence could be obtained that a blend of brewers' and distillers' yeast was suited for bread-making. I was asked to go into the matter further and carry out the necessary baking trials and report to the Commission. My inquiry lasted some five weeks and the Chairman of the Commission has very kindly allowed me to submit the results to the Society of Chemical Industry.

At first sight the problem would appear to be a fairly simple one, but the doughing conditions in different parts of the country, indeed, in many cases in the same town, vary so widely that to draw safe conclusions from trials in two or three bake-houses is not possible. Moreover, the possible variation in "strength" of brewers' yeast obtained from the various systems of fermentation and the lack of uniformity in the statutory flours were difficulties which had to be contended with. I anticipated reluctance on the part of the bakers to carrying out any trials, bearing in mind the bad reputation brewers' yeast has in the bakehouse, but happily I was mistaken, and I should like to take this opportunity of acknowledging the assistance I received from all of them.

It was arranged that yeast crops from the following fermentation systems should be experimented with:—

(1) Dropping and cleansing. (2) Union. (3) Skimming. (4) Lager. Porter yeast from Ireland was also used.

Brewers' yeast, as has already been stated, can be used in bread-making, without any washing or other treatment. There is, however, some risk of imparting a yeasty and slightly bitter flavour to bread unless the yeast is well washed to remove adhering beer and other impurities, and then submitted to a simple treatment, which not only improves its strength but renders the product uniform. The washing is effected with a very dilute solution of brine and the treatment consists of a short but brisk fermentation in a dilute mash-tun wort. I hope shortly to give a more detailed description of the process to be adopted, which will differ in details from that used in the breweries I visited. I may add that the process is simple and inexpensive, and can be worked with the plant found in an ordinary brewery of good design. The pressed brewers' yeast as a result of this treatment should have lost its characteristic bitter flavour and it ought to keep quite as well as pressed distillers' yeast.

I arranged for the washed and treated brewers' yeast to be distributed to two "machine" bakers and two "hand" bakers in each of the five districts I worked in. Previously I visited the bakers and asked them to conduct baking trials under the same conditions as to yeast, water, and salt rate, and temperature ordinarily obtaining in their bake-houses.

In the majority of cases this was done.

The yeasts generally employed were:—

(A) 33% brewers' yeast with 66% distillers' yeast.

(B) 50% brewers' yeast with 50% distillers' yeast.

(C) 100% brewers' yeast.

(D) 100% distillers' yeast.

Baking trials were carried out at the following centres:—London, the Midlands, West of England, West of Scotland, and East of Scotland. The trials with the Irish porter yeast were made in the West of Scotland.

The loaves were forwarded to the offices of the Royal Commission on Wheat Supplies and criticised independently by two experts appointed by the Commission. These experts were asked to give their opinion as to the palatability, soundness, and flavour of the loaves and as to whether the use of brewers' yeast in admixture with distillers' yeast affected the commercial value of such loaves.

In all some 120 loaves were made, and, to illustrate the nature of the results I have included two typical sets—one from a Midland, the other from a Scottish town.

Before discussing the results it will be germane to refer to an important point which will be raised should the use of mixtures of brewers' and distillers' yeasts be recommended for bread-making. The bakers will require information as to the extent the brewers' yeast has helped in the raising of the dough. Some of them I have questioned consider that the brewers' yeast did no work; other bakers were of the opposite opinion. There is ample evidence that under some conditions, brewers' yeast will make as good a loaf as distillers' yeast and it is therefore evident that brewers' yeast can raise dough. Moreover, an inspection of the results will show that the bread made with mixed yeast of which 33 and 50% was brewers' yeast was not necessarily one-third or one-half as good as compared with the ordinary trade loaf. In a number of instances the experts considered the loaves made with the mixed yeasts superior to the control commercial loaf made with distillers' yeast alone. Neither was the doughing period longer nor the baking slower in proportion to the amount of brewers' yeast in the mixed yeasts.

I endeavoured, with the assistance of my colleague, Mr. Hulton, to obtain experimental evidence of the gas yields obtained when mixtures of brewers'

and distillers' yeast were allowed to ferment aqueous suspensions of flours under the conditions described in a former paper (this J., 1909, 778); 20-grm. portions of statutory flour were made into thin pastes with 50 c.c. of a 0.5% solution of sodium chloride

the mixture of yeasts contains more than 50% of brewers' yeast the volume of CO₂ evolved is higher than the sum of the yields of the constituents. Thus a mixed yeast consisting of 20% brewers' yeast and 80% distillers' yeast ferments flour in

and the weighed quantities of yeast mixed in. The fermentation was conducted at 110° F., the following gas yields being recorded at the expiration of 4 hours.

Weight of yeast.	c.c. CO ₂ .
0.5 grm. distillers' yeast	207
0.5 grm. brewers' yeast	25
1.0 grm. distillers' yeast	260
0.5 grm. distillers' yeast	262
0.5 grm. brewers' yeast	1

It will be noticed that 1 grm. of a mixture of equal parts of brewers' and distillers' yeast has the same fermentative power as 1 grm. of distillers' yeast alone. If the two yeasts worked independently the yield should have been the sum, viz., 207+25=232, whereas the volume found was 262 c.c. Similar results were obtained in other experiments. If

exactly the same way as an equal weight of distillers' yeast and if the volumes of CO₂ be plotted against time, the respective curves are superimposed.

The evidence afforded by these results, taken in conjunction with the baking trials, proves fairly conclusively that when distillers' yeast is mixed with brewers' yeast the latter yeast does not act merely as a diluent but contributes its *quota* or more to the fermentation of the dough.

Before any Public Authority can suggest or recommend the use of mixtures of distillers' and brewers' yeast to bakers some evidence will be required as to the amount of brewers' yeast available for this purpose.

At the present time the output of beer is limited to 10,000,000* barrels per annum. The yeast crop varies with the system of fermentation and the kind of beer brewed.

*Since this paper was written the barrellage has been increased by one-third.

In general terms every standard barrel of wort of a gravity of 1055° will produce 4 lb. of yeast, of which quantity 1 lb. will be required for pitching purposes. The 3 lb. surplus will amount to about 250 tons weekly.

Some years ago I had occasion to collect data as to the amount of waste yeast in London. The output of beer in the United Kingdom was then (1900) slightly over 39,000,000 barrels. The following quantities of waste yeast could at that time be obtained from eight of the leading London breweries:

Brewery A	30 tons per week.
" B	20 " "
" C	20 " "
" D	15 " "
" E	12 " "
" F	10 " "
" G	9 " "
" H	8 " "
	—
	124 " "

On a basis of 10,000,000 barrels probably 35 to 40 tons of yeast could be collected weekly in the Metropolitan area.

It should be borne in mind that at the present time the demand for brewers' yeast is small, so much so that in many instances it does not pay brewers to use yeast presses. But, if brewers' yeast can find a use in the bread-making industry, there will be a strong incentive for every brewer to wash and treat his waste yeast as its value will then probably rise to £15 or £20 or more per ton.

CONCLUSIONS.

The following conclusions may be drawn from this enquiry:—

(1) That brewers' yeast from any part of the United Kingdom is suitable for mixing with distillers' yeast. A mixture of brewers' and distillers' yeast will effect a satisfactory fermentation of dough. In such mixtures the brewers' yeast does not act as a diluent but is contributory to the fermentation.

It would appear that in the case of pan (tin) bread a mixture of equal parts of brewers' and distillers' yeast can be used. With the "Coburg" type of loaf one of the judges was of the opinion that whilst sound bread may be made with 50% of brewers' yeast, 33% should not be exceeded.

(2) When mixtures of the two yeasts containing 33 or 50% of brewers' yeast are used, the doughing period will be slightly prolonged if the yeast rate is low. For example a five-hour dough may be increased by one hour.

(3) Under the ordinary "quick doughing" process brewers' yeast by itself is useless. With a "slow dough" good loaves were made using only brewers' yeast.

(4) If, in the national interests, it should be decided to restrict the quantity of distillers' yeast supplied to bakers, the deficit could be replaced by brewers' yeast within the limits referred to in (1) without seriously interfering with existing conditions of manufacture or altering the commercial value of the loaves.

On the other hand if bakers were to adopt "slow doughing" methods the quantity of distillers' yeast now used could be reduced possibly even to ½ lb. per sack of flour of 280 lb. From what I have been able to gather there would be grave objections brought forward by the bakers to this course, one of the most important being the question of labour.

(5) Brewers' yeast by itself will produce palatable loaves, so that, in the case of emergency, it could be used. The drawbacks referred to at the

end of the last paragraph would however apply in even greater force.

(6) Some 700 tons per week of distillers' yeast is used for bread-making.

With the present barrelage of beer about 200 to 250 tons of brewers' yeast would be available for the baker at a price much lower than is paid for distillers' yeast.

(7) My own opinion, based on the results of the enquiry I have just concluded, is that the bakers would be able to use a mixture of equal parts of brewers' and distillers' yeast without any serious inconvenience to their trade or disadvantage to the public. If the 200 to 250 tons of brewers' yeast were to replace an equivalent amount of distillers' yeast, a very considerable quantity of grain being used to make the latter would be liberated for human consumption.

DISCUSSION.

Mr. T. WATSON LOVIBOND said that it was a well-known fact that brewers' yeast had been used for bread-making in former years. He thought that there was an absence of uniformity of conditions in the experiments described, and he could not help feeling some lack of confidence in the opinions given by the experts. The mode of comparison adopted seemed hardly fair.

Mr. KIRKLAND said that, speaking as a practical man, he thought that bakers could manage very well without brewers' yeast. He could not help thinking that Mr. Baker had been hampered in his experiments by being at the mercy of people who were unscientific. He thought that useful results were more likely to be obtained in small bakeries than in large ones. With regard to the opinions of experts, he would point out that loaves might be made to have any desired appearance, in spite of the fact that they had been baked under different conditions and with different yeasts. Could the author explain why distillers who made bakers' yeast used brewers' yeast for seeding? There was no difficulty in using brewers' yeast for baking, but it was slower and the plant in the United Kingdom would have to be increased if the baker had to depend upon it entirely. The Scottish bakers in former years made their barn for baking purposes from brewers' yeast.

Mr. W. WATERS BUTLER recalled lectures on bread-making by Sir William Tilden given at Birmingham over thirty years ago. The views held on the subject of bread-making were conflicting. Some contended that neither brewers' nor distillers' yeast was necessary. It was quite certain that thirty or forty years ago nothing but brewers' yeast was used by the baker, and that the loaves kept moist for a longer period and were of a better flavour than those of to-day. He asked Mr. Baker if any "improvers" had been used in the flours from which the loaves he had described were made.

Mr. BAKER replied that "improvers" had not been used.

Mr. BUTLER, continuing, said that he had been shown what the baker described as a good loaf which had been made from the yeast of his own brewery, and he had subsequently ascertained that the fermentation from which the particular yeast had been derived had been "dressed" with malt flour. He thought that the use of raw grain and sugars in modern brewing had exerted a weakening effect on the yeast. He hoped Mr. Baker would continue his experiments and that they might lead to an increase in the use of brewers' yeast for bread-making.

Mr. W. B. OAKDEN asked whether, if distilling was entirely suppressed by prohibition, there

could be found a substitute for yeast as suitable for bread-making.

Mr. WATKINS doubted if the difference between bakers' and brewers' yeasts was due to toxins in the flour. He thought that brewers' yeast had insufficient proteolytic power to deal with unpeptonised material such as gluten in flour and hence the weakness of brewers' yeast in dough fermentation: bakers' yeast on the other hand was sufficiently rich in proteolytic enzymes to peptonise gluten and thus furnish itself with the peptones requisite for its healthy growth and reproduction.

Mr. ANDERSON (Vice-Chairman of the Wheat Commission) said that he had been much interested in watching the progress of Mr. Baker's work. He thanked the Society for their hospitality and touched upon the close connection between the scientific work done by the members and the task of the Royal Commission.

Dr. G. C. DIXON (Royal Commission on Wheat Supplies) said that the results of the experiments carried out by Mr. Baker on the use of brewers' yeast in bread-making had already been carefully considered by the Royal Commission. They were now anxious that brewers' yeast should be used for that purpose to as large an extent as possible. Information had often been received to the effect that one of the objections to brewers' yeast for baking was that there was a risk of its not keeping sufficiently well to allow for its transport from one part of the country to another. They were, therefore, still somewhat doubtful as to the best method of using brewers' yeast effectively, and wished to know whether any of the chemists present had ever considered the possibility of mixing brewers' yeast with distillers' yeast during the fermentation process, and whether that would be an effective way of improving its keeping qualities.

Dr. FYLEMAN said that he had carried out some satisfactory experiments in bread-making with brewers' yeast previously washed with a dilute salt solution.

The CHAIRMAN said that there could be no doubt that the two yeasts, namely, that commonly used by bakers and that produced by brewers, were identical as regards species, and he hoped that Mr. Baker in continuing his experiments would find a means of converting one into the other by some simple means. With regard to the use of brewers' yeast, Mr. Baker had assumed that an increase of 4 lb. per barrel was obtained in the brewery, leaving a surplus of 3 lb. per barrel over and above that required for subsequent pitching. He would remind them that the 10,000,000 barrels allowed to be brewed between now and November would be increased in bulk considerably owing to a reduction in gravity, but this reduction in gravity would mean a reduction of yeast outcrop. The question of securing sufficient yeast for pitching was one of the most pressing to brewers at the present time. It was well known that the best yeast was obtained from an 18 to 20 lb. beer. The outcrop from a beer at higher or lower gravity was less satisfactory both in quality and yield.

Dr. L. T. THORNE said that in his experience previous aeration of brewers' yeast in sweet wort much increased the rapidity of its action towards dough.

Mr. W. SCOTT, speaking as a brewer, said that although brewers' and distillers' yeasts were of

the same species each had gone through such very different treatment that they were not interconvertible as far as bread-making was concerned. He had found that if brewers' yeast were washed with dilute salt solution in the pressed state it kept better. By using a much larger quantity of brewers' yeast the speed would be increased and at the same time valuable nutritive matter would be added to the bread.

Mr. KERSHAW asked whether the so-called German yeast was a product of the brewery or distillery.

Mr. E. HILL said that it seemed to him that the solution of the problem of the utilisation of brewers' yeast depended largely on the question of nutrition. If one yeast cell were added to a solution of cane sugar, the yeast cell died; if, however, several yeast cells were added to cane sugar solution some lived and grew, the reason for this being that the surviving cells obtained the necessary nourishment from the other yeast cells which had died. If the table of results were examined it would be seen that while only a small quantity of CO₂ was obtained from the brewers' yeast, a mixture of equal parts of brewers' yeast and distillers' yeast generated more gas than the total gas obtained when each quantity of the respective yeast was fermented separately. This was probably due to the fact that a greater part of the brewers' yeast died, and acted as a manure for the distillers' yeast and remaining brewers' yeast, which then grew quickly to give a good yield of gas. He would therefore suggest that experiments be made using a mixture of brewers' yeast with some fertiliser such as killed yeast cells, or the liquid obtained by the autolysis of yeast.

Mr. BAKER, in reply, reminded Mr. Lovibond that the baking trials had been carried out under the ordinary conditions obtaining in the respective bakehouses, the only factor which varied having been the yeast. The essential object of the investigation had been to ascertain if a blend of the two yeasts could produce sound commercial loaves and the bakers had not been asked to do their best with the mixtures of brewers' and distillers' yeasts and brewers' yeast alone.

The experts had had the loaves before them and they had judged separately and without knowledge of the baking conditions. Under such circumstances it might be fairly concluded that genuine opinions, free from any bias, had been expressed.

He would like to take this opportunity of thanking Mr. Kirkland for several suggestions made during the course of the investigation and for baking trials carried out at the Borough Polytechnic. He believed that the distillers who made yeast had been most careful to select their "seed" from previous distillery fermentations.

Brewers' yeast, like distillers' yeast, possessed proteases and there seemed no reason for believing that the one yeast differed from the other to any marked extent in enzymic activity.

He doubted if there would be any advantage in Dr. Dixon's suggestion of carrying out fermentations with the mixed yeasts. Raw brewers' yeast would not keep well, but if it were washed and treated it would have the same life as distillers' yeast.

He did not share Mr. Hill's views as to the brewers' yeast dying and affording nutriment to the distillers' yeast. In such mixed fermentations there was no undue proportion of dead yeast cells.

Official Notices.

CONTRABAND OF WAR.

A Proclamation, dated 2nd July, adds to and amends the lists of articles to be treated as contraband of war, and consolidates and re-issues them in alphabetical order, as follows:—

Schedule I.—Absolute contraband. Abrasive materials (see "Emery"). Acetic acid and acetates. Acetic anhydride. Acetic ether. Acetones, and raw or finished materials usable for their preparation. Albumen. Alcohols including fusel oil and wood spirit, and their derivatives and preparations. Aluminium, and its alloys, alumina, and salts of alumina. Ammonia. Ammonia liquor. Ammonium salts. Aniline and its derivatives. Antimony, and the sulphides and oxides of antimony. Apparatus which can be used for the storage or projecting of compressed or liquefied gases, flame, acids, or other destructive agents capable of use in warlike operations, and their component parts. Arsenic and its compounds. Arsenical ore. Asbestos. Asphalt. Balata (see "Rubber"). Barium chlorate and perchlorate. Barium sulphate (barytes). Bauxite. Benzine (see "Mineral oils"). Benzol and its mixtures and derivatives. Bitumen. Bleaching powder. Bone black. Bones in any form, whole or crushed; bone ash. Borax, boric acid, and other boron compounds. Bromine. Cadmium, cadmium alloys, and cadmium ore. Calcium acetate, nitrate, and carbide. Calcium sulphate. Camphor. Capsicum. Carbolic acid (see "phenol"). Carbon disulphide. Carbon, halogen compounds of. Carborundum (see "Emery"). Carbonyl chloride (see "Phosgene"). Caustic potash. Caustic soda. Celluloid. Cerium, and its alloys and compounds. Chloride of lime. Chlorides, metallic (except chloride of sodium), and metalloidic. Chlorine. Chromium and its alloys, salts, compounds and ores. Cobalt and its alloys, salts, compounds and ores. Copper pyrites, and other copper ores. Copper, unwrought and part wrought; copper wire; alloys and compounds of copper. Cork, including cork dust. Corundum (see "Emery"). Cotton, raw, linters, cotton waste, cotton yarns, cotton piece-goods, and other cotton products capable of being used in the manufacture of explosives. Cresol and its mixtures and derivatives. Cyanamide. Diamonds suitable for industrial purposes. Electrolytic iron. Emery, corundum, carborundum, and all other abrasive materials, whether natural or artificial, and the manufactures thereof. Explosives, materials used in the manufacture of. Explosives specially prepared for use in war. Fatty acids. Felspar. Ferro-alloys of all kinds. Ferro-silicon. Fibres, vegetable, and yarns made therefrom. Flax. Formic acid and formates. Formic ether. Fusel oil (see "Alcohols"). Gases for war purposes, and materials for production thereof. Glycerine. Goldbeaters' skin. Gutta-percha (see "Rubber"). Haematite iron ore. Haematite pig-iron. Hair, animal, of all kinds, and tops, and noils and yarns of animal hair. Hemp. Hides of cattle, buffaloes, and horses. Hydrochloric acid. Incendiary materials for war purposes. Insulating materials, raw and manufactured. Iodine and its compounds. Iridium and its alloys and compounds. Iron (electrolytic). Iron pyrites. Kapok. Lead and lead ore. Leather, undressed or dressed, suitable for saddlery, harness, military boots, or military clothing. Leather belting; hydraulic leather; pump leather. Light producing materials for war purposes. Lithium (see "Strontium").

Lubricants. Manganese and manganese ore. Manganese dioxide. Mercury. Metallic sulphites and thiosulphates. Mineral oils, including benzine and motor-spirit. Molybdenum and molybdenite. Monazite sand. Motor-spirit (see "Mineral oils"). Naphtha (see "Solvent naphtha"). Naphthalene and its mixtures and derivatives. Nickel and its alloys, salts, compounds and ores. Nitrates of all kinds. Nitric acid. Oleum (see "Sulphuric acid"). Osmium and its alloys and compounds. Oxalic acid and oxalates. Palladium and its alloys and compounds. Phenates. Phenol (carbolic acid) and its mixtures and derivatives. Phosgene (carbonyl chloride). Phosphorus and its compounds. Photographic films, plates, and paper, sensitised. Pitch. Platinum and its alloys and compounds. Potassium salts. Powder specially prepared for use in war. Prussiate of soda. Quebracho wood (see "Tanning substances"). Quillaia bark. Ramie. Resinous products. Rhodium and its alloys and compounds. Rubber (including raw, waste, and reclaimed rubber, solutions and jellies containing rubber and any other preparations containing balata and gutta-percha, and the following varieties of rubber, viz.: Borneo, Guayule, Jelutong, Palembang, Pontianac, and all other substances containing caoutchouc), and goods made wholly or partly of rubber. Ruthenium and its alloys and compounds. Sabadilla seeds and preparations thereof. Selenium. Silk, artificial, and the manufactures thereof. Silk, in all forms, and the manufactures thereof; silk cocoons. Skins of calves, pigs, sheep, goats, and deer. Smoke-producing materials for war purposes. Soap. Soda lime. Sodium. Sodium chlorate and perchlorate. Sodium cyanide. Solvent naphtha and its mixtures and derivatives. Starch. Steel containing tungsten or molybdenum. Strontium and lithium compounds, and mixtures containing the same. Sulphur. Sulphur dioxide. Sulphuric acid; fuming sulphuric acid (oleum). Sulphuric ether. Talc. Tanning substances of all kinds, including quebracho wood, and extracts for use in tanning. Tantalum and its alloys, salts, compounds and ores. Tar. Thiosulphates (see "Metallic sulphites"). Thorium and its alloys and compounds. Tin; chloride of tin; tin ore. Titanium and its salts and compounds; titanium ore. Toluol and its mixtures and derivatives. Tungsten and its alloys and compounds; tungsten ores. Turpentine (oil and spirit). Uranium and its salts and compounds; uranium ore. Urea. Vanadium and its alloys, salts, compounds and ores. Vegetable fibres (see "Fibres"). Waxes of all kinds. Wire, steel, and iron. Wood spirit (see "Alcohols"). Wood tar and wood tar oil. Woods of all kinds capable of use in war. Wool, raw, combed, or carded; wool waste; wool tops and noils; woollen or worsted dyaruss. Xylol and its mixtures and derivatives. Zinc and its alloys. Zinc ore. Zirconia. Zirconium and its alloys and compounds.

Schedule II.—Conditional contraband. Algæ, lichens, and mosses. Casein. Charcoal (see "Fuel"). Explosives not specially prepared for use in war. Foodstuffs. Forage and feeding-stuffs for animals. Fuel, including charcoal, other than mineral oils. Gelatine, and substances used in the manufacture thereof. Glue, and substances used in the manufacture thereof. Lichens (see "Algæ"). Mosses (see "Algæ"). Oils and fats, animal, fish, and vegetable, other than those capable of use as lubricants, and not including essential oils. Oleaginous seeds, nuts, and kernels. Powder not specially prepared for use in war. Yeast.

PROHIBITED EXPORTS.

By an Order-of-Council dated July 13th, 1917, carnauba wax is removed from Class (C) to Class (A) in the list of prohibited exports (see this J., 1917, 523), and the following headings are added:—(A) Potassium bicarbonate and mixtures containing it; (C) sera, except anti-tetanus serum; (C) sodium sesquicarbonate; (A) castor oil and articles and mixtures containing it.

CREOSOTE AND OTHER TAR OILS.

RESTRICTIONS ON USE AND ON DEALINGS.

The Minister of Munitions has made an Order, under date 13th July, relative to the use of creosote and other oils produced from the distillation of coal tar. The Order is to the following effect:—

For the purposes of this Order the expression "creosote" shall mean creosote, green oil, sharp oil, and any oil produced from or containing an admixture of oil produced from the distillation of coal tar, or any of them.

No person shall as from 13th July until further notice, except under and in accordance with the terms of a licence issued under the authority of the Minister of Munitions, use any creosote (whether as a solvent or otherwise) for or in connection with:—

(i.) The water-proofing, preservation, or treatment of timber or wood of any kind or description.

(ii.) The manufacture, repair, preservation or treatment of any road or path in the United Kingdom, or any part of such road or path.

No person shall as from 13th July until further notice offer to sell, or except for the purpose of carrying out a contract in writing existing prior to such date for the sale of creosote, enter into any transaction or negotiation in relation to the sale of creosote, except under and in accordance with the terms of a licence issued under the authority of the Minister of Munitions.

All applications for licences under this Order should be made to the Director General of Munitions Supply, Ministry of Munitions, Whitehall Place, London, S.W.1., and marked "Creosote Licence."

The Minister of Munitions has made a further order, dated 13th July, requiring all users or consumers of creosote oil, green oil, sharp oil, anthracene oil, or other oils with a specific gravity of 1.000 or more, distilled from coal tar, and all oils with a specific gravity of 0.950 or more distilled from other tars, to furnish the following particulars, within fourteen days from the above date, to the Controller of Mineral Oil Production, M.P.S.3, 8, Northumberland Avenue, London, W.C. 2:—

1. The source or sources from which their present supply is obtained.

2. The quantities of such oils used or consumed by them from 1st January, 1917, to 30th June, 1917.

3. The quantities of such oils which it is anticipated will be used or consumed by them from 1st July, 1917, to 31st December, 1917.

4. Full details of the purposes for which such oils have been or are intended to be used or employed.

IMPORTS INTO FRANCE AND ALGERIA.

The *Board of Trade Journal* of July 26th contains a list, reprinted from the *Journal Officiel* of July 13th, showing the various goods which may be imported into France and Algeria without licence, and a list of articles formerly allowed to be imported without licence but not now included in this list.

CARNAUBA WAX.

The Army Council gives notice that they intend to take possession of all stocks of carnauba wax, excepting stocks of less than two tons, that are at present or may hereafter arrive in the United Kingdom. All persons having in their custody or control any such stocks are required to make a return thereof, with full particulars of quantity, description and cost price, to the Director of Army Contracts, Room 79, Imperial House, Tothill Street, London, S.W.1.

London Section.

Meeting held at Burlington House on Monday, July 2nd, 1917.

MR. A. R. LING IN THE CHAIR.

DETERMINATION OF PHENOL IN COMMERCIAL CRESYLIC ACID.

BY J. J. FOX, D.S.C., AND M. F. BARKER, B.S.C.
Government Laboratory, London.

It has recently become of importance to ascertain the amount of residual phenol left in cresylic acid after the bulk of the crystallisable phenol has been removed in the factory. The matter is not so simple as might appear at first sight and it has engaged the attention of many workers. Of the various methods proposed from time to time only three need be mentioned here. A process which promised well is that suggested by Schryver (this J., 1899, 18, 553) who employed sodamide. This substance is acted on by the three cresols in such a manner that the same amount of ammonia is produced by the interaction of equal weights of the cresols and sodamide, whereas an equal weight of phenol gives more ammonia. Unfortunately the difficulties encountered under ordinary laboratory conditions render the process difficult to work. J. M. Weiss* (J. Franklin Inst., 1912; see this J., 1913, 692) made a number of experiments on mixtures of phenol with varying proportions of the cresols, and on the basis of his results devised a process which probably gave a more accurate measure of the phenol present in a mixture than any of the older processes. Still more recently R. Masse and H. Leroux (Comptes Rend., 1916, 163, 361; see this J., 1916, 1148) gave an account of a method which furnishes a measure of the amount of crystallisable carbolic acid likely to be obtained under ordinary working conditions. The process requires 3 or 4 litres of tar acid for the test. The last two methods appear to assume that all the phenol is collected in the fraction of the tar acids distilling up to about 200° C. and that the distillate at various temperatures is of constant composition. Our tables show that this is by no means the case. In view of this the method described below was worked out and has been used by us for some time past. It depends on the fact that the addition of a suitable proportion of *o*-cresol furnishes a mixture from which the whole of the phenol can be recovered in the first fraction of the distillate. The proportion of *o*-cresol to be added in an estimation is ascertained by a preliminary distillation of the tar acids. The volume of the cresylic acid distilling between 195° C. and 202° C. is noted, an equal volume of *o*-cresol is added to the original tar acids, and the process is carried out with this mixture in the manner described later.

The solidifying point of the tar acid distillate before the addition of *o*-cresol is not a certain measure of the proportion of phenol present

* Since this paper was communicated, an important contribution to the subject has been made by J. M. Weiss and C. F. Downs (J. Ind. Eng. Chem., 1917, 9, 569; see this Journal, p. 861).

inasmuch as the three cresols yield totally different freezing point curves when mixed with phenol. A slight description of these curves* will make this clear. *o*-Cresol and phenol yield a freezing point curve which falls regularly as the proportion of cresol is increased up to about 30%; from this point up to about 65% cresol the curve is almost horizontal and then rises regularly. *p*-Cresol and phenol, according to Lunge, yield a curve consisting of two branches (G. Lunge, Chem. Ind., 1885, page 6, and Lunge, "Coal Tar and Ammonia," Part I, 1916, p. 277) and we have confirmed this. *m*-Cresol yields a peculiar curve containing two well-defined minima; a slight break occurs with 33% of cresol, and sharp changes in direction with 49% and 94% and a maximum point with about 66% cresol. Two points are brought out by these curves: (1) the difficulty of utilising any one of the cresols for the determination of the phenol present from the solidifying points, and (2) the necessity of utilising only those portions of the curves which correspond to mixtures rich in phenol. For this reason we add to the distillate sufficient pure phenol to produce a mixture containing at least 80% of phenol. The curves for the solidifying points which we use have been constructed in three ways, namely (1) from mixtures of *o*-cresol and phenol directly, (2) from a distillate collected up to 195°C. obtained from a mixture of pure cresols in the proportions 70% *o*-cresol, 15% *m*-cresol, and 15% *p*-cresol, and (3) from the corresponding distillates obtained from about one hundred samples of commercial cresylic acid which showed no phenol and in which the first fractions of tar acid distilling over were rejected. In practice it was found that the three curves lie very close to each other, especially (2) and (3), and that the errors introduced by using any of the three curves are of little importance for this kind of work. The following results show the degree of accuracy with which we have been able to estimate the phenol in cresylic acid.

% Phenol in original mixture.	% <i>o</i> -Cresol.	% Other phenols present.	% Phenol found.
4.7	66	<i>m</i> - and <i>p</i> -Cresols } 29.3	4.8
10.0	55	<i>m</i> - and <i>p</i> -Cresols } 35	9.7
10.2	45	<i>m</i> - and <i>p</i> -Cresols } 30.4	9.5 (after adding <i>o</i> -cresol)
		Xylenols } 14.4	
14.0	0	<i>m</i> - and <i>p</i> -Cresols } 86	10.9 (before adding <i>o</i> -cresol)
			13.7 (after adding <i>o</i> -cresol)

The following are the data for three curves of solidifying points which are used by us:—

% Phenol.	Solidifying points (°C.).		
	(1) <i>o</i> -Cresol alone.	(2) Mixture of pure cresols.	(3) Commercial distillate.
100	40.2	40.2	40.1
95	37.6	37.4	37.4
90	34.9	34.6	34.5
85	32.2	31.9	31.7
80	29.3	29.2	28.9

The curve of Masse and Leroux (*loc. cit.*) is only slightly different from any of the above. They give in their paper the following data:—100% phenol—40.2°C., 66% phenol—20.0°C.

The effect of *o*-cresol and *p*-cresol on the solidifying point is obviously eliminated by the process here

described. It should be noted that the amount of phenol determined by this method is the *total* amount present and not necessarily the quantity of phenol *extractable* from the mixture in a pure state, nor is the process intended to be a substitute for Lowe's method of assaying crude carboic acid. Good commercial *o*-cresol is as a rule sufficiently pure for use without further treatment, but it is desirable to assay it by this process as if it were a mixture and make the necessary allowance. Our practice is to dissolve the *o*-cresol in excess of sodium hydroxide solution (sp. gr. 1.2) and remove naphthalene, etc., by distillation with steam. The alkaline liquid is acidified and the separated *o*-cresol is fractionally distilled. The first portions of the distillates are rejected and the middle constant boiling fraction is collected separately for use. It should have the physical characteristics described here.

Physical constants of the cresols used in constructing the tables.

	<i>o</i> -Cresol.	<i>m</i> -Cresol.	<i>p</i> -Cresol.
Boiling point at 760 mm.	191.8°	202.1°	202.5°
Freezing point	30.1°	—	36.0°
Sp. gr. 15.5° C.	1.0516	1.0387	1.0388
Sp. gr. 25° C.	1.0449	1.0334	1.0334
Refractive index* at 40° C. (n_D)	1.53719	1.53322	1.53187
$d\rho/dt$	—0.00047	—0.00040	—0.00038

The *o*-cresol used has a slightly higher boiling point than that described by Perkin (J. Chem. Soc., 1896, 69, 1182) and a slightly higher specific gravity at 25°. The higher boiling point rules out phenol as a possible impurity and the higher specific gravity shows that *m*-cresol, *p*-cresol, and xylenols are not present in our specimen.

The process used for determining the boiling points of the mixtures is that described in Young's "Fractional Distillation," 1903 edition, page 58, but the flask employed was similar to that used by Northall-Laurie (Analyst, 1915, 40, 384).

The cresols absorb moisture fairly readily and on this account any apparatus used is, wherever possible, attached to drying tubes containing calcium chloride.

It will be noticed that there are slight discrepancies between the physical constants of the chemically pure cresols as described in the literature and those given for the same cresols in our tables. The deviations are small and do not affect the accuracy of the tables to any degree of practical importance. The differences arise from the fact that the chemically pure cresols cannot be prepared in quantities sufficient for any lengthy series of experiments except by very laborious processes. The specimens actually used in the specific gravity and boiling point determination were prepared from the commercially pure substances by fractional distillation and crystallisation, or by sulphonation and recovery of the phenol from the sulphonic acids.

Process.—100 c.c. of the cresylic acid is shaken with 200 c.c. of sodium hydroxide solution (sp. gr. 1.2) and the liquid is treated with ether to extract naphthalene and neutral taroils. Three extractions with the ether are made, using 20 to 30 c.c. of ether each time, but more ether may be used if found necessary to obtain a sharp separation. The ether is washed with a little water once or twice and the washings are added to the strong soda solution from which the ether may be expelled by warming gently. The cooled soda solution is acidified carefully with sulphuric acid (1:1), the containing vessel being kept cold in

* These values are due to Mr. S. C. Bradford, B.Sc., of the Science Museum, South Kensington, to whom we are indebted for a large amount of work on the refractive indices of phenol and cresol mixtures.

* The complete curves are of considerable interest in other respects and will be dealt with fully in another connection.

running water or by immersion in a bath of cold water. The tar acids are allowed to separate and the clear lower aqueous layer is removed and extracted with ether, the ethereal solution being added to the main quantity of tar acids. Free sulphuric acid is removed from this ethereal solution by washing it with nearly saturated sodium sulphate solution. The ethereal solution is now dried by adding calcium chloride in small pieces. The calcium chloride must be freshly ignited and allowed to cool in an atmosphere of carbon dioxide. The dried liquid is transferred to a flask, the calcium chloride washed with dry ether, and the liquid distilled. To remove all the ether the tar acids must be heated to about 120° C.

The tar acids are now distilled and collected in fractions. The most convenient form of apparatus for 100 c.c. of tar acids is a 300 c.c. round-bottomed flask with a neck about five inches long fitted with a Young's still-head with four-pear bulb. If long-necked flasks are not available then an eight-pear bulb (or a rod and disc column) still-head should be used. A short bulb thermometer graduated in 0.5° C. from 90° upwards is used, the centre of the bulb of the thermometer being 1 cm. below the side tube of the fractionating column. Corrections for emergent stem are made as usual. The first distillation is carried up to 210° C. (Distillate A) when all the phenol, practically all the cresols, and a little xylol comes over. There should not be more than traces of water if the drying of the ether has been efficiently conducted. This fraction is redistilled and the first fraction up to 195° C. is collected separately in a tared vessel and weighed. The fraction from 195° C. to 196.5° C. is also collected separately. Provided the fraction distilling up to 195° amounts to about 50% of the volume of the tar acids which have been collected in the first fractionation (A), the phenol can be estimated at once by the freezing-point method described below. If, however, this fraction is much less than 50%, sufficient pure *o*-cresol is added to the fraction (A) to yield at least 50% of distillate up to 195°. The amount of *o*-cresol to be added will depend upon the amount of distillate up to 195° C. obtained from the redistillation of fraction (A). From our experience we find that an amount of *o*-cresol equal in volume to the fraction of (A) distilling between 195° C. and 202° C. suffices. The fraction up to 195° C. in whatever manner obtained, is weighed. The traces of moisture picked up during the operations are removed by adding ignited calcium chloride to the weighed distillate. The freezing point of this distillate is now determined after the addition of sufficient phenol to an aliquot portion to yield a mixture containing at least 80% of phenol.

About 15 grms. of the liquefied mixture of phenol and distillate is required for the determination of the solidifying point. The liquid is placed in a test-tube 6 in. × $\frac{3}{4}$ in. and this is inserted into an air-bath consisting of another tube 6 in. × $1\frac{1}{4}$ in. The apparatus is placed in a bath of water at about 20° C. The solidifying point is then taken, a thermometer graduated in tenths of a degree being used. The liquid is stirred regularly—once a second—with a stout copper wire stirrer. Excessive supercooling must be avoided. At the solidifying point the thermometer rises to a maximum and remains stationary for some time. This point is taken as the solidifying point. Reference is now made to the curve of solidifying points of known mixtures of phenol and cresols for the amount of phenol in the mixture. To estimate the amount of phenol in the original sample the following calculation is made:—

A = Aliquot portion of distillate up to 195° C.

B = Amount of phenol added to yield the mixture containing at least 80% of phenol.

C = Amount of phenol determined from the solidifying point in the mixture.

The amount of phenol in A is (C - B). If the total weight of distillate up to 195° C. is W the percentage of phenol in the original sample is given by:—

$$\frac{W \times (C - B) \times 100}{A \times 100 \times \text{Specific gravity}}$$

if the 100 c.c. of the sample originally taken was measured out at 15.5° C. which is the temperature of the determination of the specific gravity.

The distillate collected between 195° C. and 196.5° C. is tested for phenol with bromine water as described below.

The presence of phenol in the distillate up to 195° C. may be confirmed in two ways. The specific gravity of the distillate of tar acids at 15.5° C. is determined and should be less than 1.0516 if phenol is absent. Any higher value certainly indicates phenol; a lower value may be due to *m*- and *p*-cresol mixed with *o*-cresol or phenol, or both.

The following test with bromine water reveals the presence of phenol in this distillate; 0.1 to 0.2 c.c. of the distillate is placed in a stoppered 100 c.c. cylinder with 10 to 15 c.c. of water and a few drops of strong hydrochloric acid. The mixture is well shaken and 80 c.c. of saturated aqueous bromine solution is added. In the presence of phenol (less than 5%) a voluminous, light, flocculent precipitate is formed. The presence of cresols does not interfere with this test. The cresols alone form oily or heavy granular precipitates which subside almost immediately.

The bromine precipitate may be advantageously examined under the microscope. The precipitate from pure phenol consists entirely of small, detached needles which are almost colourless by transmitted light, whilst that obtained from the cresols appears nodular and has a much deeper yellow colour under the same conditions. Higher magnification shows these nodules to be aggregates of very small needles.

The solidifying point of the phenol used for the determination must be re-determined from time to time because phenol absorbs traces of moisture readily and the solidifying point is lowered appreciably after a fresh bottle has been opened for some time. This, however, does not interfere with the use of the curves. The correction for the solidifying point of the phenol is added to or deducted from the observed solidifying point of a mixture according as the re-determined solidifying point is higher or lower than that of the phenol used in constructing the curves. The boiling points given in this description refer to pressures in the neighbourhood of 760 mm.

If the cresylic acid contains large amounts of naphthalene, neutral tar oils, or bases, a preliminary examination is made on a separate quantity to determine the proportion of tar acids. Any of the ordinary methods may be used for this purpose. After the proportion of tar acids has been ascertained such an amount of the sample is taken as will yield at least 100 c.c. of tar acids. These are separated by means of aqueous sodium hydroxide and treated in the manner described above.

THE ABSORPTION OF ATMOSPHERIC GASES BY WATER.

BY J. H. COSTE.

In 1803 Henry published his discovery that "under equal circumstances of temperature, water takes up, in all cases, the same volume of condensed gas as of gas under ordinary pressure. But, as the spaces occupied by every gas are inversely as the compressing force, it follows that water takes up of gas condensed by 1, 2, or more additional atmospheres, a quantity which ordinarily compressed would be equal to 2, 3, etc., the volume absorbed under the common pressure of the atmosphere."¹ Dalton, in the same year, working in close touch with Henry, extended this law, showing its application to gaseous mixtures. He wrote:—

"If a quantity of water free from air be agitated with a mixture of two or more gases (such as atmospheric air) the water will absorb portions of each gas the same as if they were presented to it separately in their proper density, *e.g.*, atmospheric air, consisting of 79 parts of azotic gas and 21 parts oxygenous gas per cent.

Water absorbs $\frac{1}{4}$ of $\frac{79}{100}$ azotic gas = 1.234
 $\frac{1}{4}$ of $\frac{21}{100}$ oxygen gas = 0.778."²

Very little attention appears to have been given to the actual absorption by water of the gases of the air, or of other gases, until, in 1855, Bunsen and his pupils investigated many gases, including air. Another aspect of the same question, however, received more attention, that is, the actual gaseous content of sea water. In 1836—7 from the French exploring ship "Bonite," nine samples of water were collected in the Indian, Pacific, and Atlantic Oceans, and submitted to analysis in the laboratory of the College of France. The results of these analyses were published by Fréay or Darondeau,³ but it is difficult to obtain much information from them. It is obvious that the oxygen was largely used up, but the proportions of nitrogen are rather extraordinary. In 1843 Morren investigated the gaseous content of the surface water near St. Malo at various seasons of the year. He found that sea water contained appreciably less oxygen and nitrogen than fresh water, and that the oxygen content was greatest and the carbon dioxide least in bright weather. Lewy repeated this work at Langune in 1846.⁴ Hayes⁵ in 1851 found that the oxygen was less at great depths than at the surface. In 1855 Pisani did some work on the ratio of oxygen to nitrogen at Brijak Déré. H.M.S. "Porcupine" was sent out in 1869 and several samples of water were collected with suitable precautions and boiled out. W. L. Carpenter, J. Hunter, and P. H. Carpenter successively undertook this work. Hunter published his results in an interesting paper,⁶ which provoked some discussion.⁷ Jacobson^{7a} did some work in the Baltic in 1871, and in the North Sea in 1872. Tornøe,⁸ Dittmar,⁹ Hamberg,¹⁰ and Pettersson,¹¹ from 1876 to 1889, carried out various pieces of useful work in connection with the Norwegian North Atlantic, "The Challenger," and Nordenskiöld's expeditions. The subject was also investigated by Winkler, Roscoe and Lunt, and Bohr from the more purely theoretical point of view from 1889 onwards. Many useful papers dealing rather with the public health point of view have appeared in this and other Journals, many by British workers. Attention will be called to these in due course.

I. The solubility of the gases of the air in water.—Bunsen did most of his work on the solubility of gases in his absorptiometer, agitating definite volumes of gas and water, and noting the diminution of volume of the gas due to absorption by the liquid, observing, of course, the temperature and pressure. This method is, in practice, only applicable to pure gases, since the volume of a mixed gas must be almost infinitely large relatively to

that of the water if the composition of the gas is not to be altered by selective absorption of its constituents. He therefore investigated the case of air and water by making a series of experiments on the absorption coefficient of nitrogen, and by boiling out water saturated with air at 0° C., at 13° C., and at 23° C.* From the data thus obtained, and his accurate knowledge of the composition of air, he was able to calculate the absorption coefficients of air and of oxygen. He concluded that "it is clear that the composition of the air dissolved in water at various temperatures is always constant. The mean composition is: oxygen, 31.91%; nitrogen, 65.09%."¹² Since his three experiments gave 31.91, 34.73, and 35.08% of oxygen respectively, the conclusion appeared to be justified. It was in fact shared by the later workers, Roscoe and Lunt, and Pettersson, and Söndén, who, however, like all subsequent workers, obtained rather less oxygen and more nitrogen than he did. This conclusion appears to be inaccurate, although the differences at various temperatures are not great.

Tornøe⁸ appears to have been the first to point out that the percentage of oxygen in the mixture of oxygen and nitrogen was a decreasing one—even within the range of Bunsen's three experiments. This was confirmed by Dittmar,⁹ Winkler,¹³ and Bohr and Bock.¹⁴ The values obtained for this ratio at varying temperatures by different workers are given in Table I.

TABLE I.

°C	Tornøe.		Dittmar.		Winkler.		
		Sea.	Dis-tilled.		1888.	1901.	1904.

25	—	33.62	33.6	33.7	—	33.82	
30	—	33.47	33.1	—	—	33.60	
40	—	—	—	—	—	—	

Roscoe and Lunt¹⁵ found from 10°—25° C. a mean percentage of oxygen 33.64, Pettersson and Söndén¹¹ for 0°—14° C. found 33.56, but their highest percentage, 33.88, was found at 0° and their lowest, 33.24, at 14°.

The following table (II.) gives a general survey of the scope and methods of the various workers on this subject. Without discussing the work at length, a few comments may be useful. Bunsen's work stands alone as that of a pioneer, and cannot be criticised like that of other workers. Tornøe worked with a boiling out apparatus (Jacobson's)^{7a} very much like Bunsen's; he was very careful about the saturation of his water, using both supersaturated and unsaturated water, which he brought into equilibrium with the air by shaking. Dittmar's work was extremely thorough and careful. He had the valuable help of Mr. Lennox in making his glass apparatus. Bohr, later with Bock, used two forms of absorptiometer and also a boiling out apparatus. They also used great care in saturating the water, and determined directly the coefficients of both oxygen and nitrogen. Hamberg¹⁰ did not investigate the oxygen content of water, but he made a series of experiments on salt water of different strength from 0 to 3.5% NaCl. Winkler^{13, 16} used his own elegant iodometric process for oxygen, a simple boiling out process, and later an absorptiometer of good design^{17, 18}. He seems finally to have preferred the values calculated from determinations of the oxygen in water (iodometric) and i

* The action of oxygen on mercury was a reason again attempts at direct determination of the absorption coefficient of oxygen.

TABLE II.

• Published in Copenhagen.

the air boiled out of water,¹⁹ thereby obtaining rather higher values for nitrogen than those calculated from the absorption coefficients of the two gases. His work and Bohr's cover a greater range of temperature than any other, and his values are probably the best of any. Roscoe and Lunt determined the volumes of the gases pumped out from water at four temperatures, 10°, 15°, 20°, and 25°, and extrapolated to 5° and 30°. The results agreed well with one another, but some of the details are not clear, and the work appears only as an appendix to a paper on Schützenberger's process. In the accompanying diagram (Fig. I, p. 848) Winkler's values for oxygen and nitrogen dissolved in distilled water¹⁹ between 0° and 30°C. and Dittmar's values for sea water, are given as continuous curves; the others are shown at the points where determinations were made. The values for sea water are much lower than those for fresh water. The ratios O:N appear to be the same as for fresh water, but the actual amounts are about 20% lower, varying appreciably with the salinity of the water. Hamburg¹⁰ investigated the effect of such variations on the nitrogen content, whilst Clowes and Biggs²⁰ determined, by Winkler's method, the oxygen content of several mixtures of salt and fresh water. As Hamburg's results are less accessible to members of this Society than are those of my colleagues I give them in Table III.

The solubility of nitrogen in water of varying salinity has also been investigated by Braun.⁵⁸ J.C. Philip⁷³ has discussed the general question of the influence of other solutes on the solubility of gases.

TABLE III.

Volumes of nitrogen at n.t.p. contained in salt water saturated with air at a dry pressure (Bar. 760 + t.a.v.) of 760 mm. (Hamburg).

°C	0% NaCl.	1% NaCl.	2% NaCl.	3% NaCl.	3.5% NaCl.
	c.c.	c.c.	c.c.	c.c.	c.c.
0°	19.14	17.71	16.45	15.34	14.85
5°	16.93	15.76	14.70	13.75	13.32
10°	15.14	14.16	13.26	12.44	12.06
15°	13.73	12.88	12.10	11.38	11.04
20°	12.63	11.87	11.17	10.54	10.25
25°	11.81	11.09	10.45	9.88	9.62

The curves (Fig. II.) show that Hamburg's smoothed values for nitrogen agree fairly with Clowes' and Biggs' actual values for oxygen, also that the falling off of nitrogen with increasing salinity is greater at lower temperatures.

The content of oxygen and nitrogen in sea water itself—not, by the way, a very definite

liquid—is shown in the curve and points (Fig. I). The principal effect of the salts dissolved in sea water is to decrease the amount of dissolved gases. It will be seen that I take Dittmar's "Challenger" figures as the standard. This I consider to be fully justified.*

So far we have only considered the two predominant gases of air, but, of course, air also contains carbon dioxide and argon in easily determinable quantities, besides traces of other gases. The cases of the two above-mentioned gases are worthy of consideration.

Carbon dioxide is very soluble in water; the following values show the amounts of the dry gas dissolved at a (dry) pressure of 760 mm. by 1 c.c. of water at varying temperatures (Bohr and Bock).¹⁴

TABLE IV.

	0°	5°	10°	15°	20°	25°	30°
c.c. CO ₂	1.713	1.424	1.194	1.019	0.878	0.759	0.665

One litre of water would therefore dissolve from air containing 0.03% CO₂ at:—

TABLE V.

	0°	5°	10°	15°	20°	25°	30°
c.c. CO ₂	0.514	0.427	0.358	0.306	0.264	0.228	0.199

but natural water usually contains carbonates of the alkali or alkaline-earth metals in solution as bicarbonates which yield part of their carbon dioxide on boiling, so that the case in nature is not quite simple. In addition, carbon dioxide is a product of the decay of organic matter in water. Argon is present in air to the extent of about 1%. Rayleigh and Ramsay said of it:²¹ "The gas seemed to rebel against the law of addition. It was thought that the cause lay probably in the solubility of the gas in water, a suspicion since confirmed." The absorption coefficient of this gas in water has been determined by Winkler, Estreicher,²³ and Andropoff.²⁴ Winkler's values are given below:—

TABLE VI.

1 c.c. water dissolves at	0°	10°	20°	30°	40°
c.c. argon	0.053	0.042	0.035	0.030	0.027

Estreicher's values are about 9% higher than Winkler's. Since air contains about 1% of argon, water in equilibrium with it should contain, per litre, the following amounts of argon:—

TABLE VII.

at	0°	10°	20°	30°	40°
	0.53	0.42	0.35	0.30	0.27 c.c. A.

The determination of the proportion of argon in the gases extracted from water might, in

*Dittmar's sea water "was prepared synthetically on a large scale from pure salts and distilled water, so as to represent about an average 'Challenger' water," probably containing 3.52% solids and 1.95% Cl.

certain cases, be of value in deciding the origin of the nitrogen, whether atmospheric or "chemical." Such a determination appears not to present insuperable difficulties, but would require very great care.

A curious fact about argon was observed by Kistiakowski.²² It diffuses through caoutchouc a hundred times as rapidly as carbon dioxide. This rapid diffusion may in part account for some of the discrepancies in the amounts of "nitrogen" extracted from water by different workers.

The other gases of the atmosphere are present in such small amounts that their presence in water would not be of great significance.

A consideration of the results graphically indicated on Fig. 1. which have been calculated, where necessary, from absorption coefficients or other expressions to a basis of 760 millimetres actual barometric reading, shows that, on the whole, the agreement is good, especially having regard to the variety of methods used by various workers. The greater discrepancy observable in the sea water figures may reasonably be attributed to varying salinity. Tornøe's results are lower than Dittmar's. The North Atlantic, which was the ocean specially examined by Tornøe, yielded Dittmar the greatest proportion of salts found by him in "The Challenger" water, viz., 37.37 parts per

FIG. 1.

1000, whilst the lowest (33.01) was found in the Indian Ocean. Dittmar used a water of medium salinity for his experiments. Braun²³, whose values are not shown, as they are not comparable with the others, worked with pure nitrogen obtained by the interaction of sodium nitrite and ammonium sulphate. His absorption coefficients are given below as compared with those of other workers. They refer to the volume of pure nitrogen absorbed by 1 c.c. of water when the dry pressure of the pure gas (not air) is 760 mm.

TABLE VIII.
Absorption coefficients of nitrogen.

Temp. C°.	Winkler.	Bohr & Bock.	Braun.	Dittmar.

10	0.01915	0.01956	0.02003	0.01943
15	0.01737	0.01786	0.01789	0.01765
20	0.01598	0.01639	0.01621	0.01619
25	0.01494	0.01504	—	

It is probable that the principal cause of discrepancies is the difficulty of obtaining satisfactory

indicate. The use of inverted commas—"nitrogen"—indicates, in this paper, that the gas under consideration is that mixture which before 1895 we all called nitrogen.

The CO₂ figures in Fig. 1. are based on 0.03 % CO₂ in the air. It seems to be agreed that the older figure 0.04 was too high.

II. Rate of absorption of atmospheric gases by water.—The amount of the two principal gases of air which can be dissolved by water of varying salinity has been shown to be on the whole well ascertained. Another point which is of importance is the rate at which de-aerated water will absorb those gases. Dittmar says (*loc. cit.*): "Supposing a certain portion of the ocean were separated from the rest, and after having somehow been deprived of its gaseous contents, exposed to the air at a constant temperature of t°. The three gases would stream into the water at a steadily diminishing rate until absorptiometric equilibrium was established, i.e., a point reached when, for instance, the number of molecules of oxygen dissolved in a given small time would be exactly compensated by the same number of previously dissolved oxygen molecules returned to the atmosphere." This was written several years before reactions of this class had been investigated,

FIG. II.

equilibrium between water and the air or other gas above it. If the bubbling method of saturation is used, one is faced by the fact that the water is aerated at a pressure rather above atmospheric, owing to the height of the water column through which the bubbles have to pass. Winkler, who used this method for his direct experiments with air, took the pressure of saturation as equal to that of the atmosphere + half the water pressure; he points out the desirability of using shallow vessels for the water. Shaking appears to be a good method of saturation, but temperature variations may occur between the time of shaking and determination of gaseous content. The gaseous exchanges, as the point of saturation is reached from either side, are very slow.

The presence of the relatively soluble gas argon in air has no doubt had some effect on the nitrogen figures, although Braun's figures on chemical nitrogen do not differ from the others in the sense which the inferior solubility of this gas would

and is a distinct adumbration of Bohr's work on invasion and evasion coefficients.²⁵ As a matter of fact, many physical phenomena suggest such a course of events.

The first actual investigation of the rate of interaction between a gas and a liquid appears to have been undertaken by Knox,²⁶ who determined the rate of removal of carbon dioxide from water by means of a current of air. He concluded that "Der Verlauf der Entsättigung ist ein genähert logarithmischer." Perman²⁷ came to a similar conclusion in respect of carbon dioxide and some other gases, as also did Meyer²⁸ and Roth.²⁹ Duncan and Hoppe Seyler³⁰ investigated the absorption of the gases of air by water in connection with their classical work on fish life, but although their results follow the course indicated by Dittmar, they did not attempt to deduce any law regulating the rate of absorption. Dibdin³¹ made a series of experiments to clear up this point and drew a curve. He appears to have been the first to

attempt to estimate the rate of absorption of oxygen from the percentage saturation. His curve is not throughout its whole length exactly of the form which could be expressed by an exponential formula, but it fairly approximates to such a form. The work was never put directly before the scientific public, and has therefore received little attention. Roth (*loc. cit.*) quotes a paper by Raoult,³² in the course of which he found it necessary to determine the rate of absorption of air by water in order to apply a small correction to some of his work on molecular weight determinations. Roth shows that the equation—

$$(i) K = \frac{1}{t} \log_e \frac{c}{c-x}, \text{ which may be written}$$

$$(ii.) \frac{c-x}{c} = e^{-kt}, \text{ whence } \frac{dx}{dt} = k(c-x) \quad (iii)$$

where c = the saturation concentration, x the concentration at any time, t , and k is a constant, will express Raoult's results.

A large amount of work was done on this point by the Metropolitan Sewerage Commission of New York³³ in 1914, but here again there was no attempt to obtain a mathematical expression for the rate of re-aeration, and the actual results do not follow quite the course which an exponential formula would require. They will not stand the test of plotting logs, and time to get a straight line.

The absorption of a gas by a liquid is a heterogeneous reaction, very similar to the solution of a solid by a liquid. There is a definite boundary between the phases which is on the whole more easily defined and regulated than in the case of solids and liquids. Now this latter case has been investigated by Noyes and Whitney,³¹ and later by Brunner³⁵ under the guidance of Nernst.³⁶ These workers found that the velocity of such reaction could be expressed by the equation—

$$\frac{dx}{dt} = C(S-x) \quad (iv.).$$

x being the concentration of the solution at time t and S that of the saturated solution, C being a constant. This equation is identical with (iii.). Both groups of workers came to the conclusion that what they were measuring was really the rate of diffusion of the saturated solution of the solute in the solvent or in the bulk of the solution, there being no doubt in their minds that the solution at the boundary of the two phases, solid and liquid, was saturated, and that with rapid stirring the fall of concentration from saturation to that of the main bulk of the solution occurred in a layer of extreme thinness.

Brunner estimated this layer as varying in his experiments from 0.018 to 0.052 mm. Its thickness appeared to be proportional to the $\frac{2}{3}$ power of the rate of stirring. The above equation (iv.) is in agreement with the rate of diffusion as based on Fick's law of diffusion.

The difference—not very great—which is to be observed in the form of a curve calculated from, say, the half saturation point, by means of the exponential formula (ii.) from the actual curve, showing the rate of absorption of, say, oxygen (most of the experiments were conducted more from the point of view of public health than from that of physical chemistry) are, in my opinion, easily explained by the fact that still water only was experimented with. Hence, owing to slowness of diffusion downward, the aeration was much less rapid and regular than would have been the case if the liquid had been properly mixed. I have found that water stirred without breaking the surface absorbs air much more rapidly than still water under otherwise exactly similar conditions. I am aware that Adeney and Letts³⁷ have expressed very different views as to the

absorption of gases by water, based on Adeney's very careful, well designed, and interesting experiments. They say: "It is generally believed that the atmospheric gases as they are dissolved by de-aerated water, remain more or less concentrated in the layer of water exposed to the air, and are only slowly circulated through the water by thermal currents and diffusion. The results of the experiments show that this belief is not well founded. They afford strong evidence to the contrary, since it is evident from them that the gases as they are dissolved at the surface, pass through sea water with comparative rapidity. They also show that the slow rate of re-aeration is due to some retardation of the process of solution at the surface of the liquid exposed to the air."* The statement italicised seems to me to be directly contrary to the facts shown by practically all Adeney's experiments. In, I think, every case where he examined samples taken from different depths of a mass of water exposed at its surface to the air, the dissolved gas was less in amount in the deeper layers; that is, however fast the diffusion may have been, it could not keep pace with the rate of aeration at the surface. The experiments (*e.g.*, Nos. 8 and 9) with broken surfaces show the same thing; he obtained a high concentration—practically saturation—in the layer through which air was bubbled, but owing to the relative slowness of diffusion or the interesting phenomenon of "streaming" which he examined, there was a progressive falling off in the lower layers. I have prepared a diagram (Fig. III.) showing this for some of his experiments (Nos. 1, 8, and 9). Without discussing the matter

FIG. III.

at great length, one may say that Adeney's work shows conclusively that pure diffusion in still water, which appears to conform to Fick's law, is *very slow*, that some other phenomenon which he calls "streaming" undoubtedly comes into play when ordinary air is over ordinary sea water, and that in his words "the aeration of all aerated

* My italics.—J. H. C.

water, when protected from circulation of the surface layers* to the bottom by thermal currents requires long periods of time, extending to more than 30 days, for completion. But it is unlikely that conditions so unfavourable to re-aeration exist in nature." As Adeney did not carry out a series of experiments on the rate of absorption, he does not seem to have realised that the rate of absorption is a decreasing one; in fact, it is assumed in the report from which quotations have been made to be constant throughout an experiment lasting as long as 48 hours.

I consider it to be certain that, given motion of the water such as will occur in a tidal or fairly rapid river, the rate of absorption of gases from the air is directly proportional to the saturation difference, as Brunner calls it. A more convenient expression for this case is "co-aeration," i.e., the difference between 100 and the percentage saturation. In other words, the difference between 100 and the percentage saturation with, say, oxygen, is a direct measure of the rate at which the water is, at the time of experiment, absorbing oxygen as compared with the limiting rate.

NOTE.—I have been able to confirm Adeney's remarkable observation that gases dissolved in water can pass downwards with very much greater rapidity than they can travel horizontally or upwards, showing the great slowness of pure diffusion as compared with "streaming" (cf. also Hufner³⁸).

The experiments of Schleiermacher³⁹ and Marek⁴⁰ on the difference of density of water saturated with air and air-free water show such minute and uncertain differences as not to confirm Hufner's explanation of the phenomenon, which appears to be of the nature suggested by Adeney.

III. The gases in solution in natural water.—The proportion of atmospheric gases which water, either fresh or salt, can absorb, and the rate at which these gases are absorbed, has been defined. The question now arises what actually are the amounts of gas found in natural waters?

The simplest case would appear to be that of rain water, which one would expect to be in complete equilibrium with the air through which it had passed. Some old analyses from various sources are given below.

TABLE IX.
Gases dissolved in rain water.

	Baumert. 41	Pelagot. 41	McLeod. ⁴² (mean of 2)		Frankland 43	
	°	%	c.c.	%	c.c.	%
Oxygen ..	33.7	31.2	0.673	30.7	0.637	30.7
" Nitrogen "	64.5	66.4	1.382	63.1	1.308	63.1
Carbon-dioxide	1.8	2.4	0.135	6.2	0.128	6.2
	100.0	100.0	2.190 in 100 c.c.	100.0	2.073 in 100 c.c.	100.0

It will be noted that whereas the two former analyses contain proportions of CO₂ which correspond fairly with air containing 0.03% or thereabouts, the other two analyses contain much more CO₂, corresponding to about 0.1%. McLeod's rain water was collected at the old College of Chemistry on July 28th, 1869, between 10 a.m. and noon. The ratio of oxygen and "nitrogen" is in each case very close to the normal. It may be remarked that Rayleigh and Ramsay found the "nitrogen" extracted from rain water to contain about twice as much argon as air does.

It may be said generally that the water of rivers and seas which are uncontaminated with matters which absorb oxygen contains proportions of oxygen and nitrogen which approximate closely to the saturation amounts calculated for

* My italics.—J. H. C.

their temperature and saline contents. Some examples from various sources will illustrate this (Table X.).

TABLE X.
Gases from 100 c.c. water.

	Cumberland mountain stream. 43	Thames. 43	Jena water supply. 44	R. Mälar. 41
Oxygen	0.726	0.588	0.77	0.91
" Nitrogen "	1.424	1.325	1.76	1.87
Carbon-dioxide ..	0.281	4.021	2.47	—
Oxygen × 100	33.8	30.4	30.3	32.7
Oxygen + nitrogen				

Since the temperatures are not available, one can only remark that the actual amounts are in the neighbourhood of saturation at ordinary temperatures, whilst the ratios show only very slight divergencies—all on the low side—from the normal proportion of oxygen. The proportions of carbon dioxide are more variable. This is easily accounted for by the presence in most waters of bicarbonates as well as free CO₂.

Sea and river waters appear to differ but little in gaseous contents from surface to great depths. The following table from Tornoe illustrates this for nitrogen. The oxygen expressed as a percentage of oxygen plus nitrogen varied from 35.31 to 32.58.

TABLE XI.

Proportion of nitrogen in water of North Atlantic at various depths (Tornoe).

Depth, fathoms.	Temperature, ° C.	Nitrogen	
		Found.	Calculated.
0	6.4	13.07	12.93
0—100	2.7	13.98	13.78
100—300	1.0	14.14	14.17
300—600	− 0.68	14.54	14.54
600—1000	− 0.8	14.04	14.58
1000—1760	− 1.4	14.36	14.72

I have found the oxygen content of rivers to vary very slightly at different depths, even when appreciably different from the saturation figure. I consider the nitrogen much less likely to vary.

The gaseous content of water is likely to be divergent from the saturation figure, either above or below it, if the temperature of the water has varied rapidly. The phenomenon of super-saturation—at any rate with oxygen—is by no means a rare one. It is sometimes to be attributed to the above cause, but, I think, more often to its excretion from vegetation as a residual product of photosynthesis. Last summer I kept a small aquarium (19 litres) under observation; the oxygen content of the water always increased from morning to evening, and frequently was well above saturation. I have found natural water to contain as much as 180% of its saturation figure of oxygen with a normal nitrogen. The oxygen was reduced to near saturation by shaking. (See also C. A. Seyler⁴⁵.)

IV. The methods and apparatus employed for the determination of gases in water.—The gases dissolved in water can be extracted either (A) by boiling the water and evolving the gases with the steam (a consideration of the rapid decrease of the solubility with rise of temperature will show that this is an efficient method); (B) by pumping out and boiling at reduced pressure; or (C) by driving out with a current of some other gas. There are also several chemical methods for oxygen and for carbon dioxide.

(A.) Bunsen described⁴⁶ and used a boiling out apparatus with a collecting tube connected to it, which could be evacuated by boiling a small quantity of water contained in it and then sealing the upper end. Jacobson⁷⁴ modified and improved this. His apparatus was used by Buchanan (on "The Challenger") and others. Winkler⁴⁷ collected the gas in a rather similar upper tube, previously evacuated and sealed top and bottom, breaking the lower seal within a rubber tube connected to the boiling flask. Pettersson described, and he and Sonden used,¹¹ a very good boiling out and measuring apparatus combined.

(B.) McLeod⁴² in 1869 described a pumping out apparatus with a Sprengel pump. Dibdin⁴⁸ modified and simplified this. His apparatus was used for thousands of samples in 1893-4, and is very good. Roscoe and Lunt¹⁵ used a pumping out apparatus, as also did Dittmar,⁹ and Bohr and Bock,¹⁴ and Hoppe Seyler,⁷⁵ and Trueman.⁴⁹

(C.) Winkler⁵⁰ described a most convenient and simple apparatus for the determination of oxygen and nitrogen by driving out with CO_2 generated in the water by the action of hydrochloric acid on calcite, and subsequently analysing the gas (which is collected over 20% NaOH solution) over water. It gives good results, and can easily be used on board ship. It is on the whole the most practical apparatus, for general use, of any which I have seen described. Other apparatus are referred to in the bibliography. McLeod recognised the great difficulty in expelling the last traces of CO_2 from bicarbonate. Pettersson, and later Adeney,³⁷ who himself has described a good apparatus, found that the addition of sulphuric acid was necessary to complete the process. Pettersson called attention to the loss of oxygen when sulphuric acid was used in contact with mercury.

Of chemical processes for the determination of oxygen, Mohr's ferrous hydroxide process⁵¹, and Schützenberger's hyposulphite method, and Thresh's iodometric and nitrite process have all been found useful, but notwithstanding the improvements by Albert Levy, and Letts and Blake, by Roscoe and Lunt¹⁵, Adams,⁵⁶ and others, I heartily confirm the conclusion of Kisch,⁵⁷ that Winkler's manganous iodometric process is the best of all these chemical processes. Water analysts owe a great debt of gratitude to this worker for his many contributions to this branch of analytical chemistry.

Carbon dioxide can be titrated in the water by acidimetric processes or evolved by hydrogen.

V. *The significance of the gases dissolved in natural waters.*—Water, which is exposed freely to the air, should and does contain the proportion of gases of the air which are proper to its temperature and saline content, provided these have not changed recently. If, therefore, the examination of the water shows a deficiency of one or other of these gases there must be some abnormal cause at work.

Both argon and nitrogen are chemically rather inert. They are seldom considered apart, and a deficiency or excess of their sum, as compared with the saturation figure, is hardly likely to be greater in amount than could be accounted for by recent temperature changes. Greater differences could only be due to the influx of underground water. The Royal Commission on Pollution of Rivers, 1868,⁴³ of which the late Sir E. Frankland was a member, said: "It was at one time supposed that the proportion of oxygen in these gases was an important item in the history of the water, and it was believed to indicate if small the presence of putrescent organic matter; but the subsequent discovery that deep well waters (in which putrescent organic matter is certainly not present) contain little or no dissolved oxygen, deprived this analytical fact of much of its importance."

They gave the following figures:—

<i>Deep chalk well water.</i>	
" Nitrogen "	1.944
Oxygen	0.028
Carbon dioxide	5.520

7.492 c.c. in 100 c.c. water.

It seems to be rather straining a point to quote the case of a water which must have travelled a long way underground, and which may have had many opportunities of parting with its dissolved oxygen, as a proof of the inutility of a determination, the results of which should obviously be considered in relation to the contact of water with the air. It might be urged with reason that the large CO_2 content of the gases indicated a bad past history, since this gas, even although associated with lime, must have been, at least in part, organic in origin.

All the ascertained facts show that if water is found to contain very much less oxygen than the saturation figure for its temperature, a strong presumption is raised that there is matter in that water which requires a more or less considerable proportion of oxygen for its oxidation. Since, however, the water may have recently fallen in temperature, the point, in some cases, can only definitely be settled by determining the "nitrogen," the constituent which, so far as is known, is not taken up chemically by anything in the water. If the nitrogen is approximately twice the volume of the oxygen the deficient saturation must be due to the temperature having fallen at a higher rate than re-absorption can make up. Having regard to the slowness of absorption as saturation is neared, this is probably often the case. If the water under examination has not undergone any recent change of temperature, it may be assumed that a deficiency of oxygen indicates an appreciable demand for oxidation on the part of organic matter in the water. Provided the water is in fairly rapid motion, samples taken at different depths are not likely to differ much in oxygen content. In this case the percentage aeration subtracted from 100—the co-aeration—will give a direct measure of the extent to which the limit of absorption of the water, under its conditions of depth, movement, etc., is reached.

It appears that slow non-tidal streams will give rise to unpleasant symptoms at much higher aeration than deep streams with strong tidal currents. This is probably due to a variety of causes such as slowness of downward diffusion in the less rapid streams; the accumulation of undisturbed mud which, in fermenting, gives off gases which have little opportunity of being absorbed in their passage through shallow and still water. I think that matters which are dissolved in water, unless in simply enormous amounts, will be unlikely to give rise to offensive conditions in moving water, owing to the surface concentration of dissolved gases. It is probably only when gaseous products of putrefactive action reach such a tension as to disturb the concentration of oxygen at the surface that a water becomes offensive.

The proportion of carbon dioxide in water would doubtless be a valuable indication if either air did not contain carbon dioxide or water did not pass through or over rocks containing lime. As it is, the case is far too complicated for one to be able to make much of it.

The examination of the gases dissolved in water is complementary to the determination of the absorption of oxygen from permanganate or from aerated water which is not in contact with the air. The two latter determinations give an idea of how much oxidisable matter is present; the former tells us, not how much there is, but at what relative rate it is being oxidised, not *in vitro*, but *in fluvio*.

SUMMARY.

I. The conditions of equilibrium between water and the constituents of the air above it are well defined as depending on the actual solubility in water of the gases, the temperature of the water, and the atmospheric pressure. (The effect of the composition of the air is constant.)

II. The rate of approach to a state of equilibrium in either direction (*i.e.*, from supersaturation or from partial saturation) follows the normal course of a heterogeneous reaction, that is, it is proportional to the divergence from saturation.

III. Natural water in free contact with air, and not containing substances which will react chemically with the gases of the air, contains those gases in the same proportions and amounts as pure water, except in so far as the amounts, but not the proportions, are affected by other matters in solution (*e.g.*, NaCl).

IV. Convenient and trustworthy methods for the determination of the gases in water are available both for laboratory and field use.

V. The examination of the gases dissolved in water affords one of the most useful means of determining the probable behaviour *in loco* of the water.

Yorkshire Section.

Meeting held at Queen's Hotel, Leeds, on Monday, April 3rd, 1917.

PROF. J. W. COBB IN THE CHAIR.

A NOTE ON BOILER CORROSION.

BY BASIL G. McLELLAN.

This paper deals with a case of boiler corrosion which I think may be typical of many others, and with an attempt to discover the cause of this corrosion.

A range of Lancashire boilers were fed prior to 1910 with town water with a total hardness of 17 to 23 parts per 100,000, of which 13 to 17 was temporary and the remainder permanent. A certain amount of oil had access to the feed water from waste steam, etc. Under these conditions a thin layer of hard scale accumulated in the boilers and this had to be chipped off periodically. There was no corrosion. The source of the feed water was changed, and well water, having 71 parts per 100,000 total hardness, softened down by lime and soda treatment to 7 or 8 parts, was used. This water contained an excess of chemicals just sufficient to reduce the hardness to zero; precautions were also taken to eliminate all traces of oil from the feed water. The result was freedom from corrosion and from scale in the boilers, with a moderately soft scale in the pre-heaters and economisers. To eliminate this scale, it was decided to reduce the hardness by using a greater excess of chemicals. This was done, and the softener was run for three weeks, producing a water with a hardness of 3 to 4 parts per 100,000 with an excess of chemicals equal to 11 or 12 parts per 100,000. This naturally brought about an accumulation of alkalis in the boiler. The effect of this alteration, which was observed the next time the boilers were opened, was a reduction of scale in the pre-heaters and economisers, no scale in the boilers, and the first appearance of corrosion there in the form of pitting. Even though the softening conditions were readjusted so as to eliminate the excess of alkali, the effect was similar to that formerly observed, but corrosion continued in the boilers.

This corrosion was observed at every inspection for several years. Sometimes it had gone on only to a moderate extent, and sometimes fairly rapidly. It was usually found on the furnace tubes and on the shell near the tubes, and later it was found in the lower part of the upper drums of water-tube boilers which had been installed.

This corrosion was due to oxidation, and I am of the opinion that the period of strong causticity removed from the boiler shell a thin layer of oil residue which for years had acted as a protective coating; the surface of the plates was thus rendered clean, active, and open to attack.

The opinions of experts were evenly balanced as to the cause, and these were:—

1. Oxidation by dissolved oxygen in the feed water.

2. Electrolytic action.

Remedial measures were proposed, or suggested themselves to us, for overcoming either of these corrosive influences, but it was necessary to determine which was causing the trouble.

At that time I was of the opinion that dissolved oxygen was not the cause of the corrosion, and that opinion was based very largely on the work of Professor Cobb (see this J., 1914, 403). If I interpret his results aright, corrosion by dissolved oxygen would take place near where the air was first liberated from solution in the water, namely, in the pre-heater tubes, and would certainly not extend beyond the batteries of economisers, where ample provision is made for blowing off the air which collects in them.

It is obviously difficult to devise experiments on a plant scale to decide a point like this, so an eliminating experiment on a laboratory scale was suggested, namely, to remove all dissolved oxygen and try whether corrosion took place in its absence. The experiment was carried out as follows:—

A number of similar bars of metal were cut from the same piece of boiler plate; these were machined up and polished. Two of them were suspended by means of iron wires in a bell jar; the wires passed through a rubber stopper, through which a three-way stoppered tube passed. The electrolytes used were placed in a large evaporating basin and

boiled until free from dissolved oxygen, tests being made (by Winkler's method) from time to time as boiling proceeded. The bell jar was then supported over the boiling liquid and filled with hydrogen through the stoppered tube. It was then lowered so as to be sealed by the electrolyte and hydrogen was passed in until all the oxygen was removed. The bell jar was then lowered, allowing hydrogen to escape, until about one half of each electrode was immersed. In a few moments the boiling was stopped, and air was excluded from the surface of the electrolyte outside the bell jar by covering it with a layer of mineral oil. During cooling the level inside and outside the bell jar was kept constant by adjusting the volume of hydrogen gas inside. The terminals were connected up to a millivolt meter, by means of which the difference of potential could be noted. It was thus possible to operate in absence of free oxygen.

The trials lasted for some days. The electrolyte was heated during several days, but the greater part of the time it was cold.

Trials were made with softened water, with boiler water which had become concentrated, and with distilled water.

Softened water. The technical analysis of this was as follows (in parts per 100,000 expressed as CaCO_3):—Hardness 8.7; alkalinity, to methyl orange 12.7, to phenolphthalein 9.7; (O11) alkalinity after removing carbonates 3.6. The water still contained 0.32 c.c. of oxygen per litre. The potential difference between the two electrodes varied up to 18 millivolts, first one electrode and then the other being at the higher potential; slight vibration of either was sufficient to alter its polarity, tending to make it electro-negative.

The trial lasted eight days; a considerable amount of rust settled in the basin, and the bars showed distinct signs of corrosion.

The electrolyte, at the end of the trial, contained 3.0 c.c. of oxygen per litre, the increase having been produced electrolytically.

Concentrated boiler water. This was a very concentrated liquor, resulting from under-softened water. The following figures show its composition:

Parts per 100,000 as CaCO_3 .			
Total alkalinity	212.6	Total hardness	35.5
Chlorides	505.7	Lime hardness	23.3
Sulphates	1390.3	Magnesia hardness	12.2
		Alkalis (diff.)	2233.1
Total acids	1908.6	Total bases	2268.6

The water was entirely free from dissolved oxygen. The potential difference was greater on the average than with the softened water.

The trial lasted 26 days, and the corrosion was very marked. At the end of the trial the electrolyte contained 0.9 c.c. of dissolved oxygen.

Distilled water. This trial was run to ascertain the effect of a very soft water. The water contained 0.28 c.c. of oxygen per litre. The potential difference throughout the run of 15 days was small, not exceeding 5 millivolts. The plates indicated some corrosion, which was confirmed by the deposit of rust in the basin. At the end of the trial the electrolyte contained 2.6 c.c. of oxygen per litre.

The conclusion to be drawn from these tests is that even the absence of dissolved oxygen is no guarantee that corrosion of this order will not take place. That the corrosion referred to in the boilers was caused solely by electrolytic action is not definitely proved, but the evidence is fairly strong.

Some years ago Cumberland devised an electrical apparatus for overcoming electrolytic

corrosion. Insulated iron rods are inserted into the boiler, heater, or whatever piece of plant is to be protected. Current, generated externally, sufficient to overcome any local potential differences is passed through the system so as to make these insulated rods the anodes. These corrode away, and are renewed from time to time. The electro-negative surfaces are kept free from scale and corrosion, and in cases where this plant has been installed in scaly boilers, the old scale has been removed, possibly by the formation of hydrogen below the scale.

The process has, I understand, been extensively installed on large ocean liners and also in factories. I have no direct experience of the process, but it seems to me to be sound. A reversal of current would be disastrous.

It is sometimes recommended to coat the inside of boilers with a protective paint as a cure for corrosion. Graphite in a volatile carrier is frequently used. If the corrosion is due solely to dissolved oxygen, this may be efficient, but unless the coating is absolutely perfect—which it never can be in practice—it is difficult to see how it can do otherwise than aid corrosion, graphite being electro-negative to iron.

Finally, we will look for a moment into certain conditions which have been observed to aid or retard boiler corrosion. It is frequently stated that small quantities of caustic soda in feed waters have little effect on the corrosive power, while similar quantities of sodium carbonate stimulate corrosion. This may be regarded as a rough-and-ready statement, but it is the experience of those who have to handle boilers. If we examine these statements in the light of the so-called and commonly accepted " CO_2 -theory" and from the point of view of electrolytic action, some light may be shed on them.

The " CO_2 -theory" is expressed as two equations:—

and shows the mode of action of water containing oxygen and CO_2 on iron. At boiler temperatures the latter equation might be:—

Now I think it is quite conceivable that an action of this kind can take place in a feed water which is devoid of free oxygen and carbon dioxide if it contains an excess of sodium carbonate. At the high temperatures in the boiler the sodium carbonate is partly dissociated and carbon dioxide is set free to form ferrous carbonate as in the first part of the CO_2 -theory. We have now to consider two electrodes, one of clean iron and the other of ferrous carbonate. I have no evidence to show which of these is electro-positive and which electro-negative, but there is almost certainly a considerable potential difference which will result in corrosion.

If there is sufficient excess of sodium hydroxide in the feed water, the dissociation will not be effective, and corrosion of this kind will not take place.

DISCUSSION.

The CHAIRMAN said that dissolved oxygen did cause corrosion and was often the principal cause. Corrosion by dissolved oxygen would show itself at the point where the water first came to be heated in contact with the iron plates. In plants where an economiser was used this corrosion would most likely be found in that portion of the plant. If there were no corrosion at that point, then dissolved oxygen as a cause fell out, but oxygen arising from chemical actions in the boiler was likely to play its part. Mr. McLellan was undoubtedly right in saying that corrosion was often electrolytic. He

(Prof. Cobb) had made experiments with regard to electrolytic corrosion, and his results agreed with those of Mr. McLellan. Local circuits were established between the pure iron and numberless particles of contained impurities. According to his experiments, it was nearly always the iron that passed into solution, while the impurities—silicates, phosphides, etc.—remained unattacked.

Mr. W. McD. MACKEY asked if the boiler was of steel. He also said that Mr. McLellan had not said much about the remedies tried. He asked if tannin had been tried.

Mr. F. W. RICHARDSON asked if Mr. McLellan's remarks applied to the action of soft waters on conduits: the conduits were not always full of water. He did not think it wise to allow any accumulation of caustic soda, as this was liable to produce priming. Tannic acid, together with the excess of caustic soda, gave an oxygen-absorbing liquid, and this would most likely put an end to corrosion by dissolved oxygen.

Mr. Lowson asked if the layer of oil as used in the experiment was sufficient to keep the oxygen of the air away from the electrolyte. He had found in certain cases that oxygen appeared to pass through paraffin with surprising speed.

Mr. J. MILLER said that Lyons, of the United States Navy, had found that boiler corrosion increased with the alkali up to a certain point, when the corrosion stopped. His idea was to put in an excess of alkali and so eliminate all corrosion. In Mr. Miller's experience, oxygen passed through a layer of xylol very quickly, and he therefore doubted whether the electrolyte was free from dissolved oxygen at any time throughout the experiment.

In reply Mr. McLELLAN said that remedies of the type mentioned by Mr. Richardson might be effective for preventing corrosion by dissolved oxygen. The experiments described pointed to electrolytic corrosion, and other means must be adopted to prevent this. No remedial measures had been tried because for some unknown reason corrosion had now practically ceased. Many analyses of the hard and softened waters had been made; they contained no nitrates, and would be described as non-corrosive. The corrosion of conduit pipes was probably ordinary rusting caused by dissolved oxygen. When making the experiments he had been under the impression that the oil layer was a safeguard against atmospheric oxygen, and the point mentioned by Mr. Lowson and Mr. Miller was new to him. However, the fact that the millivoltmeter needle was immediately deflected the moment the electrodes were immersed in the liquor showed that, at any rate, the conclusions were correct.

ADDENDUM.

To make this quite clear, and to eliminate the use of hydrogen which might be regarded as metal, the experiment was repeated as follows (the diagram, p. 856, shows the apparatus at the commencement of the experiment). The electrolyte was placed in flask A and also in the beaker, B. A current of nitrogen was passed through the whole apparatus by way of the three-way tap until all the air was driven out. (The beaker, C, is useful for giving an idea of the speed at which nitrogen is passing.) The electrolyte in flask A was vigorously boiled, and the steam evolved caused the water in beaker B to boil. After boiling half an hour, the water in beaker B was tested and found to be absolutely free from oxygen. Clip D was then closed and the heating stopped; some water was thus allowed to run back from B into A, the quantity being controlled by the clip, E, which was finally closed. By applying suction to the tube in beaker C the electrolyte in A was drawn over into flask F until it reached the lower end of the tube, G. Pressures were then

adjusted by admitting nitrogen as before through the flasks, G, A, and beaker, B, opening the clips when the pressures were balanced.

One trial lasting 16 days was made with concentrated boiler water having the following composition.

Parts per 100,000 (as CaCO_3).

Total alkalinity	21.1	Total hardness	40.6
Chlorides	152.8	Lime hardness	26.9
Sulphates	1187.5	Magnesia hardness	13.7
		Alkalis (by diff.) ..	1371.3
Total acids	1361.4	Total bases	1411.9

As before the electrolyte was heated during several days. The potential differences observed were of a similar nature to those in the former experiments. Very considerable corrosion took place on both electrodes, which substantiated the conclusions arrived at in the paper.

Communication.

ESTIMATION OF NITROTOLUENES.

By E. DE W. S. COLVER AND E. B. R. PRIDEAUX.

In reply to Dr. Knecht's comments on our paper published in this Journal for 1917, page 480, we wish in the first place to disclaim any intention of undervaluing titanium chloride titrations as described in his book, "New Reduction Methods in Volumetric Analysis."

Our main object, as stated in the paper, was to investigate and define the limits of accuracy of the stannous chloride reduction method, to which perhaps full justice has not been done in previous descriptions. Having furnished sufficient experimental material for this object we do not take it upon ourselves to pass any general judgment on the relative applicability of the two methods.

Attention was, however, called incidentally to the necessity for sulphonation or the use of alcohol in the titanium reduction. ("New Reduction Methods," pp. 26-28.) With stannous chloride reduction sulphonation is not necessary in the case of mononitrotoluenes, nor is there any need to dissolve dinitrotoluenes in alcohol. In the case of mononitrotoluenes again, alcohol actually seems to inhibit the reduction. Hence it was put

forward as a mere probability, which we admit is based on indirect evidence, that alcohol is not likely to assist in the reduction of mononitro compounds with titanium chloride to such an extent as to render sulphonation unnecessary.

Possibly Dr. Knecht can show us wrong in this supposition, since it is based partly on his results.

We understand from the latter part of this note that the titanium method has undergone considerable development and that this is of such novelty that publication is undesirable, and can only regret if he is thereby debarred from making a full and illuminating reply.

We are glad to hear that titanium chloride of the grade of purity specified in his book can be obtained gratis. It would naturally be preferred on this account, since tin and stannous compounds cannot be obtained on such favourable terms.

In conclusion we can assure Dr. Knecht that we have no intention of discarding any useful method; least of all one which has been so carefully standardised as the reduction by titanium chloride.

Determination of Sugar in Baked Articles.

The following is the method for the determination of the amount of sugar in baked articles as settled at a Conference between the Government Chemist and representatives of the Society of Public Analysts and of Biscuit Manufacturers:—

1.—Preparation of sample.

A. *Biscuits and similar articles in a fairly dry condition.* The whole sample, or a thoroughly representative portion of it, is rapidly ground in a mortar or by passing through a mincing machine. The powder is mixed and used for analysis.

B. *Large cakes in a moist condition or with an outside crust.* A slice, not less than $\frac{1}{2}$ in. in thickness, is cut through the loaf, weighed, and dried at a moderately low temperature to a moisture content of about 10% when it can easily be ground. It is weighed again, ground, and mixed, and the powder used for analysis.

C. *Buns and small cakes in a moist condition.* Several buns or cakes are taken, weighed, broken into coarse pieces and dried at a low temperature to a moisture content of about 10%. The weight is again taken, the pieces ground, and the powder mixed, and used for analysis.

D. *Articles containing fruit (raisins, currants, dates, etc.) in which sugar naturally occurs.* A representative portion of the sample is weighed, broken rapidly on a sheet of paper, and the fruit removed and weighed. The drying of the cake from which the fruit has been removed is continued as under "B" or "C" and the fruit is reserved for the determination of the sugar.

II.—Analysis.

I. *Moisture.* A portion, about 5 grms., is weighed out from the prepared sample, and dried at 100°C . until the weight is constant. The loss in weight is corrected for the total loss in those cases in which preliminary drying previous to grinding has been carried out, and if fruit has been removed, to the original cake containing fruit.

II. *Sugars.* 10 grms. of the prepared sample is ground up with water in a mortar, and transferred to a 250 c.c. flask, using in all about 200 c.c. of cold water. The flask is shaken at intervals during 30 mins. The solution in the case of some articles, for example, certain kinds of biscuits, does not need a clearing agent. If it is necessary to use a clearing agent, basic lead acetate followed by sodium sulphate to remove excess of lead, or

alumina cream, or copper sulphate solution may be employed. The liquid in the flask is then made up to 250 c.c., filtered, and the sugars determined in the filtrate.

Fifty c.c. of the filtrate is measured into a 100 c.c. flask and inverted as follows:—5 c.c. of 38.8% hydrochloric acid is added and the flask placed in a water-bath maintained at 70° C. The solution should reach a temperature of 67° to 69° C. in 2½ to 3 minutes. It is maintained at 69° C. for 7 to 7½ minutes, the total period of heating being 10 minutes. It is then rapidly cooled, neutralised, made up to 100 c.c. and filtered.

The reducing sugar in the filtrate is determined either by gravimetric or volumetric means, the total copper-reducing power being calculated as cane sugar.

The quantity of "cane sugar" obtained is corrected to the original moisture of the sample and, if fruit has been removed, to the cake containing fruit. From the total quantity thus found, the sugar derived from added fruit in the case of fruit cakes is to be deducted.

This is estimated by determining the amount of sugar in the fruit removed from the cake, and the loss in sugar it has sustained, on the basis of the following average amounts of sugar in natural dried fruits, calculated on the *water-free* sample:—

	Total reducing sugars as sucrose.
Raisins	80
Currants	80
Figs	70
Dates (without stones)	70

A deduction of 3% (3 units) is made from the total amount obtained, for sugars naturally present in flour or derived from flour in course of baking.

To provide for variations in sampling, in methods of analysis, and in the amount of sugar in the different materials employed, an allowance of 2% (2 units) is made.

(Note.—In the case of samples which have been prepared from ingredients containing active malt flour or extract this method is not applicable.)

GOVERNMENT LABORATORY.

25th May, 1917.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Ferou 8. Paris (3e.)

Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Furnace heated by gaseous combustion. A. C. Ionides, jun., London. Eng. Pat. 106,546, June 21, 1916. (Appl. No. 8741 of 1916.)

IN furnaces of the type in which a combustible gaseous mixture is injected tangentially into a combustion chamber at such a velocity that firing back is prevented, the injecting nozzle opens into a wider port in the furnace wall so that the mixture passes through the port as a self-contained jet without impinging on the walls. The nozzle is converging, and is made of refractory material surrounded by a metal sleeve which is also connected with the gaseous fuel supply. Firing back of the jet is prevented by its isolation from the heated furnace wall and by conduction of heat away from the nozzle by the metal sleeve as well as by the velocity of the jet itself.—W. F. F.

Furnaces [for liquid fuel]. C. Zulver, London, and L. E. Smith, South Shields. Eng. Pats. (A) 106,703, and (B) 106,704, June 30, 1916. (Appl. Nos. 9239 and 9240 of 1916.)

(A) In a furnace adapted for liquid fuel, the fuel-supply opening in the furnace front is provided with an outer dome-shaped perforated baffle which is enclosed by a cylindrical cover, the outer circular plate of which is adjustable to control the admission of air. The fuel burners pass through the cover and baffle. Large horizontal air-supply tubes extending into the ash-pit are controlled by sliding doors in the furnace front, and the air passes back over the tubes to an opening in the front of the furnace and is thereby preheated. When solid fuel is used, the liquid-fuel fittings, preheating tubes, and firebar covering are removed.

(B) A furnace front is provided with a fuel-supply opening, 1, having an air passage, 2, surrounding the upper part. The upper wall of the passage is provided with air inlets, 3, controlled by a slide, 4, operated by a handle on the exterior of the furnace front. The lower wall of the passage is provided with openings, 6, and adjustable openings, 7.

Additional openings, 9, are regulated by pivoted doors, 10, operated by levers, 11, and the air supply to the underside of the firebars is controlled by dampers, 15. The operating handles of the

dampers, 15, and slide, 4, may be interconnected. Liquid-fuel burners may be attached to the furnace door, in which case all the air inlets are opened, but when solid fuel is used, the side openings, 7 and 9, are closed. In a modification, the passage, 2, is extended down to the floor of the furnace so as to cover the openings, 9.—W. F. F.

Furnaces for steam generators. G. E. Heyl, London. Eng. Pat. 106,707, July 11, 1916. (Appl. No. 9763 of 1916.)

IN a furnace of the type in which low-grade fuel containing sulphur, such as shale oil, is burnt,

absorbents for sulphur such as lime, iron, ferrie oxide, copper, or compounds thereof are placed between the furnace and the flues of a steam generator. The absorbent is placed on shelves arranged to form a tortuous passage through which the furnace gases pass from top to bottom. —W. F. F.

Furnaces: Means for discharging material from mechanical—. Huntington, Heberlein and Co., Ltd., and H. C. Bingham, London. Eng. Pat. 107,185, Mar. 15, 1917. (Appl. No. 3792 of 1917.)

TREATED material such as roasted sulphur-bearing ore is discharged from the furnace through a passage containing an air lock, to avoid admission of air to the furnace. An inclined discharge passage is closed by a flap at its outer end adjacent to the furnace outer wall. A closed shoot extending downward surrounds the end of the passage and is closed at its outer end by a flap having an adjustable counterweight, so that it opens only with a greater pressure than the inner flap.

—W. F. F.

Furnace for pulverous fuel. K. H. V. von Porat, Stocksund, Sweden. U.S. Pat. 1,229,685, June 12, 1917. Date of appl., July 15, 1913.

PULVERISED fuel is injected into the upper end of a channel of refractory material sloping downward into the furnace, and is ignited at the beginning of the supply or at intervals. The hot burnt gases leaving the lower end of the channel are cooled by passing backward through passages formed by a hood over the admission channel, and then pass forward between this hood and the surrounding firebox to the boiler or the like.—W. F. F.

Drying fruit, vegetables, herbs, chemicals, powders, seeds, minerals, and the like; Apparatus for—. F. Hewett, Anerley, Kent. Eng. Pat. 106,549, July 3, 1916. (Appl. No. 9291 of 1916.)

REMOVABLE trays, each comprising a gauze base attached to side rails, are arranged one above the other in a casing so that a flue is formed at one end. Hot air is introduced into this flue and passes over, under, and through all the trays simultaneously to an outlet at the other end. The trays may be horizontal or inclined, or the perforated bottoms may be inclined. Removable deflecting boards are provided above each tray to prevent moisture rising from one tray into the next, and the boards may carry corrugated metal sheets to condense and carry away moisture. Two tiers of trays may be placed side by side in a casing, the common central passage acting either as an inlet or an outlet flue for the hot air. Removable boards may be provided to close the inlet flue at any height, so as to enable any desired number of trays to be used.—W. F. F.

Dryer for sand, gravel, etc. W. H. Dance, Assignor to The Dyar Supply Co., Cambridge, Mass. U.S. Pat. 1,230,981, June 19, 1917. Date of appl., Dec. 21, 1916.

A DRUM with open ends rotates on a slightly inclined axis and is provided with internal longitudinal wings to raise and release the loose material which is fed into the upper end of the drum. A fixed burner projects into the lower end of the drum below a fixed heat-conducting surface which is heated by the flame. The wings adjacent to the hot surface are bucket-shaped, so as to discharge the loose material on to the surface, which is inclined laterally to discharge the material on to the bottom of the drum. The upper end of the drum is provided with a suitable outlet, so that condensed vapour is prevented from running back on to the material.—W. F. F.

Combustion products; Method of and apparatus for generating—under pressure. W. B. Vanderlip, London. Eng. Pat. 106,579, Oct. 3, 1916. (Appl. No. 14,046 of 1916.)

ENERGY is stored in a suitable reservoir by the compressed gaseous combustion products of the explosion of successive cartridges of nitroglycerin or dynamite. The cartridges contained in a vertical magazine are fed by the reciprocation of two releasing slides at the bottom into a horizontal barrel attached to the side of the gas reservoir. A feeding ram provided with a concentric firing pin is inserted into the barrel to push the cartridge forward to the firing position, and the ram is then locked in position and the firing pin operated by a hammer by means of interconnected gearing. The outlet of the barrel is provided with a conical lift valve carried by a framework provided with springs which normally maintain the valve closed. At the moment of firing the valve is lifted mechanically and the opening is completed by the explosion gases. The valve is then allowed to close under the action of the springs and the gas pressure in the reservoir, and the cartridge is withdrawn and ejected by known mechanism. The storage reservoir is double walled and the jacket is partly exhausted to provide heat insulation. A thermostat within the reservoir may control the valve of an injector whereby water is sprayed into the reservoir to augment the pressure by the generation of steam. The compressed gas may be used in a suitable engine, or, when the steam is omitted, for smelting purposes.—W. F. F.

Power; Process of employing heat for the production of—. S. M. Lillie, Philadelphia, Pa. U.S. Pat. 1,230,417, June 19, 1917. Date of appl., Apr. 15, 1914. Renewed July 17, 1916.

LIQUID is heated by bringing it into intimate contact with hot gases from the combustion of fuel in a closed vessel, and the uncondensed gases are separated and conveyed to a suitable motor operating at a lower pressure than that in the closed vessel. The pressure of the heated liquid is reduced to a point below the pressure at which the liquid will boil at the higher temperature, and both the vapour formed and the residual liquid are used for the production of power in a suitable motor. The residual liquid is then reheated and used again as described above.—W. F. F.

Separators; Centrifugal— and methods of working same. W. J. Gee, London. Eng. Pat. 106,669, May 31, 1916. (Appl. No. 7727 of 1916.)

IN centrifugal separators of the type described in Eng. Pats. 4155 of 1907 (this J., 1908, 227), 21,421 of 1909 (this J., 1910, 1239), and 9365 of 1915 (this J., 1916, 1206), a draining device is provided to enable the liquid remaining in the basket after the feed has been stopped to drain away before the rotation of the basket is stopped.—W. H. C.

Producing cold by the liquefaction of gaseous fluids; Process and apparatus for—. E. A. W. Jefferies and F. E. Norton, Worcester, Mass., U.S.A. Eng. Pat. 106,675, June 1, 1916. (Appl. No. 7797 of 1916.)

THE pressure on the liquid produced by liquefaction of the gas is maintained or increased and the liquid is partly evaporated under such pressure by the heat given out by the gas undergoing liquefaction. The vapour produced is then circulated through a heat exchanger through which the gaseous fluid before liquefaction is also circulated in an opposite direction. A "heat transfer fluid" is circulated through heat exchange apparatus to act as a carrier between the liquid of which the pressure is raised and the gas undergoing liquefaction. —W. H. C.

Gases; Process and apparatus for separating mixed

— F. E. Norton, Worcester, Mass., U.S.A.
Eng. Pats. (A) 106,676 and (B) 106,677, June 1,
1916. (Appl. Nos. 7798 and 7799 of 1916.)
(See preceding abstract.)

(A) A MIXTURE of gases is partially liquefied in a heat interchanging apparatus, and the gaseous portion is withdrawn and passed through a refrigerating engine and then through a coil in the rectifying vessel. It is then mixed with a portion of the already condensed liquid and passed through a pump, whereby the pressure is increased, and delivered into the rectifying vessel. (B) A separate liquid is circulated through a coil and an expansion valve by a compressor to transfer the latent heat from the gas being liquefied to the high-pressure fluid being rectified.—W. H. C.

Refrigeration. G. James, London, Eng. Pat. 106,868, June 8, 1916. (Appl. No. 8146 of 1916.)

LIQUID ammonia or other refrigerating medium is passed through a heat interchanger comprising concentric pipe coils through which the ammonia and the air to be cooled pass in opposite directions. The outlet for the ammonia is connected to an inverted U-tube, the other end of which is connected to a suitable mechanical exhauster and condenser, so that the ammonia is vaporised as a saturated vapour in the U-tube, and then condensed, without change of temperature or pressure. The liquid ammonia passes through an oil separator and a cooling coil and thence back to the heat interchanger. The circulation of the air to be cooled may be facilitated by a blower or fan. The liquid-cooling coil and the oil separator may be omitted if desired. Air at varying temperatures may be drawn from different points of the coil of the heat interchanger.—W. F. F.

Refrigerating method and apparatus. W. T. Hoofnagle, Glen Ridge, N.J., Assignor to Electro-Chemical Products Co., New York. U.S. Pats. 1,230,482 and 1,230,483, June 19, 1917. Dates of appl., July 8 and Aug. 6, 1915.

WATER is admitted intermittently to a vessel and caused to flow backwards and forwards in it. A current of air is caused to flow between the surface of the liquid and a parallel rotating surface, close to it, to vaporise the liquid. Air and vapour are withdrawn by an exhauster, the vapour condensed, and the air returned to the vessel.

—W. F. F.

Water cooling towers; Water distributing arrangement for —. Dansk Jernbetonkonstruktions Co. Danalith Aktieselskab, Copenhagen, Eng. Pat. 106,933, Oct. 19, 1916. (Appl. No. 14,901 of 1916.) Under Int. Conv., June 20, 1916.

In a water cooling tower, water overflows from a vertical pipe on to the centre of a reinforced concrete plate having large openings, each with a flange of adjustable height projecting upward. The water overflows into small vertical pipes projecting upward through the plate to an adjustable distance and carrying splashing plates below their lower ends. The water then trickles over the usual arrangement of cooling bars or grids. The cooling air passes upward over the grids and through the large openings in the plate. The openings for water and air are distributed uniformly over the plate, so that in every circular belt, or sector, the ratio of water to air openings is constant.

—W. F. F.

Filter-press. H. A. Vallez, Bay City, Mich. U.S. Pat. 1,227,983, May 29, 1917. Date of appl., Mar. 6, 1915.

A FILTER-PRESS comprises a number of filtering elements mounted upon a shaft and rotated within a casing. The cake is removed from the filter

elements by jets of water in the upper part of the casing and a scraper bar attached to the peripheries of the filter elements so that it travels in close proximity to the interior of the casing. The cake falls into a trough which extends below the casing and is moved to a central discharge opening by oppositely working conveyors.—W. H. C.

Evaporator. A. W. Waern, Assignor to International Process Co., New York. U.S. Pat. 1,228,855, June 5, 1917. Date of appl., Aug. 11, 1916.

AN evaporator for recovering soda ash consists of a tank divided into two chambers by a longitudinal hollow partition open at each end, and furnace gases are passed through "baffle wheels" which dip into and are rotated in the liquid in each chamber. The discharge opening is in the bottom of the hollow partition and both it and the discharge pipe are provided with scrapers.—W. H. C.

Leaching apparatus. U. Wedge, Ardmore, Pa. U.S. Pat. 1,229,839, June 12, 1917. Date of appl., Mar. 1, 1915.

MATERIAL to be leached is fed by a rotating system of pipes on to a series of shallow superposed pans, each having a false bottom. Two discharge pipes are provided for each pan, connected respectively to the spaces above and below the perforated false bottom. Each set of similar pipes is connected by valved connections to a common discharge main.—W. F. F.

Condensing apparatus. J. J. Brown, Newark, N.J. U.S. Pat. 1,230,557, June 19, 1917. Date of appl., July 31, 1914.

THE non-condensable vapour from a surface condenser, 11, is discharged by the conduit, 23, extending into the condenser and restricted at the outer end, 26. The condensed liquid is discharged

by the annular conduit, 25, which is restricted at a point adjacent to the end of the inner conduit. Steam is injected by the nozzle, 30, to compress the non-condensable vapour in the restricted end of the conduit, 23, and the compressed vapour, condensed liquid, and condensed water are mixed in the conduit, 21, leading to an air and condensed liquid pump, 16.—W. F. F.

Mixer and pulveriser. R. W. Christian, Manchester, N.C. U.S. Pat. 1,230,672, June 19, 1917. Date of appl., Apr. 21, 1917.

A CASING having a base of semi-circular section is provided near one end with a slotted discharge opening. Near this opening the sides of the casing are connected by a transverse arch, forming with the base a circular opening, within which a stationary pulveriser is mounted on yielding supports. The portion of the casing between the arch and the opposite end forms a mixing chamber, within which is a mixer mounted on a rotating shaft. The pulveriser comprises a central plate, to which are secured segmental pulveriser plates with outstanding pulveriser arms. The material is forced through the pulveriser by the mixer.

Catalysts; Process of regenerating — N. Sulzberger, New York. Eng. Pat. 105,057, Sept. 13, 1916. (Appl. No. 12,990 of 1916.) Under Int. Conv., Mar. 20, 1916.

SEE U.S. Pat. 1,199,032 of 1916; this J., 1916, 1097.

Cooling air, liquids, vapours, gases, and the like; Apparatus for — E. Josse and W. Gensecke, Charlottenburg, Germany. U.S. Pat. 1,228,930, June 5, 1917. Date of appl., Oct. 28, 1911.

SEE Fr. Pat. 436,241 of 1911; this J., 1912, 479.

Purifying and separating finely-divided substances; Method of — B. Schwerin, Assignor to Ges. für Elektro-Osmose, Frankfurt, Germany. U.S. Pat. 1,229,203, June 5, 1917. Date of appl., Jan. 5, 1912.

SEE Fr. Pat. 438,183 of 1911; this J., 1912, 649.

Separation of finely-divided substances from coarse and foreign matters; Method for — B. Schwerin, Assignor to Elektro-Osmose A.-G. (Graf Schwerin Ges.), Frankfurt, Germany. U.S. Pat. 1,230,524, June 19, 1917. Date of appl., May 13, 1915.

SEE Eng. Pat. 7590 of 1915; this J., 1915, 729.

Gases under pressure; Storing of — A. Stephenson, Assignor to Acetylene Illuminating Co., Lambeth. U.S. Pat. 1,230,531, June 19, 1917. Date of appl., Nov. 7, 1916.

SEE Eng. Pat. 106,406 of 1916; this J., 1917, 701.

Steam generation. W. A. Bone and J. W. Wilson, Leeds, and C. D. McCourt, Assignors to Radiant Heating, Ltd., London. U.S. Pat. 1,230,990, June 26, 1917. Date of appl., June 23, 1911. Renewed Nov. 18, 1916.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coke; Conditions of formation of — G. Charpy and M. Godchot. Comptes rend., 1917, 164, 906—908.

A METHOD is described for studying the coking properties of coals quantitatively and also the influence of temperature on the coking process. The coal under test is powdered to pass a sieve of 120 meshes and exposed to an atmosphere saturated with water vapour and at 18°—20° C., so as to define the humidity of the sample. The powder, compressed under a pressure of 5 kilos. per sq. cm., is filled into a tube or fireclay which is securely closed at the ends with iron plates. The tube and contents are introduced into an electrically heated furnace of such dimensions that the temperature is not thereby appreciably depressed.

Heating is continued 1 hour. The coke is produced in the form of a cylinder 12 mm. in diameter and 20 mm. in height, which can readily be subjected to a compression test, the result of which is taken as a measure of the quality of the coke produced. The results of experiments on three kinds of coal at different temperatures are given. The compressive strengths in kilos. per sq. cm. are the mean values of six determinations, the extreme values of which are given in brackets:

Coking temperature.	St. Eloy coal.	Ferrières coal.	Noyant coal.
650° C.	19.85 (17, 22)	19.0 (17, 21)	100 (94, 105)
800° C.	32.9 (29, 36)	30.5 (21, 34)	93.6 (90, 98)
1000° C.	38.7 (35, 42)	45.0 (42, 49)	36.3 (33, 39)

The variations with temperature are thus much greater than the experimental error and are not, it is interesting to note, always in the same direction. On modifying the methods of heating, other changes are produced. Thus the Noyant coal, if heated for a time at 650° C. followed by a gradual rise of temperature to 1000° C., gives a coke having a compressive strength of 130 kilos. per sq. cm., while the coke from the St. Eloy coal is not appreciably improved by the same treatment. The authors advocate the determination for each coal of the thermal treatment which leads to the best results in the coke.—H. J. H.

Carbonising results with Glover-West vertical retorts at Macclesfield. J. E. Blundell. Gas J., 1917, 139, 106.

THE yield of gas from a Glover-West vertical gas retort plant has been increased by 25% by passing steam through the charge in the retort. In test runs with a mixture of Yorkshire, Derbyshire, and Staffordshire coals (volatile matter 37, ash 5%, yields of 15,500 cub. ft. and 15,200 cub. ft. of gas (tar-washed) of 510 and 508 B.Th.U. (gross) respectively were obtained, and during two months the yield of tar was 15.7 galls. and of ammoniacal liquor (10 oz.) 33.35 galls. The steam is supplied from boilers working at 100 lb. per sq. in. pressure and is reduced to 5—10 lb. pressure in the coke chambers, to each of which it is admitted through a nozzle of $\frac{1}{2}$ in. bore; the rate of discharge of the coke is reduced 10%. It is important that the heating of the retorts be so controlled that the highest temperature is towards the lower end of the carbonising portion of the retort, otherwise the carbon dioxide content of the gas is unduly high. Tests have indicated that by increasing the free space at the upper or outlet end of the retort, the content of heavy hydrocarbons in the gas is increased.

Cracking of petroleum in the liquid phase. R. Cross. Met. and Chem. Eng., 1917, 16, 643—645.

THE method recommended consists in applying heat to the petroleum in the liquid phase, maintaining a pressure of about 30 atmospheres and a temperature of not more than 400° C. The advantages of this method over cracking in the vapour phase are:—(1) greater yield and better quality of the product; (2) selective action on the heavy hydrocarbons with freedom from further cracking of the portion in the vapour phase; (3) the gasoline is removed from the reaction zone as fast as it is formed; (4) high heat economy; (5) carbon is deposited in the suspended condition and not on the walls of the tubes; (6) high oil capacity with small plant; (7) perfect temperature control; (8) rapid and complete absorption of heat from the furnace, and (9) convenient continuous or intermittent working of the process. The only serious disadvantage is the high pressure required with possible danger of explosive destruction of the apparatus.—W. H. P.

Liquid fuels; Spontaneous ignition temperatures of —. H. Moore. Engineer, 1917, 561.

THE spontaneous ignition temperature (this J., 1917, 109) can be used as a means of deciding the maximum and minimum engine compressions

suitable on petrol and Diesel engines respectively when burning any given liquid fuel. By plotting the calculated values of temperature and compression pressure, using the exponential, $\eta = 1.35$, a curve E F (see fig.) is obtained which shows the theoretical maximum compression practicable in a petrol engine, and which is also the minimum limit for the compression practicable in a Diesel engine, assuming that the temperatures represent the ignition points of the fuels. As several conditions cause interference with the working of this rule, the practical limits do not coincide with the curve E F. To obviate this difference the practical curves, C D and A B, applicable to engines operating on the constant volume and constant pressure cycles respectively, have been constructed from the results of engine trials on fuels of known ignition temperature. By the use of these curves the compression pressure of internal combustion engines can be directly ascertained by determining the ignition point of a fuel. Motor spirits of petroleum or shale origin do not vary in ignition point to any large extent. Benzol, alcohol, kerosene, and naphthalene possess widely varying ignition points which make adjustment of the engine compression advisable. Fuel oils derived from coal tar possess high ignition points, and mixtures are being marketed containing petroleum oils together with coal tar distillates. Such oils, if suitable as regards general chemical analysis, require examination as to ignition point; if the ignition temperature be high it will be necessary to make adjustment on Diesel engines, as otherwise in cold weather difficulty in starting will be experienced. By determining ignition points of mixtures of kerosene with tar oil and of Mexican fuel oil with tar oil, curves of ignition point against compression have been constructed. Mixtures containing half tar oil and half petroleum products have ignition points which are lower than the mean of the values for the two constituents. The admixture of a small quantity of either oil to the other causes the mixture to possess an ignition point differing widely from that of the main constituent.—F. W. A.

Cheap production of alcohol. Breckler. See XVIII.

PATENTS.

Waste products of coal and other fuels; Conversion of — into inflammable gas for consuming smoke in furnaces. A. E. Shill, S. Diggle, and G. B. Scott, London. Eng. Pat. 106,775, Nov. 24, 1916. (Appl. No. 16,854 of 1916.)

SMOKE, waste gases, and the like are withdrawn

from a flue by means of a steam jet operating in a pair of funnels arranged to act as an injector, and the mixture of steam and smoke is injected behind and above the fire along with superheated steam, producing an additional carbon monoxide flame of intense heat.—J. E. C.

Coke-ovens; Regenerative —. J. A. Roelofsen, Harrogate. Eng. Pat. 106,905, Aug. 10, 1916. (Appl. No. 11,318 of 1916.)

IN a regenerative coke-oven the coking chambers are arranged side by side and are heated by superposed horizontal flues, *c*, in the walls between them. Each flue is provided with gas supply

burner nozzles, *j*, at each end, which are used alternately. The air supply passes through an air chamber, *i*, to a regenerative chamber, *h*, of known form. The heated air passes through a horizontal flue, *g'*, to a vertical flue, *g*, which communicates with all the heating flues, *c*. The combustion gases are exhausted through the opposite flues, *g*, *g'*, and chambers, *h*, *i*, until these are heated to the required temperature. The air circulation is then reversed and the opposite set of burner nozzles, *j*, is used. When gas of low calorific value, such as generator or blast-furnace gas, is used, the regenerators, *h*, are placed above the chambers, *i*, and an additional pair is provided at each end through which the gas supply is passed to preheat it.—W. F. F.

Coke-ovens; Regenerative —. E. Hurez, Petit Couronne, France. Eng. Pat. 107,178, Jan. 26, 1917. (Appl. No. 1344 of 1917.)

IN a regenerative coke oven the walls are formed of flues, each adjoining pair of flues being traversed simultaneously, one by gases in intense combustion, the other by the burned gases, the direction of flow being periodically reversed. The flues are separated by partitions composed of hollow bricks enclosing a heat-insulating layer of air to concentrate the effective heat within the coking chamber.—J. E. C.

Retorts employed in the manufacture of illuminating gas from coal; Means for effecting the removal of the carbon deposit from —. W. T. Bark, Tenterden, Kent. Eng. Pat. 106,910, Aug. 21, 1916. (Appl. No. 11,830 of 1916.)

IN a retort for the manufacture of coal gas, the deposit of gas carbon is removed by burning. The bottom of the retort is provided with refractory bricks of flat, arch, channel or other shape, forming a longitudinal air conduit communicating with an opening in the door and extending nearly to the farther end of the retort. A current of air is drawn through the conduit into the retort to burn the carbon, and the combustion products are withdrawn at the charging end of the retort. A supplementary door may be provided having the

necessary air opening and a sight hole, or these may be formed in the ordinary door and closed when not in use.—W. F. F.

Vertical [gas retort] bench. P. Plantinga, Cleveland, Ohio. U.S. Pat. 1,228,175, June 5, 1917. Date of appl., July 12, 1915.

A VERTICAL retort bench comprises a gas producer, an oven beside the producer, and a recuperator below the producer and oven, the whole forming an integral masonry structure. Gas passes from the top of the producer to the bottom of the oven, and the products of combustion pass from the top of the oven downwards through the recuperator, in the opposite direction to the secondary air, which meets the gas supply at the bottom of the oven.—J. E. C.

Furnaces and gas producers; Combined—. R. F. Hislop, Paisley. Eng. Pat. 106,513, Mar. 24, 1916. (Appl. No. 4368 of 1916.)

A GAS producer forming part of a heating furnace for drying, annealing, or melting, heating galvanizing baths, enamelling muffles, or steam boilers, is provided with a special arrangement of secondary air-supply conduits. Air at 8—10 oz. pressure is preheated by passing from a supply main through branch pipes and conduits in the producer or furnace walls to the combustion chamber. In a modification, air may be induced into the conduits by a small jet of air or steam at 40—80 lb. pressure. Air at 8—10 oz. pressure may also be delivered directly to the combustion chamber.—W. F. F.

Shaft furnaces such as gas producers; Feeding mechanism for—. *Charging apparatus for gas producers.* The International Construction Co., Ltd., and A. Sahlin, London. Eng. Pats. (A) 106,943 and (B) 106,977, Nov. 19, 1916, and Mar. 19, 1917. (Appl. Nos. 16,125 of 1916 and 3988 of 1917.)

(A) IN feeding mechanism for shaft furnaces such as gas producers, of the type in which a rotating hopper is provided with an eccentric inclined distributing nozzle projecting into the furnace, the nozzle is made adjustable in length to compensate for the burning off of the extremity. For example, one or more bars resting on the lower wall of the nozzle and projecting beyond the outlet, may be moved forward to any desired distance, or completely withdrawn for renewal, by screwed rods operated from outside. The adjustment may be effected during the working of the apparatus. (B) The feeding apparatus described in (A) is combined with a horizontal rotating measuring drum for the fuel. A charge is deposited intermittently on the fuel bed, and the measuring drum and feeding mechanism are so geared that the charges are not fed in the same position during successive rotations of the feeding nozzle.—W. F. F.

Gas; Manufacture of—. J. Bueb, Dessau, Germany. U.S. Pat. 1,228,879, June 5, 1917. Date of appl., Oct. 11, 1913.

COAL is distilled in a vertical retort at a temperature approximating to the melting point of silica, and water vapour is admitted towards the end of the distillation, whereby water-gas is generated and reacts with the tar remaining in the coke.—J. E. C.

Gas producer. L. F. Burger, Beloit, Wis., Assignor to International Harvester Corporation. U.S. Pat. 1,230,558, June 9, 1917. Date of appl., June 30, 1913.

IN a gas producer a tuyère is arranged centrally on the top of a generating chamber. A fuel-charger is fitted within the tuyère and spaced

apart from the sides. An air and a steam pipe on the side of the tuyère communicate with the interior.—J. E. C.

Fuel gas; Method of producing—. M. Sklovsky, Assignor to Deere and Co., Moline, Ill. U.S. Pat. 1,229,338, June 12, 1917. Date of appl., Sept. 8, 1914.

AIR is preheated to a temperature high enough to vaporise fuel oil and is then passed through a vaporising chamber at a high velocity. Fuel oil is introduced into the stream of air, and the mixture, in correct proportion, passes to the combustion chamber at a velocity sufficient to prevent backfiring of the flame into the vaporiser.—J. E. C.

Hydrocarbon gases; Process for improving the quality and yield of—. J. G. Davidson and R. W. Ford, Vancouver, B.C. U.S. Pat. 1,229,042, June 5, 1917. Date of appl., Nov. 29, 1915.

THE gas is subjected to the action of a high-tension silent electric discharge so as to convert hydrocarbons of high molecular weight into those of lower molecular weight, and increase the percentage of fixed hydrocarbons and the final volume of the gas.—W. R. S.

Refining liquids and gases; Apparatus for—. J. N. Wingett, Assignor to W. A. Haggott, Denver, Colo. U.S. Pat. 1,229,189, June 5, 1917. Date of appl., June 21, 1915.

MATERIAL to be treated is fed through a combustion chamber to an inner concentric "treatment" chamber which contains a hydrometer. Heavy oil is automatically discharged through a valve in the bottom of the treating chamber, which is operated by electromagnetic means controlled by the vertical movement of the hydrometer as the density of the oil varies.—W. F. F.

Combustible fluids; Process of manufacturing—. J. R. Rose, Edgeworth, Pa. U.S. Pat. 1,230,226, June 19, 1917. Date of appl., Nov. 29, 1915.

A LIQUID or gaseous hydrocarbon is injected into a generator by a stream of hydrogen under pressure; a liquid hydrocarbon of a different series is also introduced into the generator, and the mixture of the three fluids is subjected in the generator to the action of highly heated refractory material. The resulting gaseous fuel is freed from carbon, scrubbed, and then enriched by conducting it through liquid hydrocarbon.—J. E. C.

Motor fuel for use in high-speed internal combustion engines. W. A. Hall, London. Eng. Pat. 106,876, June 16, 1916. (Appl. No. 8503 of 1916.)

A FUEL suitable for use in high-speed internal combustion engines consists of equal parts of an uncracked saturated hydrocarbon of the paraffin series boiling from 140° C. to 230° C., and a partly unsaturated hydrocarbon spirit produced by cracking as described in Eng. Pat. 24,491 of 1913 (this J., 1915, 216).—W. F. F.

Hydrocarbons; Treatment of—. H. Rostin and G. F. Forwood, London. Eng. Pat. 107,034, May 15, 1916. (Appl. No. 6926 of 1916.)

TO convert hydrocarbons of high boiling points into products of low boiling points, the heavy hydrocarbon, in the form of vapour, is mixed with hydrogen sulphide and brought into contact with a substance such as heated copper, capable of liberating the hydrogen of the hydrogen sulphide. The nascent hydrogen combines with the vapours of any unsaturated hydrocarbons produced. The copper sulphide produced may be treated with gases rich in hydrogen, forming hydrogen, sulphide and copper.—J. E. C.

Hydrocarbons; Synthetic production of—L. B. Cherry, Kansas City, Mo. U.S. Pat. 1,229,886. June 12, 1917. Date of appl., Feb. 21, 1916.

A HYDROCARBON of a relatively high gravity is produced from one of comparatively low gravity by subjecting the latter, in a hot vaporised state, to the silent discharge of a high frequency bipolar oscillating electric current in the presence of a heated and gaseous hydrogen-supplying agent.

—J. E. C.

[*Paraffin wax*] *candleslock*. R. Philip, Bofors, Sweden. U.S. Pat. 1,229,132, June 5, 1917. Date of appl., July 29, 1916.

THE material consists of paraffin wax and salicylic acid, with or without the addition of stearin.

—C. A. M.

Petrol and heavy oils; Process and apparatus for employing—in internal combustion engines. J. de Ferry, Paris. Eng. Pat. 106,963, Jan. 31, 1917. (Appl. No. 1573 of 1917.) Under Int. Conv., Nov. 14, 1916.

Coke oven; Method and apparatus for regulating the distribution of the heating gases among the heating flues of a regenerative—L. Wilputte, New Rochelle, N.Y., U.S.A. Eng. Pat. 106,953, Dec. 14, 1916. (Appl. No. 17,997 of 1916.)

Peat and the like; Preparing—for distillation. W. L. St. J. Prioleau, London. Eng. Pat. 106,636, Apr. 14, 1916. (Appl. No. 5512 of 1916.)

APPARATUS for obtaining volatile products from carbonaceous materials containing a considerable quantity of moisture, comprises an upper enclosed compartment acting as a preliminary drying and heating appliance, and a lower closed retort in which distillation is completed. The material traverses the upper section by means of a conveyor belt and scrapers and is then fed into the lower section along which it is transported by a screw conveyor. The vapours evolved are withdrawn at successive points in both sections and separately condensed.—J. E. C.

Filament; Ductile—O. M. Thowless, Assignor to A. J. Thowless, Newark, N.J. U.S. Pat. 1,226,925, May 22, 1917. Date of appl., Aug. 9, 1915.

A BODY of refractory metal powder is sintered at a high temperature in an atmosphere of hydrogen and the vapour of a halogen salt of tungsten, so that the metal contained in the halogen salt permeates and fills up the spaces between the particles of metal powder. The heating is continued until the whole mass is formed into a solid body, which is worked into a fibrous structure and reduced to a filament.—B. N.

Self-lighting gas mantles; Production of—J. G. Gotty, Jacksonville, Fla., Assignor to Gotty Gas Lighting Co. U.S. Pat. 1,227,259, May 22, 1917. Date of appl., Aug. 29, 1916.

A COMPOSITION containing platinum black and finely-divided particles of platinum as a catalytic agent, with a solvent comprising alcohol, glycerol, and dextrose, is used for making self-lighting gas mantles.—B. N.

Incandescence lamps; Method of making [electric]—W. D. Coolidge, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,230,869, June 26, 1917. Date of appl., Nov. 7, 1910.

III.—TAR AND TAR PRODUCTS.

Phenol; Determination of—in crude carbolic acid and tar oils. J. M. Weiss and C. R. Downs. J. Ind. Eng. Chem., 1917, 9, 569—580.

THE oil, if dirty, should be distilled in a copper tar-still, and the weight of total distillate recorded. *Extraction of the acids*. A weight of oil containing 300 to 350 grms. of acids is shaken with about 300 c.c. of 20% sodium hydroxide solution, the mixture allowed to stand 15 to 30 mins., and the aqueous layer drawn off into another separating funnel. The residual oil is shaken successively with 3 more portions of 200 c.c. each of the alkali solution and the alkaline extracts are added to the first extract. In the case of crude acid 300 to 350 grms. is dissolved in 800 c.c. of the sodium hydroxide solution, which is then treated as above. Should the acids be tarry they must be distilled before being dissolved in the alkali solution. *Purification of the carbolate*. The united alkali

FIG. 1

extracts are extracted with five successive portions of 100 c.c. of pure benzene, the benzene extracts washed twice with 50 c.c. of water, and the washings added to the carbolate solution, which is then gently boiled until free from any odour of benzene. Any odour of creosote at this stage indicates insufficient washing of the solution. **Acidification.** The purified carbolate is treated in a separating funnel with 25% sulphuric acid (sp. gr. 1.21), the temperature being kept below 40° C. during the acidification, and care being taken to add not more than a slight excess (5 to 10 c.c.) of the acid. The funnel is allowed to stand until the lower layer of sodium sulphate solution is clear (3 to 4 hours), and this layer is then drawn off, and extracted three times with successive portions of 100 c.c. of pure benzene. The benzene extract is shaken with two or more portions of 25 c.c. each of 20% sodium hydroxide solution, the alkali extract heated to expel benzene, and rendered slightly acid with sulphuric acid, and the separated acids added to the main portion of acids. The weight of the total quantity of wet acids obtained is then recorded. **Fractional distillation.** This is effected in a 500 c.c. round-bottomed short-necked flask, which is connected with a standard 12-pear still head, and a Barrett trough type condenser with a 24-in. tube. The thermometer should be graduated from 170° to 225° C. in $\frac{1}{2}^{\circ}$ C. and should be accurate to $\frac{1}{2}^{\circ}$ C. when totally immersed. Its dimensions should be as follows:—Total length, less than 380 mm.; bulb length, 20 to 25 mm.; 170° mark to bottom of bulb, 70 to 80 mm.; scale length 170°—225° C., 270—280 mm.; stem diameter, 5 to 7 mm.; and bulb diameter, 4 to 5.5 mm. The flask is supported over a burner on $\frac{1}{4}$ in. asbestos board 6 in. square, with an opening 3.5 in. in diameter in the middle, and it is surrounded by a circular asbestos shield about 3½ in. high, whilst a piece of asbestos board with a hole cut for the neck of the flask forms the top of the screen. **Mode of distillation.**

The distillation is carried out at the rate of one drop per sec., the distillate being received in a separating funnel until the temperature has reached 170° C. The distillation is then interrupted, and sufficient salt is added to the contents of the separating funnel to cause any acids present to rise to the surface. These are separated and

FIG. 2

returned to the distillation flask, which is then weighed so as to obtain the weight of dry acids. The distillation is now renewed, the first drops of acid and water being collected in a small separating funnel, and when the last drop of water has distilled, the distillate up to 190° C. is received in a small weighed flask, into which is also introduced the acid separated from the first drops of distillate. A second fraction (190° to 202° C.) is collected in a 250 c.c. flask, and at 202° C. the distillation flask is replaced by this flask. This fraction is now redistilled, after drying the condenser tube, and

the distillate is collected in the weighed flask containing the first fraction (to 190° C.). The distillation is continued up to 197° C., and the flask containing the combined fraction is weighed and kept well closed. *Testing the fraction.* The sp. gr. is determined by means of a Westphal balance, and the solidifying pt. as follows:—The fraction is poured into a test tube 5 to 6 in. long by 1 in. internal diameter so as to form a layer of 2 in. This tube is clamped vertically to a depth of 3 in. in a beaker containing 500 to 600 c.c. of water. A standard 0°–80° C. thermometer accurate to at least 0.1° C. is clamped with its bulb in the centre of the test-tube 0.5 in. from the bottom, and the liquid is stirred with a wire agitator surrounding the thermometer. The approximate solidifying pt. is taken, the contents of the tube remelted, the water in the beaker brought to a temperature 4.5° to 5.5° C. below the approximate solidifying pt., and a fresh determination is made with constant stirring until the maximum rise of temperature is obtained. Identical results should be obtained in duplicate tests. From the values obtained for the solidif. pt. and sp. gr., the phenol content may be ascertained by reference to the annexed curves. If they do not fall within the determination area it is best to mix the fraction with pure phenol (solidifying pt. at least 40.4° C.), so as to bring the tests within the range.—C. A. M.

Maplewood creosote; Toxic action of — and of some of its constituents and derivatives on a wood-destroying fungus. E. J. Pieper, S. F. Aree, and C. J. Humphrey. *J. Ind. Eng. Chem.*, 1917, 9, 566–569.

CULTURES of *Fomes annosus* were made on nutrient agar to which had been added measured quantities of maplewood creosote (this *J.*, 1917, 638) or of constituents thereof. It was found that the creosote had a high toxic coefficient, practically identical with that of beechwood creosote, which it also closely resembles in composition. The toxic action is due to the presence of carbocyclic compounds containing free hydroxyl groups or the corresponding methoxyl groups. The growth of the fungus was prevented by 0.05% of the alkalisoluble portion of the creosote, which is thus twice as toxic as the creosote itself, four times as toxic as the neutral oil, and seven times as toxic as coal-tar creosote. The lethal doses of the fractions distilling at 195° to 230° C. and 230° to 265° C. were practically the same as in the case of the creosote, but the fraction of higher b.pt. was somewhat more toxic than the fraction of lower b.pt. This was due to the greater proportion (80 to 85%) of phenols in the higher than in the lower fraction (65 to 70%). The higher fraction consists mainly of trihydric phenols, notably the dimethyl ether of pyrogallol and its homologues, whilst the lower fraction largely consists of mono- and di-hydric phenols, especially cresol, guaiacol, and creosol.

—C. A. M.

Condensations in the aromatic series by means of heat. H. Meyer and A. Hofmann. *Monatsh. Chem.*, 1916, 37, 681–722. *Z. angew. Chem.*, 1917, 30, Ref., 131–135.

THE vapours of the substances under investigation were heated to 700°–800° C. by an electrically heated platinum wire. Toluene yielded dibenzyl at a dull red heat, and, at a bright red heat, stilbene with some anthracene and a substance giving terephthalic acid on oxidation. At the lower temperature *p*-xylene gave *p*-dixyl and products oxidising to terephthalic and *p*-toluic acids, and gave *p*-dimethylstilbene at the higher temperature. Mesitylene and ethylbenzene yielded limesityl and stilbene respectively. Dibenzyl gave large quantities of anthracene, some stilbene,

very little toluene, and no phenanthrene. Fluorene was obtained from diphenylmethane, benzaldehyde and benzene from benzophenone, carbazole from diphenylamine, and naphthalene from α -dinaphthylamine. Naphthalene when heated at a dull red heat yielded principally $\beta\beta$ -dinaphthyl with a little of the $\alpha\alpha$ -isomer; at a higher temperature the yield of the latter was increased. Diphenyl yielded 4,4'-diphenylbiphenyl. The so-called "crackene" isolated from the red tarry substance obtained in the "cracking" process, is not identical with either benzerythrene or 4,4'-diphenylbiphenyl, but yields picene on purification. Pure benzerythrene and picene dissolve in concentrated sulphuric acid to colourless solutions; the green coloration used as a test is due to impurity.—F. C. T.

Phenyl- α -naphthylamine; Preparation of —. M. Katayama. *Kogyo-Kwaaku-Zasshi (J. Chem. Ind., Tokyo)*, 1917, 20, 353–365.

STREIFF's method of preparing phenyl- α -naphthylamine by combination of α -naphthylamine hydrochloride and aniline is tedious and gives a relatively poor yield. The author made experiments to ascertain the most suitable conditions for preparing the base by Friedländer's method of condensing aniline with α -naphthol in presence of a dehydrating agent. Under the following conditions a yield of 64% of the theoretical quantity of phenyl- α -naphthylamine (calculated on the α -naphthol used) is obtained. An intimate mixture of α -naphthol (1 mol.), aniline (2 mols.), and calcium chloride (1 mol.) is placed in an autoclave, which is heated for 10 hours at 300° C. The product is treated with boiling water to remove calcium chloride, with hydrochloric acid to remove uncombined aniline, and with caustic soda to remove uncombined α -naphthol, and is then distilled *in vacuo* in a current of carbon dioxide or hydrogen. After crystallising from alcohol, the phenyl- α -naphthylamine melts at 60° C.

Secondary arylamines from primary amines; Separation of —. J. Thomas. *Chem. Soc. Trans.*, 1917, 111, 562–572.

THE method is based on the observation that if a crude preparation of a secondary arylamine, *e.g.*, ethyl-*o*-toluidine, be heated with ethyl oxalate, no combination with the secondary amine takes place but that any primary amine present, *e.g.*, unchanged *o*-toluidine, readily reacts with the oxalic ester at the boiling point, giving a mixture of *o*-tolylloxamic ester and di-*o*-tolylloxamide in proportions depending on the duration of heating; the ethyltoluidine can then be readily separated by fractional distillation from the high-boiling products of the reaction of the toluidine with the oxalic ester. In practical use, the mixture of secondary and primary amines, distilled once to separate other impurities and containing about 13% of primary amine, is heated for 4–6 hours with 30% of its weight of oxalic ester, and the product fractionated. The fraction distilling up to 200° C. contains chiefly the excess of oxalic ester but contains also some of the base; the ethyltoluidine distilling at 200°–230° C. contains about 3% of the primary amine, which may be reduced to less than 1% by a second treatment with oxalic ester. In the case of secondary arylamines which are not readily separated from ethyl oxalate by distillation, owing to similarity of boiling points, butyl oxalate may be used with satisfactory results. The method has been employed also for the purification of ethylaniline, ethyl-*p*-toluidine, and monomethylaniline, in the last case with the use of butyl oxalate. It is likewise applicable for removing primary amines from tertiary bases.—J. F. B.

[*Anthraquinone derivatives*;] *Reduction [of —] in concentrated sulphuric acid solution by means of aluminium powder.* A. Eckert and R. Pollak. *Monatsh. Chem.*, 1917, **38**, 11—17. *J. Chem. Soc.*, 1917, **112**, i., 345—346.

THE authors have studied the reaction described in Ger. Pats. 190,656 and 201,512, by which anthraquinone derivatives are reduced in concentrated sulphuric acid solution by either copper or aluminium powder. In order to carry out the reduction, the substance is dissolved in 20—30 times its weight of concentrated sulphuric acid, and to the well-cooled mixture one-fifth of the weight of substance of aluminium powder is slowly added with continuous shaking and cooling. The end of the reaction is indicated by foaming. When the reduction is complete, the mixture is poured into cold water and the product extracted with a suitable solvent. In this way, anthraquinone has been reduced to anthraquinol and anthrone; benzophenone to β -benzopinacolin; benzoylbenzoic acid to the dilactone of dihydroxytetraphenylethanedicarboxylic acid. If the reduction is effected with the further addition of acetic acid or benzoic acid or their anhydrides, the products are either the diacetyl or dibenzoyl derivatives of the reduced substance. Acridone cannot be reduced by the above method. *p*-Chlorobenzoylbenzoic acid when reduced by aluminium powder yields the corresponding dilactone. When the dilactone of dihydroxytetraphenylethanedicarboxylic acid is heated with 20% fuming sulphuric acid for three hours at 180° C., it is converted into sulpho- β -anthraquinonecarboxylic acid.

PATENTS.

Tar dehydration and ammonia distillation plant; Combined —. F. L. Ball, Maidstone, and H. K. Hiller, Westminster. Eng. Pat. 106,642, May 16, 1916. (Appl. No. 6974 of 1916.)

AN apparatus for separating, dehydrating, or distilling emulsions, solutions, or mixtures of liquids of different specific gravity, such as tar, or debenzolising oil and other like fluids, or solutions of gases such as ammoniacal liquor, etc.

The still is heated by direct fire, and is designed so that priming or frothing is avoided. Vertical "staggered" deflector plates, F, form zigzag channels in the still, and the tops of hollow cast iron heat dispersers, G, placed in the channels, form tables on which the heated liquid, I, is spread in a thin film; the vapours escape by the pipe, D. The temperature of the liquid entering from B is progressively raised until it reaches the outlet, C, so that the vapours are liberated fractionally. The fire gases pass through flues, E, beneath the still.—F. W. A.

Distilling coal-tar on coal-tar pitch and products derived therefrom; Method of —. P. C. Reilly, Indianapolis, Ind. U.S. Pat. 1,230,782, June 19, 1917. Date of appl., Mar. 28, 1914.

COAL-TAR or coal-tar pitch is heated to about 1000° F. (about 540° C.) in a still, which is raised to an even temperature over its entire surface by a heated atmosphere. Dry coke is left as residue in the still, and the products of distillation comprise an orange-coloured mass waxy at 70° F. (21° C.) and a hard garnet-coloured product, brittle at 70° F. and of sp. gr. not less than 1.22.—F. W. A.

Toluol; Manufacture of —. O. B. Evans, Assignor to The United Gas Improvement Co., Philadelphia, Pa. U.S. Pat. 1,230,087, June 12, 1917. Date of appl., Feb. 24, 1915.

NAPHTHA "of gas-drip origin" is heated to a temperature sufficiently high to increase materially the percentage of toluene, in a chequer-brick chamber preheated by internal combustion of water-gas, and the toluol is recovered from the mixture of hydrocarbon gas and toluol vapour produced.—F. W. A.

Aromatic hydrocarbon hydroxy compounds; Cyclic process of making —. L. M. Dennis, Ithaca, N.Y. U.S. Pat. 1,227,894, May 29, 1917. Date of appl., July 14, 1916.

HYDROXY derivatives of aromatic compounds, e.g., phenol, are obtained by a cyclic process by the interaction of an aqueous solution of an aromatic sulphonic acid free from sulphuric acid, e.g., benzenesulphonic acid, with the alkali salt of a hydroxy compound, e.g., sodium phenoxide, thus producing the free hydroxy compound, e.g., phenol, and the alkali salt of the sulphonic acid; fusion of the latter with alkali hydroxide gives alkali phenoxide, which is used again as above described.—F. W. A.

Sulphonic acid from sulphuric acid; Method of separating aromatic — and of obtaining it in solid form. L. M. Dennis, Ithaca, N.Y. U.S. Pat. 1,228,111, June 5, 1917. Date of appl., Nov. 20, 1916.

THE sulphonic acid of an aromatic hydrocarbon, e.g., naphthalene- β -sulphonic acid, is separated from sulphuric acid and obtained in solid form by treating the mixture with a warm organic solvent, e.g., toluene, and cooling the separated solution of the sulphonic acid.—F. W. A.

Sulphonic acid of a hydrocarbon of the aromatic series; Method of separating a — from sulphuric acid and converting the sulphonic acid into a salt. L. M. Dennis, Ithaca, N.Y. U.S. Pat. 1,229,593, June 12, 1917. Date of appl., Nov. 6, 1916.

AN aromatic sulphonic acid, e.g., benzenesulphonic acid, is extracted from its mixture with sulphuric acid by means of an insoluble organic solvent, e.g., benzene, the solution is treated with water, and the aqueous solution is treated with a suitable compound to form a salt of the sulphonic acid.—F. W. A.

Treatment of hydrocarbons. Eng. Pat. 107,031. See IIA.

Synthetic production of hydrocarbons. U.S. Pat. 1,229,886. See IIA.

IV.—COLOURING MATTERS AND DYES.

Diazo-oxides (diazophenols); Constitution of —. H. G. T. Morgan and H. P. Tomlins. *Chem. Soc. Trans.*, 1917, **111**, 497—506. (See also this J., 1915, 653.)

THE sulphonic acids of the *o*-, *m*-, and *p*-amino-

phenols yield diazo-derivatives crystallising with 1 mol. of water. The *o*-diazo-derivative and its salts are yellow substances in which internal condensation has taken place between the phenolic and diazo-groups, leading to an *o*-diazo-oxide which may alternatively be represented as an *o*-quinonediazide. The diazo derivative of *p*-aminophenolsulphonic acid is a colourless internal diazonium sulphonate which gives yellow salts on the addition of 1 mol. of an alkali or organic base; these salts are *p*-diazo-oxide or *p*-diazo-quinone derivatives. The *m*-diazo-derivative is an internal diazonium sulphonate, colourless when pure, but far less stable than the *p*-derivative. On the addition of an alkali or organic base it shows no tendency to form salts of the *m*-diazo-oxide type, but decomposes rapidly with evolution of nitrogen, and the decomposition product (resorcinol-4-sulphonic acid) couples with the still undecomposed diazonium sulphonate to form an azo dyestuff.

—J. F. B.

PATENTS.

Soluble colour compound. W. Beckers and I. Dreyfus, Brooklyn, N.Y.. Assignors to W. Beckers Aniline and Chemical Works. U.S. Pat. 1,228,089, May 29, 1917. Date of appl., July 6, 1914.

A NEUTRAL alkali chromate is dissolved in glucose, heated until no chromic acid is present, and a solution of a mordant colour is added to obtain a compound of the mordant colour soluble in neutral, alkaline, and acidulated water.—F. W. A.

Acridine series; Cadmium compounds of the — and a process of making the same. P. Hüßy and M. Hartmann. Assignors to Soc. Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,228,926, June 5, 1917. Date of appl., Apr. 7, 1917.

AN acridine dyestuff alkylated at the acridine nitrogen is treated with a soluble cadmium salt in presence of a solvent. The cadmium compound of 2,7-dimethyl-3,6-diaminoacridine methylated at the acridine nitrogen is specially claimed.—F.W.A.

Silver compound of the acridine series [disinfectant] and process of making same. U.S. Pat. 1,227,624. See XIXB.

Manufacture of urcas and thiourcas of the naphthalene series. Eng. Pat. 20,192. See XX.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wood; Chemistry of —. I. Methods and results of analysis of some American species.

II. Discussion of methods and results. A. W. Schorger. J. Ind. Eng. Chem., 1917, 9, 556—566.

THE following mean results were obtained in the analysis of seven kinds of American wood, four samples of each being taken:—

The water-soluble portion of the western larch consisted largely of a galactan, apparently $(C_6H_{10}O_5)_{50}$, which yielded only galactose on hydrolysis. Wood cellulose probably consists of definite compounds of hexosans with varying proportions of pentosans. In this paper cellulose is defined as the residue left after alternate treatment with chlorine and sodium sulphite up to the point where the chlorine-sulphite colour reaction ceases. Hard woods may be sharply differentiated from conifers by the pentosan content of the cellulose. Thus the amount of pentosans in the cellulose from conifer woods varied from 5 to 10%, and in that from hard woods from 24 to 28%. Douglas fir contained the largest amount of methylpentosans (42% of the total pentosans present). In general, conifers contain more methylpentosans than hard woods. Conifer wood offers much more resistance than the wood of broad-leaved trees to the action of chlorine. The following numbers of chlorinations were required to obtain cellulose free from lignin:—Douglas fir, 4 to 5; white spruce, 4 to 5; long leaf pine, 4; western larch, 5; yellow birch, 2 to 3; basswood, 2; and sugar maple, 2 to 3. In experiments to determine the effect of alkali on the yield of cellulose the following results were obtained with basswood, by two chlorinations of 30 mins. each.

Preliminary treatment.	Cellulose, %
Extracted with alcohol-benzene	62.92
Digested with 50 c.c. of 1% NaOH for 30 mins. in water-bath	59.78
Digested with 100 c.c. of 1% NaOH for 60 mins. in water-bath	58.25

The effect of the preliminary digestion with alkali in reducing the time of chlorination required to remove the lignin is considerable in the case of hard woods, but is less evident in the case of conifer woods. Digestion with alkali followed by acid, however, lowers the yield of cellulose from conifer wood (e.g., from 62.90 to 55.12%). The addition of alkali to the sodium sulphite solution in the removal of the lignin also reduces the yield of cellulose (e.g., by 5.69% after four treatments). The substitution of 2% sodium bisulphite solution for 2% sodium sulphite solution caused a pronounced reduction in the rate of removal of lignin from spruce wood, and the cellulose was pale yellow instead of dark greyish yellow. To render the method efficient it is essential that the liquid should be slightly alkaline. The amount of lignin removed is almost directly proportional to the rate at which the chlorine is introduced. For example, in the case of yellow birch wood the loss in weight was 15.31% when the chlorine bubbles were 44 to 45 per min., and 26.11% when they were 120 to 122 per min. It is advantageous to use a rapid stream of chlorine during

the first chlorination, but in subsequent chlorinations the rate should not exceed about 10 bubbles per min. The accuracy of the method depends upon the observance of exact details of procedure, and results obtained by different chemists using the same method may be regarded as satisfactory if they agree within 1%. The cellulose calculated upon the weight of wood free from substances soluble in ether and hot water is fairly uniform for different species. For example on this basis the amounts of cellulose in the conifer woods ranged from 63.79 to 67.20%, and in the hard woods from 63.43 to 64.97%. Exceptionally results considerably higher or lower than these figures are obtained. The strength of the sulphuric acid used in the acid hydrolysis has considerable influence on the yield of volatile acids. For example, yellow birch wood hydrolysed with 2.5% sulphuric acid yielded 3.99% of volatile acid, as compared with 4.53% when hydrolysed with 10% acid. Small amounts of free or loosely combined formic and acetic acids are present in certain woods, such as *guiso*, a Philippine wood, which has a corrosive action on metal, due to the presence of about 0.2% of acetic acid. The yields of methyl alcohol obtained by destructive distillation are much lower than would be expected from the methoxy values, as is shown by the following results:—

	Birch.	Maple.	Western Birch.
Methyl alcohol %	1.53	1.94	0.65
Methoxy group %	6.07	7.25	4.95

Sulphite-cellulose manufacture: Constitution and stability of the various lyes used in — and their specific action in the digestion process. I. T. Marusawa. Kogyo-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 253—301.

The first stage of the ionisation of sulphurous acid ($\text{H}_2\text{SO}_3 \rightleftharpoons \text{H}^+ + \text{HSO}_3^-$) proceeds approximately in accordance with Ostwald's dilution law provided the concentration is not less than 0.05 gm.-mol. per litre, but the greater the dilution the more the acid behaves as a strong electrolyte. For concentrations between 0.01 and 0.8 gm.-mol. per litre, the ionisation constant, $K_1 = \frac{[\text{H}^+][\text{HSO}_3^-]}{[\text{H}_2\text{SO}_3]}$, is 1.62×10^{-2} — 1.96×10^{-2} at 18° C. At equal concentrations the degree of ionisation of sodium, potassium, and ammonium bisulphites is about the same. The ionisation constant of the second stage of the ionisation of sulphurous acid, $K_2 = \frac{[\text{H}^+][\text{SO}_3^{2-}]}{[\text{HSO}_3^-]}$, was estimated as 3.42×10^{-6} at 18° C. from measurements of the conductivity of potassium bisulphite solutions of concentrations between 0.0025 and 0.005 gm.-mol. per litre, and as 3.18×10^{-6} from colorimetric determination of the hydrogen ion concentration of potassium bisulphite solutions. For concentrations between 0.01 and 1 gm.-equivalent per litre, the equivalent conductivity of magnesium bisulphite at infinite dilution was found to be 88.2 at 18° C., and the degree of ionisation corresponds with the square of the value for potassium bisulphite for concentrations not exceeding 0.03. The solubility of normal magnesium sulphite is 5.01×10^{-2} gm.-mol. per litre at 18° C., and that of calcium sulphite 7.91×10^{-4} gm.-mol. per litre; the latter value differs considerably from the value hitherto accepted. Investigation of the equilibria in the systems, $\text{MgSO}_3 \cdot 6\text{H}_2\text{O} + \text{H}_2\text{SO}_3$ aq. and $\text{CaSO}_3 \cdot 2\text{H}_2\text{O} + \text{H}_2\text{SO}_3$ aq., showed: (1) that for concentrations between 0.02 and 0.5 gm.-mol. Ca per litre, it is impossible to prepare a solution,

saturated with $\text{CaSO}_3 \cdot 2\text{H}_2\text{O}$, of composition corresponding to either $x\text{CaSO}_3 + y\text{Ca}(\text{HSO}_3)_2$ or $x\text{Ca}(\text{HSO}_3)_2$; and (2) that the view that sulphite-cellulose digestion liquors have the composition $x\text{MSO}_3 + y\text{H}_2\text{SO}_3$, is incorrect.

Oxycellulose: Determination of —. G. Kita. Kogyo-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 138—141.

The method of estimating oxycellulose suggested by Nishida, consisting in treatment with a known quantity of Methylene Blue solution and then titrating the excess of dyestuff, not fixed by the oxycellulose, with titanium chloride, is not trustworthy, because the quantity of dyestuff fixed is influenced by the degree of subdivision of the substance under examination and by other factors, and there is no proportionality between the quantity of oxycellulose and that of Methylene Blue absorbed. Though it may be conveniently used in certain special cases, this method is not applicable in the same way as Schwalbe's copper value for the determination of the damage caused by various treatments of cellulose.

Printed paper: Microscopical examination of —. M. Yano. Kogyo-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 219—233.

VARIOUS kinds of paper were printed with an ink prepared by grinding lampblack with "medium" varnish coloured intensely scarlet with Naphthylamine Bordeaux, and the penetration of the coloured varnish was traced by microscopical examination of thin sections of the paper. The penetration varies with the fineness of the paper fibres; in wood pulp papers the varnish easily penetrates to the back side of the paper. If the printed paper is dried at too high a temperature the varnish penetrates quickly and the pigment separates on the surface and is easily rubbed off the drying temperature should not exceed 50° C. Drying may be carried out above 50° C., however if manganese borate be added to the printing ink. Rosin size, though effective in preventing penetration of writing ink in writing papers, does not prevent the penetration of printing ink varnish; indeed the varnish penetrates a paper containing 20% of rosin size more readily than it does unsized paper. Gelatin sizing prevents the penetration of the varnish and renders the paper unsuitable for printing. An excessive quantity of loading material must be avoided, otherwise the pores of the paper are filled and the penetration of the varnish prevented.

Fibrous materials: Separating impurities from waste —. Naamlooze Vennootschap Nec Cellulose Maatschappij, Rotterdam. Eng. Pat. 105,055, May 2, 1916. (Appl. No. 6270 of 1916 Under Int. Conv., Mar. 23, 1916. Addition to Eng. Pat. 21,057 of 1912 (this J., 1913, 1104).)

In cleansing waste fibrous materials by means of emulsifying and separating machines in conjunction with two immiscible liquids, e.g., a liquid hydrocarbon and water, a stable foam is produced on the surface of the heavier or of the lighter liquid in such a manner that the impurities are collected in the foam and thus separated from the fibrous material. For producing a stable foam, the lighter liquid may be replaced by a combination of a solid or semi-solid fatty material, such as vaseline or animal or vegetable fats, and substance, such as soap, which is capable of producing foam. The soap may be utilised as detergent in the preliminary treatment of the

material and as a foam producer in the later treatment; the quantity of soap may amount to 0.01 % of the weight of the fibrous material, and the quantity of fatty substance employed as a foam-tabiliser may amount to 0.02 %.—J. F. B.

Textile fabrics and other materials; Apparatus for impregnating or treating—. J. D. Taylor, London, and F. Shaw and Co., Ltd., Manchester. Eng. Pat. 106,805, Mar. 6, 1917. (Appl. No. 3326 of 1917.)

THE apparatus consists of a closed interconnected system of an impregnating chamber, a drying chamber, a condenser, and a vacuum pump. The impregnating chamber contains two spindles, an impregnating box connected with a supply of the solution, a scraper, and guide rolls. The horizontal drying chamber contains steam-chests or plates and guide rolls for leading the fabric in proximity to the heating surface. The roll of fabric is placed on the upper spindle in the impregnating chamber and the chamber closed; the fabric is led by tapes through the drying chamber and back again and subjected to heat and vacuum; it arrives again in the impregnating chamber dry and exhausted of air. Solution is admitted to the box and the fabric passes through the solution and is wound up on the lower spindle. The direction of the machine is reversed, the fabric is re-impregnated with solution, scraped, passed through the drying chamber, and re-wound on the upper spindle, while the volatile solvent is recovered in the condenser.—J. F. B.

Solvents; Apparatus for recovering—[from coated fabrics]. J. Lynah, Newburgh, N.Y., Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,228,225, May 29, 1917. Date of appl., Oct. 16, 1912.

THE apparatus comprises a feeding chamber for a coating material, an evaporating chamber, means for supporting a coated web therein, a vapour-tight cover loosely supported over the feeding and evaporating chambers, with a liquid seal and an air pipe connected to the cover.—J. F. B.

Rubber; Process of impregnating fabrics with—. I. S. McGiehan, New York. U.S. Pat. 1,228,458, June 5, 1917. Date of appl., Dec. 17, 1915.

THE fabric is passed through a rubber solution so that it becomes thoroughly impregnated; it is then heated, and a coating of rubber is applied to the surface of the fabric; the coating is levelled by flexible scraping devices, and the fabric is finally passed between rollers having yielding surfaces so as to secure density and homogeneity.—J. F. B.

Fibrous materials; Machines and method for waterproofing—. A. O. Tate, Montreal, Canada, Assignor to Tate Electrolytic Waterproofing Co., Inc., New York. U.S. Pats. (A) 1,228,986, (B) 1,228,987, and (C) 1,228,988, June 5, 1917. Dates of appl., (A) Mar. 19, 1915, (B) and (C) Oct. 27, 1916.

(A) THE machine comprises pairs of electrodes of relatively large contacting surface area, connected with means for spraying or moistening the material with one or more electrolytic agents as it passes between the electrodes, together with source of electrical energy and connections for varying the direction of current flow through the successive pairs of electrodes. (B) The material impregnated with a solution of sodium palmitate and moistened with aluminium acetate to precipitate aluminium hydroxide and palmitate; is simultaneously subjected to the action of an electric current between aluminium electrodes to produce an excess of aluminium hydroxide and to drive the same into the fibres of the fabric.

(C) The machine comprises means for impregnating the fabric with a saponaceous solution and for pressing the solution into the interstices of the material. Spraying devices are provided to wet the material with a second reagent, in conjunction with means for conveying the fabric between a pair of roller electrodes, one of which is covered with an absorbent pad, the sprays being so directed that a precipitate is formed by the interaction of the two reagents simultaneously with the action of the electric current upon the material.

—J. F. B.

Broom; Manufacture of a textile fibre from—. E. K. Zeise-Gött, Freiburg, and R. Sütterlin, Mannheim-Neckarau. Ger. Pat. 297,138, Jan. 13, 1916.

BROOM is steamed and crushed as hot as possible, then boiled with sodium carbonate, hydro-extracted, dried, and passed through a breaking machine to eliminate the wood.—J. F. B.

Osier bark; Manufacture of yarns, particularly fine yarns, from—. T. Schiefner, Dresden. Ger. Pat. 297,569, Mar. 22, 1916.

THE bark is subjected to the usual boiling process and then to a washing process with a jolting or swirling motion. This motion agitates the material to and fro in the direction of the length of the fibres and facilitates complete separation of the spinning fibres from the bast tissues and epidermis.—J. F. B.

Plastic compositions; Process of making—. Process of making acetylcellulose plastic compounds. W. G. Lindsay, Caldwell, N.J., Assignor to The Celluloid Co., New York. U.S. Pats. (A) 1,229,485 and (B) 1,229,486, June 12, 1917. Date of appl., July 10, 1915.

(A) A PLASTIC material is made by gelatinising acetylcellulose (100 parts) with chloroform (100 parts) containing 10–20 parts of methyl or ethyl alcohol, adding an alkylated aromatic sulphonamide which is a solvent for acetylcellulose in the presence of chloroform and alcohol, allowing the excess of volatile solvent to evaporate, and manipulating the product. (B) A plastic material is made by gelatinising acetylcellulose with trichloroethylene and methyl alcohol in about equal proportions, adding a solid substance which is a solvent for acetylcellulose in the presence of trichloroethylene and methyl alcohol, allowing the excess of volatile solvent to evaporate, and manipulating the product.—F. Sp.

Acetyl cellulose; Solvent for—. W. G. Lindsay, Caldwell, N.J., Assignor to The Celluloid Co., New York. U.S. Pat. 1,229,487, June 12, 1917. Date of appl., June 6, 1916.

A MIXTURE of an arylacetamide (e.g., tetrachloroethylacetanilide), chloroform, and methyl or ethyl alcohol, is a solvent for acetylcellulose.—F. Sp.

Cellulose for fine, particularly photographic, papers; Process of treatment of—. O. Röhm, Darmstadt. Ger. Pat. 297,324, Nov. 14, 1915.

CELLULOSE previously boiled with water, with or without the addition of alkali, is treated with pancreatic or similar enzymes, with or without the addition of sodium carbonate or other alkaline salts. Wood cellulose contains up to 15% of impurities which are removed by this treatment and the cellulose is thereby rendered more suitable for use in photographic papers.—J. F. B.

Paper; Method of incorporating filling material in—. G. W. Miles, Belmont, Mass., Assignor to Ross Chemical Co., Boston, Mass. U.S. Pat. 1,228,580, June 5, 1917. Date of appl., Mar. 11, 1915.

THE fibre in the beater is mixed with an emulsion

of a waxy material, e.g., paraffin wax, containing a proportion of filler in excess of that which could be incorporated with the fibre in the absence of the emulsion.—J. F. B.

Paper; Manufacture of an opaque, non-stretching, water- and gas-proof—. G. H. C. Sachsenröder, Barmen-Unterbarmen. Ger. Pat. 297,515. June 29, 1915.

ABSORBENT paper is treated with cold sulphuric acid at a density of about 52 B. (sp. gr. F52), then washed, and dried. Several layers of such paper are pressed together between rolls after the webs have passed through the bath, and the product is used as a packing material for joints.—J. F. B.

Sulphite-cellulose waste liquor; Process for utilising—. M. Müller, Finkenwalde. Ger. Pat. 297,374. July 2, 1916.

SODIUM bisulphate is roasted in a furnace under reducing conditions with waste liquor from the digestion of sulphite pulp. The free sulphuric acid of the bisulphate is reduced to sulphurous acid which may be employed for the preparation of fresh sulphite liquor.—J. F. B.

Sulphite- and sulphate-cellulose waste liquors; Process for the evaporation of—. E. Mürbe, Grlitz. Ger. Pat. 297,440, Oct. 11, 1914. Addition to Ger. Pat. 293,394 (this J., 1916, 1106).

THE waste liquors are sprayed in contact with furnace gases with simultaneous admission of air, the temperature of the mixing chamber and of the saturated flue-gases being maintained above the boiling point of water, preferably at 110°–120° C. A fan is arranged for the introduction of air into the lower portion of the mixing chamber and a drying arrangement is provided beneath the mixing chamber to receive the aqueous lignin liquor discharged from the bottom of the mixing chamber.—J. F. B.

Artificial silk and other threads; Apparatus for treating—. M. Linfoot, Braintree, Assignor to Courtaulds, Ltd., London. U.S. Pat. 1,229,101, June 5, 1917. Date of appl., Aug. 10, 1915.

SEE Eng. Pat. 18,556 of 1914; this J., 1915, 957.

Determination of free chlorine in solutions of hypochlorites. Dienert and Wandenbulke. See VII.

PATENTS.

Textile materials; Treating—with dye and other liquors. W. C. Singleton, Manchester. Eng. Pat. 106,897, July 26, 1916. (Appl. No. 10,515 of 1916.)

AN apparatus for dyeing or treating cotton, wool, or other fibrous material, is provided with an inner cage fitted with a false bottom of grids or perforated plates hinged or pivoted at the ends or sides to open to allow the material to be easily discharged. The outer tank is provided with guides for the cage, and hinged, pivoted, or removable baffle-plates direct the liquor between the walls of the tank and the inner cage.—F. W. A.

Dyeing-machine. H. Higgs, Assignor to Klauder-Weldon Dyeing Machine Co., Amsterdam, N.Y. U.S. Pat. 1,229,612, June 12, 1917. Date of appl., Mar. 9, 1914.

A ROTARY cage consisting of a number of compartments to contain the material to be dyed, which are bounded by peripheral walls and longitudinal concavo-convex perforated walls, is placed in a vat so that the perforated walls are continuously submerged during its rotation.—F. W. A.

Dyeing, washing, and the like; Machine for—. J. H. Milnes, Huddersfield. U.S. Pat. 1,230,198, June 19, 1917. Date of appl., Dec. 7, 1916.

SEE Eng. Pat. 16,199 of 1915; this J., 1916, 1216.

Textile and other materials; Process for producing colours on—. J. Chester, Saltaire. U.S. Pat. 1,231,492, June 26, 1917. Date of appl., Nov. 24, 1915.

SEE Eng. Pat. 23,214 of 1914; this J., 1915, 1040.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Hypochlorites; Determination of free chlorine in solutions of—. F. Dienert and P. Wandenbulke. Comptes rend., 1917, 165, 28–29.

INCREASING quantities of ammonium sulphate were added to a series of solutions in which the iodine liberated from potassium iodide by hypochlorite was titrated by N/35.5 arsenious acid. It was found that by taking at least 150 parts of ammonium sulphate to one part of available chlorine present, the formation of iodate is prevented and the chlorine can be estimated in alkaline solution by arsenious acid. It is necessary to use dilute solutions of hypochlorite, as in concentrated solutions ammonia is partly decomposed, giving nitrogen and hydrochloric acid with consequent loss of free chlorine. The influence of the ammonium sulphate in the reaction is due to the formation of chloramine, and the sulphate can be replaced by chloride.—J. N. P.

Iodine; Action of—on alkalis. J. Bougault. Comptes rend., 1917, 164, 949–951.

WHEN iodine is added to caustic soda, the oxidising potential, as expressed in hypoiodite, falls off very rapidly, and in a few minutes almost the whole of the iodine is in the state of iodate. Similar reactions take place, though more slowly, with iodine and sodium carbonate, but with sodium bicarbonate neither the formation of iodate nor of hypoiodite is observed. On adding, however, sodium thiosulphate to the mixture, the amount required to decolorise the liquid, and the production of sodium bisulphate, appear to indicate the formation under these conditions of sodium bicarbonate. These mixtures of iodine with caustic soda, sodium carbonate, and bicarbonate, are recommended as oxidising media of variable intensity.—B. N.

Calcium oxide or hydroxide in the presence of some aluminates or silicates; Titration of —. W. E. Emley. Trans. Amer. Ceram. Soc., 1915, 17, 720—726.

By means of the following method, calcium oxide or hydroxide may readily be determined in the presence of mono- or di-calcium silicates, mono- or 5:3-calcium aluminates, calcium carbonate, calcium sulphate, and (with a little more skill in recognising the end-point) tricalcium silicate and magnesia. With tricalcium aluminate special precautions must be taken to ensure the absence of water, e.g., by re-distilling the alcohol over quicklime immediately before using. The finely powdered sample, in amount sufficient to give 0.1 gm. free lime, is added to 2 c.c. of glycerin and 10 c.c. of alcohol, then 5 drops of phenolphthalein is added, and the mixture is heated to boiling and kept nearly boiling whilst titrating with N/5 alcoholic ammonium acetate. The end-point is reached when the pink colour is discharged and does not return after boiling for one minute. The ammonium acetate may be standardised against pure calcium oxide. The method appears to be satisfactory with white lime-sand bricks, but not with coloured ones or with Portland cement, as the colour of the material obscures the end-point of the reaction.—A. B. S.

Potassium metasilicate-silica-water; The ternary system —. G. W. Morey and C. N. Fenner. J. Amer. Chem. Soc., 1917, 39, 1173—1228.

The equilibrium relations of this system have been studied over the range 200°—1000° C., with a view to investigating the conditions under which crystallisation of rock magmas may have occurred, here volatile as well as non-volatile components are probably been present. The method generally employed was to measure at various constant temperatures the change in the water content with the variation of the $\text{SiO}_2/\text{K}_2\text{O}$ ratio in the saturated solution. The mixture taken was heated in a suitably designed bomb (J. Amer. Chem. Soc., 1914, 36, 215) until equilibrium might be supposed to be attained, and then by rapidly cooling the bomb the equilibrium product was "frozen." The product, when suitably cooled, is in the same condition as regards crystalline or glassy character and chemical composition as when hot, and enables conclusions to be drawn as to the equilibrium conditions obtaining at the high temperature. The examination was both chemical and microscopical. The following compounds were identified in the melts: $\text{K}_2\text{O} \cdot 4\text{SiO}_2 \cdot \text{H}_2\text{O}$, $\text{K}_2\text{O} \cdot 2\text{SiO}_2 \cdot 0.2\text{SiO}_2 \cdot \text{H}_2\text{O}$, $\text{K}_2\text{O} \cdot \text{SiO}_2$, $\text{K}_2\text{O} \cdot \text{SiO}_2 \cdot 0.5\text{H}_2\text{O}$, $\text{O} \cdot \text{SiO}_2 \cdot \text{H}_2\text{O}$, and SiO_2 . The space model of the relationships between the various phases equilibrium was constructed.—H. J. H.

amide; Preparation of — from calcium cyanamide. I. Kitawaki and K. Kusano. Kogyo-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 234—252.

The authors have found that for the preparation of cyanide from crude calcium cyanamide, the best yields are obtained under the following conditions. A mixture of 10 parts of crude calcium cyanamide (53.3% CaCN_2), 16—24 parts of calcium chloride (or 7—10 parts of anhydrous calcium carbonate), and 2 parts of charcoal is heated at 900°—950° C. (950°—1000° C. if sodium carbonate is used) for 10 mins., and the fused product is allowed to cool without coming in contact with air. In the authors' experiments the charge was heated in iron crucibles (14 grms. and 4—450 grms. capacity respectively) in an electric resistance furnace, and yields of more than 70% of the theoretical quantity of cyanide were obtained.

Ferric ferrieyanides; Colloidal —. R. Haller. Kolloid Zeits., 1917, 20, 76—81. J. Chem. Soc., 1917, 112, i., 324—325.

By the interaction of aqueous solutions of ferric chloride and potassium ferrieyanide, colloidal ferric ferrieyanide is formed. The freshly formed colloid is highly dispersed, but ultra-microscopic observations show that the particles undergo a gradual process of aggregation, and this leads ultimately to the separation of Prussian green. By the action of sodium hydrosulphite on the brown colloidal solution, a mixture of colloidal Prussian blue and Turnbull's blue is obtained. Further reduction yields colloidal Prussian white. The actual result of the action of potassium ferrieyanide on ferric chloride varies with the concentration of the aqueous solutions. If alcoholic solutions of ferric chloride and potassium ferrieyanide are mixed together, ferric ferrieyanide is obtained in the form of an unstable, gelatinous precipitate.

Bismuth acetate. E. Salkowski. Biochem.-Zeits., 1917, 79, 96—104. J. Chem. Soc., 1917, 112, i., 316.

The acetate was formed by dissolving the finely divided metal in a mixture of acetic acid and hydrogen peroxide, or by dissolving the hydroxide in acetic acid. A crystalline product, $\text{Bi}(\text{C}_2\text{H}_3\text{O}_2)_3$, was obtained, which is unstable and loses acetic acid on keeping in air, and more rapidly in a vacuum. If heated at 125° C., it loses acetic anhydride rapidly and yields bismuthyl acetate: $\text{Bi}(\text{C}_2\text{H}_3\text{O}_2)_3 = \text{BiOC}_2\text{H}_3\text{O}_2 + \text{C}_2\text{H}_6\text{O}_2$. The bismuthyl salt, unlike the salt $\text{Bi}(\text{C}_2\text{H}_3\text{O}_2)_3$, is insoluble in water.

Zirconyl sulphates. E. Chauvenet. Comptes rend., 1917, 164, 946—949.

SULPHATES described previously (this J., 1917, 711) are regarded as derivatives of the radical zirconyl, and the following formulæ are given to them: $\text{ZrOSO}_4 \cdot \text{SO}_3$; ZrOSO_4 ; $3\text{ZrOSO}_4 \cdot \text{ZrO}_2$; $2\text{ZrOSO}_4 \cdot \text{ZrO}_2$; $\text{ZrOSO}_4 \cdot \text{ZrO}_2$; and $5\text{ZrOSO}_4 \cdot \text{ZrO}_2$. The first compound is the acid sulphate, and may be prepared in the dehydrated state or combined with 1 or 4 mols. of water; the second, or neutral sulphate, may be obtained anhydrous, or with 1, 2, or 4 mols. of water; the remainder, or basic sulphates, may be obtained anhydrous or combined with water, the last compound combining with 12 mols., whilst the others combine with 8 mols. of water.—B. N.

Zirconyl; Acid sulphate of —. E. Chauvenet. Comptes rend., 1917, 165, 25—28.

In aqueous solution, zirconyl acid sulphate (see preceding abstract) appears to have the constitution $\left[\text{Zr} \begin{smallmatrix} \text{O} \\ \text{SO}_4 \end{smallmatrix} \right] \text{SO}_4$ and to hydrolyse according to the equation: $4(\text{ZrOSO}_4 \cdot \text{SO}_3) + \text{aq} = 5\text{H}_2\text{SO}_4 + 3\text{ZrOSO}_4 \cdot \text{ZrO}_2$. The curve showing the change of electrical resistance during gradual neutralisation of zirconyl acid sulphate by sodium hydroxide gives bends at the stages corresponding to the formation of zirconyl sulphate, ZrOSO_4 , and again with the formation of the basic sulphate, $\text{ZrOSO}_4 \cdot \text{ZrO}_2$, which is the most stable of these compounds and was found to be slowly formed at 30° C. by the reaction of the basic trisulphate with water. The zirconyl radical has a marked tendency to give compounds of the type $\text{ZrOA} \cdot \text{ZrO}_2$, where A is an acid radical such as Cl , Br , or SO_4 .—J. N. P.

PATENTS.

Sulphuric acid in lead chambers; Production of —. T. C. Oliver, Charlotte, N.C. U.S. Pat. 1,229,316, June 12, 1917. Date of appl., Feb. 7, 1917.

A LEADEN chamber is surrounded and covered by a housing which forms separate air passages extending upwards along the outer surface of the walls of the chamber, and means are provided for allowing a natural or forced draught of air to flow along the air passages.—F. Sp.

Hydrochloric acid; Manufacture of —. A. H. Peter, Assignor to Royal Baking Powder Co., New York. U.S. Pat. 1,229,509, June 12, 1917. Date of appl., Apr. 12, 1912.

HYDROCHLORIC acid is produced by adding to chlorine sufficient water vapour to form a mixture showing practically no green colour against a white background (approximately 3 parts of chlorine to 7 parts of water vapour), and leading the mixture over carbon at a temperature between 100° C. and red heat.—F. Sp.

Drenching a material with a liquid and thereafter draining it therefrom; Process for periodically —. [Preparation of basic lead acetate.] A. T. Eyton, Nelson, B.C. Eng. Pat. 107,115, Sept. 2, 1916. (Appl. No. 12,461 of 1916.)

SEE U.S. Pat. 1,206,685 of 1916; this J., 1917, 75. The process may be applied to the production of basic lead acetate, metallic lead being periodically drenched with a solution of acetic acid and exposed to the air between successive drenchings.

Potassium salts; Process for recovering — from organic carbonaceous materials. F. C. Grimes, Idaho Falls, Idaho. U.S. Pat. 1,227,781, May 29, 1917. Date of appl., Aug. 19, 1916.

ORGANIC carbonaceous material is burnt in an open-top chamber under forced draught, and sulphur, or other material which liberates oxides of sulphur, is added. Potassium chloride in the organic material is thus converted into sulphate.—W. F. F.

Effervescent compound. M. D. Sohn, New York. U.S. Pat. 1,228,252, May 29, 1917. Date of appl., Sept. 9, 1915.

AN effervescing mixture containing sodium pyrosulphate.—W. F. F.

Bodies of extended discontinuously associated solid particles of [magnesium or] calcium carbonate; Method of producing — and the product thereof. W. R. Seigle, Assignor to H. W. Johns-Manville Co., New York. U.S. Pats. (A) 1,228,485 and (B) 1,228,486, June 5, 1917. Dates of appl., June 1, 1915, and June 28, 1916.

(A) A MIXTURE of powdered magnesium carbonate,

asbestos fibre, and cellulose fibre is mixed with a liquid containing an insoluble soap. The liquid is then removed, and the residual solid dried. (B) The magnesium carbonate in (A) is replaced by calcium carbonate, and in a modification, sulphite pulp fibre is substituted for asbestos and cellulose fibre.—W. F. F.

Lead arsenate; Method of making —. E. O. Barstow and J. A. Cavanagh, Assignors to Dow Chemical Co., Midland, Mich. U.S. Pat. 1,228,516, June 5, 1917. Date of appl., Aug. 2, 1916.

LEAD arsenate is produced by reaction between arsenic acid and sublimed lead monoxide in presence of water.—W. F. F.

Aluminium skimmings, screenings, slags, or analogous materials; Method of processing —. [Production of aluminium nitride.] P. R. Hershman, Milwaukee, Wis., Assignor to W. F. Jobbins, Inc., Aurora, Ill. U.S. Pat. 1,229,611, June 12, 1917. Date of appl., Nov. 14, 1912.

ALUMINIUM skimmings, etc., mixed with a reducing agent, such as a liquid hydrocarbon, are heated without access of nitrogen to a temperature (about 1200° C.) at which spontaneous heating would occur with formation of aluminium nitride on exposure to air, and the mixture is then exposed to air.—F. W. A.

Calcium cyanamide; Apparatus for manufacture of —. N. C. Tommasi, Assignor to Elektrizitätswerk Lonza, Basle, Switzerland. U.S. Pat. 1,230,343, June 19, 1917. Date of appl., Jan. 5, 1917. (See Fr. Pat. 476,294 of 1914; this J., 1916, 16.)

A ROTARY furnace is provided with a feeding device for calcium carbide, a discharging device for calcium cyanamide, and means for circulating nitrogen through external heating or cooling devices in order to regulate the temperature.—F. Sp.

Per-salts [perphosphates and perarsenates]; Production of —. S. Aschkenasi, Berlin. Ger. Pat. 296,796, July 26, 1914.

ALKALINE-EARTH peroxides can be dissolved in excess of concentrated phosphoric or arsenic acid forming hydrogen peroxide and the corresponding primary per-salt. The hydrogen peroxide does not decompose, and by evaporation under reduced pressure, with minimum elevation of temperature the primary perphosphate or perarsenate can be obtained. The corresponding alkali salts can be obtained by decomposing the alkaline-earth salt before evaporation with an alkali sulphate.—W. H. P.

Per-salts; Production of anhydrous — or mixtures of per-salts. S. Aschkenasi, Berlin. Ger. Pat. 296,888, Sept. 21, 1915. (See preceding abstract.)

PER-SALTS prepared *in vacuo* can be subsequently dried in air at 100° C., without evolution of oxygen. They soften and again dry giving off an appreciable quantity of water vapour. Drying in this way improves the stability of the per-salts.—W. H. P.

Chlorine and other gases; Compressing —. Società Italiana di Elettrochimica, and L. L. Bianchini Rome. Eng. Pat. 106,722, Aug. 7, 1916. (Appl. No. 11,122 of 1916.)

IS a compressing system for chlorine and the like using sulphuric acid for compressing the gas, strong sulphuric acid from a supply tank passes through a cooling coil to a rotary compressor (in which the gas is also supplied. Additional compressors in series may be used, with a cooling coil between each pair. The compressed gas passes

to a centrifugal diaphragm separator, and the acid passes to one of a pair of similar closed vessels. When full, the acid is diverted to the other vessel, and that in the first vessel is forced back to the supply tank by compressed air. Acid recovered from the centrifugal separator is also returned to the collecting vessels.—W. F. F.

Graphite; Manufacture of artificial — [from waste lyes from cellulose manufacture]. H. Messow, Berlin. Ger. Pat. 297,075, Aug. 8, 1915.

WASTE lyes from the manufacture of cellulose are mixed with oxides of heavy metals, e.g., ferric oxide, and with calcium phosphate, and the mixture is exposed to a high temperature and a very high pressure. The graphite so produced is converted into flake graphite by means of hot rolls.

Hydrogen; Manufacture of —. Badische Anilin und Soda Fabr. Ger. Pat. 297,258, Sept. 11, 1914. Addition to Ger. Pat. 292,615.

CONTACT masses prepared by saturating pumice with a solution of nickel or cobalt chloride and subsequently igniting (see Fr. Pat. 463,114 of 1913; this J., 1914, 313), have not proved satisfactory in the production of hydrogen from carbon monoxide and steam. Good yields of hydrogen are obtained, however, by using contact masses prepared by impregnating suitable materials with relatively small quantities of solutions of nickel salts free from halogens and sulphur.

Sodium chloride; Process for separating — from liquors containing it and sodium nitrate in solution. I. B. Hobsbaum, London, and J. L. Grigioni, Richmond. U.S. Pat. 1,230,162, June 19, 1917. Date of appl., May 20, 1915.

SEE Eng. Pat. 12,474 of 1914; this J., 1915, 715.

Sodium nitrate; Process of recovering — from liquors containing it and sodium chloride in solution. I. B. Hobsbaum, London, and J. L. Grigioni, Richmond. U.S. Pat. 1,230,163, June 19, 1917. Date of appl., May 20, 1915.

VIII.—GLASS; CERAMICS.

Scientific glass-ware; Action of chemical and physical agents on some types of —. J. D. Cauwood, S. English, and W. E. S. Turner. Soc. Glass Technol., July 25, 1917.

THE method employed in the research was to subject Jena glass, five new British resistance glasses, and a few chemical glasses made in allied and neutral countries to the following series of tests:—Action of steam. Action of boiling water. Action of water under a pressure of 10 kilos. per sq. cm. Action of water at 20° C. and at 80° C. Action of N/10 and 2N sodium hydroxide, 2N sodium carbonate solution, 5% ammonium chloride solution, and 2N ammonia solution at 100° C. Action of hydrochloric acid fumes, boiling hydrochloric acid solution, and 2N sulphuric acid at 100° C. Cracking test. In addition each glass was analysed. From the results it was apparent that in every test applied the British glasses compared most favourably with Jena glass, in some of the tests even surpassing it.

Salt-cake and soda-ash in the glass industry. L. Springer. Keram. Rundsch., 1916, 24, 25, 159. J. Soc. Glass Technol., 1917, 1, Abstracts, 4—5.

IN discussing the substitution of other materials, chiefly salt-cake, for soda-ash in glass making, it is pointed out that salt-cake made in lead-lined pans contains only 0.01—0.03% of iron oxide, whereas that made in iron pans contains 0.07—0.13%. Salt-cake made by the Hargreaves process (treating common salt with sulphur dioxide, air, and steam in iron cylinders) is practically free from iron. For glass making salt-cake should not contain more than 0.02% of iron oxide, 1% of free sulphuric acid, 0.5% of undecomposed salt, and 0.5% of calcium sulphate. If the soda ash in a glass batch be replaced by an equivalent quantity of salt-cake (100 parts for 75 parts of soda-ash), and proper precautions be observed, the quality of the glass should be entirely unaffected. In a batch containing salt-cake a reducing agent (coal or anthracite) is necessary, and the lime should preferably be added as limestone, as the carbon dioxide then evolved facilitates the escape of the sulphur dioxide produced from the salt-cake.

Common salt is of little value as a substitute for soda-ash. Alkali metasilicates have also been suggested as substitutes for soda-ash. Their value in practice would depend upon the possibility of obtaining them sufficiently pure and at a low enough price.

It is suggested, as a possible development, that glass might be melted in very large quantities in certain centres and sold to individual manufacturers for re-melting, colouring, and working up into glass articles.

Barium peroxide as a substitute for nitre in glass batches. L. Springer. Sprechsaal, 1916, 49, 18 and 136. J. Soc. Glass Technol., 1917, 1, Abstracts, 3—4.

SOME commercial "saltpetre substitutes" were found to consist chiefly of barium peroxide, one preparation, for example, containing 77.3% of barium peroxide, 13.9% of barium carbonate, and 6.2% of barium oxide. Barium peroxide gives off oxygen when heated to 700—800° C., but to supply a given quantity of free oxygen to a glass batch four times as much barium peroxide would be required as of nitre, and the barium oxide so introduced would affect the quality of the glass, so that in a lead glass the proportion of lead and in a lime-soda glass the proportion of lime would have to be reduced to allow for the barium oxide added. In small quantities barium peroxide has no deleterious effect on glass.

Alumina; Influence of — on the fusibility of glasses. F. Singer. Keram. Rundsch., 1915, 5. J. Soc. Glass Technol., 1917, 1, Abstracts, 16—17.

THE alumina was added in the form of pegmatite, of which two samples were used, containing respectively: SiO₂, 75.95, 93.61; Al₂O₃, 13.01, 3.51; Fe₂O₃, 0.31, 0.20; CaO, 0.36, 0.44; MgO, 0.49, 0.33; (1) alkalis, 9.34; (2) K₂O 1.89; loss on ignition, 0.66, 0.27%. Two lime-soda batches were made up, corresponding to: (1) 0.1 CaO, 0.6 Na₂O, 2.6 SiO₂; (2) 0.5 CaO, 0.5 Na₂O, 2.6 SiO₂. Sufficient of the pegmatite No. 1 was added to give, in successive mixtures, 0.263, 0.2, 0.15, 0.10, and 0.05 mol. Al₂O₃, and batches were melted at 950°, 1150°, 1250°, and 1420° C. respectively. At 1420° C. melting was too rapid to observe the effect of the alumina. The batches with the larger proportions of alumina were less fusible than the alumina-free batches, but at 1150° C. mixtures with the smaller proportions of alumina (0.15, 0.10, and 0.05 Al₂O₃) were distinctly more fusible than the alumina-free mixtures. In another series of experiments it was found that the influence of alumina, in moderate quantities, on the melting point, depends on the relative proportions of lime

and soda and, in some cases, on the silica. Thus, with lime and soda in the proportion 0.4 CaO : 0.6 Na₂O, there was little difference between the melting points of alumina-containing and alumina-free batches, and the same was true for batches containing lime and soda in the proportion 0.5 CaO : 0.5 Na₂O with 2.5–2.75 SiO₂, but when the silica was increased to 3.0 SiO₂, alumina had a favourable effect in the case of the 0.5 CaO : 0.5 Na₂O batches. With lime and soda in the proportion 0.6 CaO : 0.4 Na₂O, alumina had a beneficial effect whether the proportion of silica was 2.5 SiO₂ or 3 SiO₂. These results show that when alumina is present, in addition to its beneficial effect on the properties of the glass, the proportions of lime and of silica may be increased and the alkali decreased. Alumina was found to diminish the tendency to devitrification.

Glass of the type RO, 3SiO₂; Variation in soda, lime, and magnesia content of a— C. C. Rand. Trans. Amer. Ceram. Soc., 1915, 17, 236–239.

Mixtures of magnesium carbonate, whiting, and soda ash in different proportions were prepared to correspond to a triaxial diagram the apices of which represent MgO.3SiO₂, CaO.3SiO₂, and Na₂O.3SiO₂ respectively, the increments being 1/15 equiv. RO. Each batch of 500 grms. was ground in a ball mill, then introduced into a crucible previously heated to 1000° C. The batch was melted, kept molten until free from air bubbles, and then poured out to an iron plate and rolled into a sheet 1/8 in. thick. The replacement of lime by magnesia reduced the amount of devitrification in the glass. In no case did devitrification occur in the lime-free glasses. The mixtures which contained less than 1/15 equiv. Na₂O.3SiO₂ were too viscous to pour. Most of those which contained less than 1/6 equiv. Na₂O.3SiO₂ devitrified after pouring. Many of the mixtures containing less than 1/3 equiv. Na₂O.3SiO₂ and 2/5 to 2/3 equiv. CaO.3SiO₂ devitrified after being heated to 800° C. in 6 hrs. and cooled in about 20 hrs. All the mixtures which contained more than 2/3 equiv. Na₂O.3SiO₂ produced glasses which were too soluble to be useful.—A. B. S.

"Seeds" in glass : Cause and differentiation of— R. L. Frink. Trans. Amer. Ceram. Soc., 1915, 17, 793–802.

"SEEDS" in glass are seen under the microscope to consist of minute blisters, which contain carbon monoxide or dioxide. The following varieties have been distinguished: (1) Seeds largely due to overworking the furnaces. (2) Seeds due to smoke or oil-vapour introduced when the pontil is inserted in the molten glass; these are bounded by a yellow zone and usually contain minute particles of ash or soot; they are not well distributed through the glass, but occur in local areas. (3) Seeds containing sulphur dioxide or volatilised sodium chloride, the crystals of the latter being recognisable under the microscope. (4) Seeds due to the production of gas formed on re-melting a devitrified cullet. (5) Seeds due to arsenic and containing crystals of arsenic trioxide. (6) Seeds caused by the occlusion of air, as when a jet of air plays on a crevice in the pot. (7) Seeds produced by incomplete melting of the glass and characteristically spherical. The author suggests that formation of seed may be prevented in most cases by not exceeding the proper output of the furnace and by studying its operation so as to secure homogeneity and freedom from gaseous occlusions.—A. B. S.

Glass; Red staining of—by means of copper compounds. L. Springer. Sprechsaal, 1916, 49, 50, 56, 61, 75, 80, 88. J. Soc. Glass Technol., 1917, 1, Abstracts. 18–20.

In the experiments described, small beakers were

used, made of a glass of the composition: SiO₂, 72; CaO, 9; Na₂O, 5.5; K₂O, 12.0%, corresponding to a batch mixture composed of: sand, 100; calcium carbonate, 22; sodium carbonate, 13, and potassium carbonate, 24 parts. The trial pieces were painted over with the colouring paste and fired three times in a muffle kiln. The first firing was under oxidising conditions, and part of the copper compound in the colouring paste was burnt into the glass, producing a yellowish- or bluish-green colour. After cooling, the residual paste was washed off, and the glass then fired under strongly reducing conditions, coal or lignite being placed in the muffle with the glass, and the air supply cut down as low as possible. The copper compounds in the glass were thus reduced, giving rise to a fine ruby-red colour. The trial pieces were subsequently fired a third time to burn away carbon, deposited on the glass during the second firing. The most successful colouring mixtures were:—(1) 100 parts of "yellow earth" (ochre), and 200 parts of crystallised copper sulphate, the copper being precipitated by caustic soda, and the product freed from sulphuric acid by calcining and from sodium salts and soluble sulphates by washing. (2) 100 parts of ochre and 66 parts of copper oxide ground together. (3) 100 parts of ochre and 200 parts of copper sulphate, calcined thoroughly to remove sulphuric acid. Pastes containing the copper as sulphate "strike" the glass at a much lower temperature than oxide pastes, but have an action on the glass itself, and the resulting ruby colour is irregular and inclined to be matt and streaky. Oxide pastes require a considerably higher temperature in the first firing, but the ruby tints obtained after reduction are much finer. To obtain a good ruby glass by this method, the colouring paste must be as finely ground and as intimately mixed as possible, and it must be applied evenly to the glass. The temperature in the first firing at which the best results are obtained must be ascertained for each particular kind of glass; it cannot be varied many degrees without unsatisfactory results. For the glass mentioned above, a temperature of about 600° C. was found suitable.

Glass; Silvering of— A. Silverman and P. D. Neckerman. Trans. Amer. Ceram. Soc., 1915, 17, 505–519.

A BRIEF historical summary with bibliography. The authors state that Brashear's process (in which silver nitrate is reduced by a mixture of loaf sugar, nitric acid, alcohol, and water) is the only one in which the subject is approached quantitatively. They have undertaken an extensive investigation on the precipitation of metals in the form of mirrors, and in the present paper describe some preliminary qualitative experiments.—A. B. S.

Kaolins : A comparison of some—in respect of size of grain. C. F. Binns. Trans. Amer. Ceram. Soc., 1915, 17, 356–371.

SEVERAL English, American, and German clays were deflocculated and then treated in a modified Schultze's elutriator consisting of a series of five cylinders of 5.0, 7.5, 13.5, 21.5, and 30 cm. diameter, respectively, through which a stream of water flows in succession with an upward velocity of 1.5, 0.7, 0.18, 0.08, and 0.04 mm. per sec., the finest particles being carried away by the water passing out of the last cylinder. With most kaolins, the amount left behind by a flow of 0.7 mm. per sec. is negligible. The third vessel, with a flow of 0.18 mm. per sec., is of the greatest importance in expressing the grain of a clay; the percentage of material retained in it varies from less than 5 to more than 25%. In the succeeding cylinder the variation with different clays is much less. English, German, and Georgian (U.S.A.) kaolins are very similar in grain. Some of the second-

class English china clays clearly show a large content of coarse grains, but this is most marked with North Carolina (U.S.A.) kaolins; these are particularly difficult to deflocculate.—A. B. S.

Clays; Use of deflocculating agents in washing—and the effect of the process on the colour. G. H. Brown and W. L. Howat. Trans. Amer. Ceram. Soc., 1915, 17, 81—90.

The addition of 0.05—0.25% of caustic soda to a clay slip effects the deflocculation of the clay and keeps it in suspension, whilst silica and other impurities settle out. The addition of aluminium chloride re-flocculates the clay. The colour of English china clays is not altered by this treatment, but that of several American clays is greatly improved. The treated clays have a lesser drying shrinkage and a greater burning shrinkage than the raw clays.—A. B. S.

Cracking clays; Effect of lime on certain—. N. B. Davis. Trans. Amer. Ceram. Soc., 1915, 17, 497—504.

CRACKING clays are of two types according as the gelatinous matter causing the excessive plasticity and shrinkage is of inorganic or organic nature. Clays which cracked when made into a paste with water and then allowed to dry, were mixed (dry) with 3, 4, 6, or 12% of lime and then tempered in the usual manner. The proportion of lime required varied with the nature of the clay, but in each case a sufficient quantity of lime prevented cracking. The cracking is attributed to the very finely divided colloidal gelatinous matter, which has a great affinity for water. On mixing the dry clay with lime, and then adding water, the conditions are favourable for the immediate formation of calcium silicates or for the destruction of the organic colloids by the lime. It is impossible to mix a wet plastic clay with lime; the clay should be dried, ground so that it will pass a 15-mesh sieve, mixed (dry) with the lime, and then tempered.

In the discussion, H. F. Staley pointed out that preheating the clay before use would, in most cases, serve the same purpose, and be cheaper and free from the objections to lime. He suggested that the addition of common salt is preferable to that of lime.—A. B. S.

Drying behaviour of some [American] clays; Effect of salts on—. H. F. Staley. Trans. Amer. Ceram. Soc., 1915, 17, 697—719.

THE addition of anhydrous sodium carbonate decreases the rate of drying, increases the tendency to crack, and lengthens the range of vitrification of the clays studied. Sodium chloride decreases the rate of drying and cracking, produces better coloured ware, and has a beneficial effect on vitrification, but usually increases shrinkage. The addition of $\frac{1}{4}$ to 2% of salt renders many tender Iowa clays workable. The addition of magnesium and calcium sulphates to clays is not recommended. The reduction of cracking by the addition of sodium chloride is due to its flocculating effect on the clay and the resulting production of a structure favourable to capillary action.

—A. B. S.

Castling [pottery]; Notes on—. A. V. Bleininger and M. R. Hornung. Trans. Amer. Ceram. Soc., 1915, 17, 330—355.

THE liquefying action of various alkaline salts on clay is due to their hydrolysis and to the action of the resultant negatively charged OH ions which repel the similarly charged clay particles and increase the state of dispersion in the system, breaking the larger particles into smaller ones. If there is an excessive concentration of OH ions a "stiffening" of the mass will occur and the

alkalinity will decrease. Organic colloids act similarly to alkaline salts, but also protect the particles and make the liquid less sensitive to the action of flocculating agents. The presence of salts such as sulphates or chlorides of calcium, magnesium, or aluminium in a clay may render the maximum liquefaction of the clay impossible. The viscosity of a clay slip is an extremely important factor in governing the rate of sedimentation; it is best determined by means of a simple efflux viscometer of the Marriotte flask type, no kinetic or temperature corrections being necessary in ordinary work. As a large volume of air is absorbed by clay slips, they must be thoroughly stirred or even subjected to a vacuum before determining their viscosity. The effect of this entrapped air is specially marked with some kaolins. Sodium silicate reduces the viscosity of a clay more effectively than sodium carbonate. Kaolins differ greatly in regard to the change effected in their viscosity by various reagents. Absorption of the reagents also has an important effect on the viscosity; sodium hydroxide is absorbed to a far greater extent than sodium carbonate. The addition of alkali sometimes increases the tensile strength of cast bodies. Mixtures containing a low concentration of alkali are more liable to change their viscosity with time than those of greater concentration. The viscosity of a mixture of several clays may differ from that which would be anticipated, on account of reactions which occur among the impurities present in the clays. Thus a mixture of 45% English china clay and 55% Georgia kaolin requires $2\frac{1}{2}$ times as long to flow out of the viscometer as would be expected from the viscosity of each of these clays taken separately. The changes effected by the addition of various amounts of different reagents to American kaolins and ball clays and to mixtures of these in various proportions are shown in 15 graphs.—A. B. S.

Plaster [pottery] moulds; Notes on the manufacture of—. G. A. Williams. Trans. Amer. Ceram. Soc., 1915, 17, 322—329.

THE breakage of moulds can be reduced by care in handling and drying the moulds and by mixing the plaster in such a manner as to produce the strongest possible mould. Moulds which are heated above 110° C. soon crumble. A very thin clay slip may crack the moulds by the internal expansion of the plaster whilst absorbing water. A mixture of plaster and water was poured into a tin pan, 14 in. × 9 in., and the rate of setting was noted by standing a thermometer in it and noting the time taken to reach the maximum temperature. The rise in temperature varied from 15° to 22°, and the time of setting from 11 to 54 mins. according to the accelerator added. The set plaster was sawn into blocks and slabs which were planed to bars (1) $3\frac{3}{4}$ in. × $\frac{13}{16}$ in. × $\frac{15}{16}$ in., (2) 6 in. × 3 in. × $\frac{15}{16}$ in. These bars were kept at 85° C. for 48 hrs. and then tested. The modulus of rupture ($S = \frac{1.5 pl}{bd^2}$ where S =modulus, p =load, l =distance

between supports, b =breadth and d =thickness of bar) varied from 230 to 705. The relative hardness was determined by applying a jet of water (delivery 3500 c.c. per min. at a pressure of 36 in. of mercury) to the plaster, the jet being 10 in. from the face of the slab. The time taken to wear a hole through the plaster varied from 5.5 to 28 mins. The weight of water absorbed when the plaster was immersed in a saturated solution of calcium sulphate at 20° C. varied from 31.3 to 50%. It was found that the best mixture is composed of $2\frac{1}{4}$ lb. of plaster to 1 quart of water. A larger proportion of plaster increased the strength, but reduced the porosity, lengthened the setting time, and raised the maximum temperature. With too little plaster, the rate of setting

is slow and the temperature attained is low. Each accelerator or retarder has its specific influence on the plaster. Thus, the addition of 10 c.c. of concentrated sulphuric acid gave a high temperature test in a shorter time and increased the porosity of the plaster, but reduced its strength to one-third. Common salt, alum, potassium sulphate, and potassium bichromate act similarly, potassium sulphate being the most active accelerator and sulphuric acid causing the greatest loss in strength. Gum tragacanth, dextrin, and sodium bicarbonate act as retarders, the last-named decreasing the porosity and seriously reducing the strength of the plaster.

The results of 25 experiments show that the use of accelerators and retarders increases the strength of the plaster, at the expense of the porosity, or *vice-versâ*.—A. B. S.

Fireclay, shale, and surface clay mixtures; Study of — with reference to their porosity-temperature relations. G. H. Brown. Trans. Amer. Ceram. Soc., 1915, 17, 450—457.

EIGHTEEN mixtures of No. 2 Killanning (Pa.) fireclay, Canton (Ohio) paving brick shale, and a surface clay from Groveport (Ohio) were made into small bricks, dried, and burned to various temperatures up to 1280° C. The addition of fireclay to a shale or surface clay does not prevent the tendency of the latter to overburn. The addition of 10–30% of fireclay to a surface clay or shale may improve the vitrification behaviour and decrease the porosity of the latter, though a higher firing temperature is necessary. Dissimilar clays cannot be satisfactorily blended, but retain their individual characteristics in the mixture.—A. B. S.

Fireclay mixture; Influence of varying water-content in a —. R. J. Montgomery and C. E. Fulton. Trans. Amer. Ceram. Soc., 1915, 17, 436—449.

THE variations in the proportion of water in a mixture of St. Louis fireclay and grog may be relatively large without materially affecting the physical structure of the mass during drying and burning. The property which is most affected is the shrinkage of the clay alone on drying, which is proportional to the amount of water used. A mixture of clay with 50% grog shows no marked variation.—A. B. S.

Grog; Effect of — in a fireclay body. C. E. Fulton and R. J. Montgomery. Trans. Amer. Ceram. Soc., 1915, 17, 409—420.

RAW St. Louis fireclay, ground so as to pass completely through a 20-mesh screen, was mixed with grog made by burning the same clay to about cone 6 and then crushing it to the desired size. *Effect of amount of grog.* The addition of grog reduces the amount of water required to develop plasticity, the drying and burning shrinkage, the strength of the unburned mixture, the tendency to over-fire at cones 15–20, and the strength up to the point of over-firing, and increases the apparent sp. gr. and apparent porosity. *Effect of size of grog.* Increasing the fineness of the grog increases the amount of water needed to develop plasticity; the drying and burning shrinkage, the latter especially at cones 15–20; the strength of the raw body; and, up to cone 15, the strength of the fired body. At cone 20 the change in the modulus of rupture clearly shows over-firing. The apparent sp. gr. is scarcely affected by the fineness of the grog below cone 20. The apparent porosity at cones 010 and 5 increases with the fineness of the grog; at cone 10 there is no effect, and at cones 15 and 20 the apparent porosity is reduced with increasing fineness of grog when the body is over-fired.—A. B. S.

Saturated sodium sulphate solution; Effect of — upon the structure of clay burned to different temperatures. W. L. Howat. Trans. Amer. Ceram. Soc., 1915, 17, 249—255.

BLOCKS of burned clay measuring 4 in. × 4 in. × 2½ in. were immersed in a cold saturated solution of Glauber's salt and then exposed to the air for a day to allow the salt to crystallise. The treatment was repeated as often as desired. A calcareous surface clay required to be heated to 1100° C. before it could withstand this treatment and it was then overburned. A shale became resistant at 1025° C. and a fireclay at 1100° C. The test appears to be sharp and decisive with clays which have not been burned sufficiently to reach their full strength, i.e., those with more than 8% porosity. It is much more severe than the freezing test.—A. B. S.

Porcelain mixture and shale; Electrical conductivity of — upon heating. C. S. Kinnison. Trans. Amer. Ceram. Soc., 1915, 17, 421—430.

A TYPICAL porcelain mixture and a Bedford (U.S.A.) shale were each made into cylinders, ¾ in. long and ¼ in. diam. Electrodes, consisting of platinum discs ¼ in. diam. to which were attached 4 in. of platinum wire, were embedded at each end of these cylinders and ¼ in. apart. The cylinders were then heated in an electric furnace, the temperature rising 1° C. per min. until vitrification occurred. The electrical conductivity was measured by a modified Wheatstone bridge with alternating current attachment, and a telephone. The conduction is probably of two kinds—corresponding to electron conduction through a copper bar and ionic or electrolytic conduction through a salt solution. The former predominates at low temperatures and the latter at a red heat or above. If a graph of the electrical conductivity and the temperature is plotted, the intersection of the two parts of the curve indicates the transition from the solid to the liquid phase of the material, the degree of sharpness varying with the abruptness of the melting point. The expression: $\log R = \frac{v}{T} + C$, where R = the specific

resistance, T = the absolute temperature, and v and C are constants depending on the material, may be deduced from van't Hoff's well-known formula. If $\log R$ is plotted as the ordinate and $\frac{1}{T}$ as the abscissa, the resulting graph shows two marked changes in direction. With a raw porcelain mixture the first change occurs at 980°–1000° C., and probably represents the beginning of sintering due to the active fluxes present as impurities in the clay. The second point, at 1125°–1135° C., probably indicates the commencement of the action of feldspar. A properly burned porcelain gives a perfectly smooth curve, indicating that no chemical changes occur below the softening point of the porcelain. With the shale, the first point, at 875° C., probably represents the fusing point of the most fusible eutectic, and that at 1080°–1100° C. the softening point of the principal eutectic. The author concludes that these materials (silicates) do not behave like alloys, but as electrolytes, and represent dissociated solutions. The large differences in the conductivity are due less to a change in the concentration of the ions than to their rate of motion, this depending on the viscosity.—A. B. S.

Dental porcelains. A. S. Watts. Trans. Amer. Ceram. Soc., 1915, 17, 190—199.

PORCELAINS used for the production of artificial teeth correspond in composition to the following mixtures:—

	A.	B.	C.	D.	E.
Felspar	81	80	89.5	61.06	12.02
Clay substance..	4	—	—	—	—
Flint	15	—	3.8	29.07	60.49
Quartz	—	20	—	—	—
Bone ash	—	5	—	—	—
Sodium carbonate	—	—	4.0	1.86	7.90
Calcium carbonate	—	—	2.7	4.21	1.43
Potassium carbon-	—	—	—	—	—
ate	—	—	—	1.98	7.21
Borax	—	—	—	0.83	10.45

The use of true porcelains for dental inlays has been almost completely replaced by that of porcelain (silicate) cements which consist of a powder composed of (i.) basic calcium and aluminium silicates, with or without beryllium nitrate, (ii.) zinc oxide, (iii.) calcined alumina, and a liquid which is a "modified" solution of phosphoric acid. An analysis of a commercial silicate cement showed the powder to consist of SiO_2 37.0, Al_2O_3 32.2, CaO 7.5, Na_2O 10.1, P_2O_5 1.9, F 9.3, and loss on ign. 2.0%, and the liquid to consist of Na_2O 6.0, P_2O_5 35.5, and water 58.5%.

In making true dental porcelains at York, Pa., the felspar is crushed, hand-picked, then ground in drag mills, 2 ft. 6 in. diameter, and mixed with kaolin, quartz, and a little starch and gum. The mixture is tinted with iron, titanium, cobalt, chromium, copper, manganese, gold, and other oxides. The teeth are made in bronze moulds, paste of the requisite colours being applied to the various parts of the mould. The mould with its contents is heated under pressure so as to bake the mixture lightly. The teeth are then removed, dressed, and burned in a gas-fired muffle on trays made of fused silica. The shortest possible heating is necessary to secure external fusion without warping. The teeth are then annealed in a separate furnace. The metal pins used to attach the teeth to the plate are preferably of platinum and are inserted before burning the teeth. If pins of base metal are used, they are generally soldered to platinum tips in the teeth. Attempts to produce dental porcelains at a temperature permitting base metal pins to be burned in the teeth have proved unsuccessful.—A. B. S.

Potash, lime, alumina, and silica; Study of the most fusible mixtures of —. H. H. Hanna. Trans. Amer. Ceram. Soc., 1915, 17, 672—690.

THE mixture of Canadian felspar, Florida kaolin, Ohio silica flint, and whiting which has the lowest deformation point (cone 3, 1140°C .) has a composition corresponding to silica 65.27, alumina 16.98, lime 5.04, and potash 12.71%. This mixture deforms 25°C . below the most fusible mixture described by Seger (cone 4). By replacing part of the potash by soda (microcline by albite), it was found that a mixture corresponding to 0.358 Na_2O , 0.142 K_2O , 0.500 CaO , 0.748 Al_2O_3 , 4.71 SiO_2 deforms at cone 2—3 (1120°C — 1140°C .). Other corresponding components and eutectics are: pure felspar, cone 6 (1200°C .); 8% kaolin and 92% felspar, cone 7 (1230°C .); 8% Tennessee ball clay and 92% felspar, cone 6 (1200°C .); 4% flint and 96% felspar, cone 7 (1230°C .). A mixture of lime 23.25, alumina 14.75, and silica 62.0% is the melting point eutectic and the deformation eutectic of the ternary CaO - Al_2O_3 - SiO_2 system; it is completely deformed at cone 6 (1200°C .).—A. B. S.

Colour of bricks; Experiments to overcome "scumming" [efflorescence] and improve the —. A. E. Williams. Trans. Amer. Ceram. Soc., 1915, 17, 764—770.

A SOLUTION of 0.7N ferric chloride (113 grms. Fe_2O_3 per litre) was sprayed on to a column of clay as it issued from an extrusion (wire-cut) brick

machine, the bricks being afterwards burned under commercial conditions. It was found that the colour of the bricks was improved, though with ferrous sulphate the results were unsatisfactory. A further set of experiments on a commercial scale, in which a 20% solution was applied to the clay by means of a roller covered with lamb's wool, produced a fairly good result, but weaker solutions were useless.—A. B. S.

Dryer "scum" on bricks; Use of barium fluoride for the prevention of —. H. F. Staley. Trans. Amer. Ceram. Soc., 1915, 17, 200—201.

BARIUM fluoride possesses the following advantages over other salts used to prevent the formation of efflorescence on bricks: (1) It is cheaper; (2) it is more soluble than barium carbonate; (3) smaller amounts are required; (4) there is no deleterious effect on the colour of the bricks; (5) the use of an excess does not produce a efflorescence, and (6) it promotes vitrification.—A. B. S.

Floor-tiles; Classification of — as related to degree of vitrification. F. K. Pence. Trans. Amer. Ceram. Soc., 1915, 17, 485—492.

THE author suggests that floor tiles shall be classified according to the average percentage (by weight) of water which they absorb when immersed in boiling water for one hour and then soaked in the same water for 24 hrs. Three classes are proposed, viz., vitreous, 0—2% absorption; semi-vitreous, 2—10%; plain unglazed, 10% or more absorption.—A. B. S.

Earthenware glazes free from boric acid. E. Berdel. Sprechsaal, 1916, 49, 346—347, 353—354. Z. angew. Chem., 1917, 30, Ref., 139.

GLAZES consisting of potassium, calcium, and lead mixtures, poor in silica, and free from boric acid, may be prepared which when fired are suitable for glaze-firing both at Seger cones 1—4 and at Seger cones 07—01. The mixtures suitable for higher temperatures are of the type 0.1—0.25 K_2O , 0.2—0.45 CaO , 0.4—0.7 PbO , 0.1—0.2 Al_2O_3 , 1.8—2.5 SiO_2 . The substitution of soda for potash was found to be unfavourable; it caused crazing. An increase in the lime caused matt results. For lower temperatures of firing, glazes of the type 0.15—0.3 K_2O , 0.05—0.2 CaO , 0.5—0.8 PbO , 0.05—0.07 Al_2O_3 , 1.5—2.2 SiO_2 are suitable. The glazes are not indifferent to underglaze colours containing chromium oxide; they produce a yellow zone of lead chromate. As regards the solubility of the lead in 4% acetic acid they conform to the legal specifications. Lead-free mixtures with such a low melting point and suitable glazing properties can hardly be prepared.—J. F. B.

Glazes; Lead oxide versus lead carbonate in —. A. S. Watts. Trans. Amer. Ceram. Soc., 1915, 17, 474—483.

A NOTABLE reduction in the cost of a glaze may sometimes be effected by substituting another lead compound for the one at present employed. The three available materials are litharge (PbO), minium or red lead (Pb_3O_4), and white lead ($2\text{PbCO}_3 \cdot \text{PbO} \cdot \text{H}_2\text{O}$). A number of commercial glazes, prepared with the lead in each of these three forms, showed that those containing litharge form a dense coating on drying, with no tendency to dust. Those containing red or white lead dust readily. White lead tends to produce a slight opacity; litharge gives a clearer and more liquid glaze which may have a faint yellow tint. The lowest lead oxide content and highest glossiness in the glaze are possible when the lead is introduced as litharge.—A. B. S.

Galena and lead-bearing waste materials as glaze ingredients. J. Miller. Trans. Amer. Ceram. Soc., 1915, 17, 779—792.

EXPERIMENTS have shown that the substitution of equivalent amounts of such plumbiferous waste products as "flue dust" or "baghouse dust" from lead smelters, or of cheap sources of lead, such as galena and lead sulphate, for the purer lead pigments is satisfactory for glazing bricks, sewer-pipes, drain tiles, and other common wares. The disadvantages accompanying the use of these materials are: galena introduces sulphur into the glaze and may cause semi-opacity; lead sulphate can only be used economically when purchased in a dry calcined form, but is quite satisfactory at cones 02—2 (1060—1120° C.) in shale and fire-clay bodies; the "flue dust" and "baghouse dust" give better results than either of the foregoing, but are liable to produce a red colour (possibly due to antimony oxysulphide) or slight opacity; they also introduce carbon, sulphur, and volatile impurities, and the glazes containing them require very careful firing.—A. B. S.

Pinholing of glazes: An unusual case of —. H. J. Knollman. Trans. Amer. Ceram. Soc., 1915, 17, 165—172.

WHILE there are undoubtedly several causes of "pinholes" in glazes, the main one is the action of sulphur during the water-smoking period of burning. The moisture evolved during this period combines with the sulphur dioxide and trioxide in the fire-gases, forming sulphuric acid which is deposited as a dew on the glaze, particularly on goods placed in the cooler parts of the kiln. This explains why pinholes are more frequent in a closely set kiln than in a more open one. The appearance of pinholes also coincides with glazes of excessive viscosity. The remedy consists in adding a flux to the glaze or in employing a "softer RO content" so as to increase its fusibility. A slight increase in the proportion of alumina or silica in the glaze will sometimes cause pinholing. Re-firing the glazed goods will sometimes remove the pinholes. A sharp quick fire at the finish of the burning increases the fluidity of the glaze and lessens the loss by volatilisation and so prevents the formation of pinholes.—A. B. S.

White terra-cotta glazes at cones 6 and 7. E. C. Hill. Trans. Amer. Ceram. Soc., 1915, 17, 380—408.

TIN oxide and barium oxide were added to terra-cotta glazes of the Bristol type, consisting of felspar, whiting, zinc oxide, ball clay, and flint. The replacement of lime by tin oxide reduces the gloss, but with baryta no change occurs. The opacity and whiteness of these glazes are increased by keeping the alumina low and by adding either tin oxide or baryta, but the former is much more effective. With a low proportion of zinc oxide, tin oxide tends to produce a pink colour, whilst a high zinc oxide content prevents the pink discoloration and increases the glossiness, but tends to form blisters on account of its volatilisation. Glossiness is also reduced by an increase of alumina or clay or by a reduction of felspar. Notwithstanding the greater complexity of the glazes used due to the added tin oxide and baryta, the results agree with previously published results on Bristol and terra-cotta glazes with one exception, viz., Purdy (this J., 1903, 1017) found that a considerable proportion of clay must be added to Bristol glazes to obtain the maximum fusibility, whereas the author found that any increase in the proportion of clay had precisely the opposite effect.

—A. B. S.

Chrome-tin red glazes between cones 2 and 8. B. S. Radcliffe and C. L. Walduck. Trans. Amer. Ceram. Soc., 1915, 17, 278—289.

A MIXTURE of tin oxide 622.4, flint 247.6, whiting 930.0, and lead chromate 200.0 parts was calcined in a sagger to cone 8 in 28 hrs. It was then washed well and dried. This formed the stain used for colouring various glazes composed of felspar, whiting, barium carbonate, white lead, clay, flint, and boric oxide.

Of the glazes in Group A (constant RO, varying Al_2O_3 : SiO_2 ratio; cones 6—8, 1200—1250° C.) the best result was obtained with a mixture corresponding to 0.095 K_2O , 0.620 CaO , 0.188 BaO , 0.097 PbO , 0.281 Al_2O_3 , 0.0088 Cr_2O_3 , 2.00 SiO_2 , 0.118 SnO_2 .

In Group B (0.281 Al_2O_3 , 2.00 SiO_2 ; varying RO and boric acid), the best glaze at cone 8 is composed of (0.189 K_2O , 0.716 CaO , 0.071 PbO , 0.021 BaO , 0.284 Al_2O_3 , 0.0088 Cr_2O_3 , 0.118 B_2O_3 , 2.00 SiO_2 , 0.118 SnO_2). This glaze is of a dark raspberry red colour, opaque, and does not craze or crawl. At cone 4, the best glaze in Group B is composed of (0.189 K_2O , 0.621 CaO , 0.166 PbO , 0.021 BaO , 0.281 Al_2O_3 , 0.0088 Cr_2O_3 , 0.188 B_2O_3 , 2.00 SiO_2 , 0.118 SnO_2), and has a colour between raspberry and cherry red. A better colour—blood red—though inferior in gloss, corresponds to (0.189 K_2O , 0.527 CaO , 0.024 BaO , 0.260 PbO , 0.281 Al_2O_3 , 0.118 B_2O_3 , 0.0088 Cr_2O_3 , 2.0 SiO_2 , 0.118 SnO_2). At cone 2 the best glaze in Group B is opaque and shows no defects; it corresponds to (0.189 K_2O , 0.621 CaO , 0.142 PbO , 0.048 BaO , 0.284 Al_2O_3 , 0.237 B_2O_3 , 0.0088 Cr_2O_3 , 2.00 SiO_2 , 0.118 SnO_2). Hence, good colours can be made using chrome-tin stain, and these burn well between cones 2 and 8 provided the glaze matures properly at the selected temperature. In such glazes the addition of boric oxide changes the colour from raspberry to cherry red, but if over-burning occurs a green glaze is produced. The partial replacement of lime (1) by calcium fluoride has no effect on the colour but makes the glaze dull, (2) by magnesia produces mottled glazes, (3) by baryta produces a brownish red, and (4) by bismuth oxide produces a softer mottled green and red glaze. Hence the composition of the RO portion of a chrome-tin glaze has a marked effect on its colour.—A. B. S.

Zinc compounds in a chrome green glaze: Influence of some unusual —. R. H. Minton. Trans. Amer. Ceram. Soc., 1915, 17, 667—671.

BROWN and pink colours are produced by the formation of zinc chromates in glazes containing chromium and zinc oxides, the tint depending on the conditions of heating and on the compound of zinc used. Zinc chromate produces the strongest brown and zinc phosphate the strongest pink. No greens were produced in any of the mixtures containing zinc, as the green colour due to chromic oxide is destroyed by the zinc salts.—A. B. S.

Soda-zinc oxide-silica and soda-zinc oxide-titanic oxide-silica: Microscopic investigations of some compounds noted in the systems —. A. A. Klein and G. H. Brown. Trans. Amer. Ceram. Soc., 1915, 17, 745—759.

IN molten mixtures of the soda-zinc oxide-silica system within the following molecular percentage limits: SiO_2 90%, ZnO 10%; ZnO 10%, Na_2O 50%, SiO_2 40%; and ZnO 60%, SiO_2 40%, glassy, matt, and crystalline structures occur. In the matt and crystalline products, with one exception (ZnO 10%, Na_2O 10%, SiO_2 80%), prismatic needle crystals of hexagonal cross section and consisting of zinc orthosilicate separate out and resemble the mineral willenite. The maximum indices of the glassy structure follow the Lorentz-Lorenz law of specific refractivities (Wied,

Annalen, 1880, 9, 641; 2, 70). In the soda-zinc oxide-titanic oxide-silica system, glassy, matt, and crystalline structures also occur. Two types of crystal are found: one is zinc orthosilicate containing a little titanic oxide; the composition of the other is unknown, but its high refraction and double refraction suggest either zinc titanate or titanium dioxide.—A. B. S.

Enamels; Antimony compounds as opacifiers in —. H. F. Staley. Trans. Amer. Ceram. Soc., 1915, 17, 173-189.

THE use of antimony compounds as opacifiers in enamels is beset with difficulties which have hindered their general use, but with careful attention to the following precautions, satisfactory results may be obtained. For a good gloss, the enamels should be one of the following types: (i.) High boric oxide, leadless enamel as A; (ii.) medium boric oxide, leadless enamel as B; (iii.) low boric oxide, plumbiferous enamel as C.

	A.	B.	C.
Felspar	425	425	425
Borax	500	325	200
Soda ash	—	57	57
Sodium nitrate	27	27	27
Barium carbonate	—	90	90
Whiting	—	27	27
Fluorspar	—	100	85
Cryolite	100	—	—
Zinc oxide	125	100	80
Red lead	—	—	102
Antimony oxide	75	75	75

Enamels containing antimony compounds yield three colours: (i.) a tan, due to sulphur, which fades as the melting proceeds; (ii.) a persistent yellow due to lead oxide; and (iii.) a blue due to a combination of antimony oxide, boric oxide, calcium, and fluorine. Opaque white enamels are the result of balancing the yellow and blue colours by adjusting the proportion of lead and cobalt oxides, and by appropriate heating. The dark specks in enamels containing antimony oxide are due to dirt introduced after melting the enamel. They do not occur in carefully conducted laboratory experiments.—A. B. S.

Ferric iron; Role of chlorides in the volatilisation of — [from enamels]. G. A. Bole and R. M. Howe. Trans. Amer. Ceram. Soc., 1915, 17, 125-129.

To an enamel with the following formula (0.2 K₂O, 0.3 CaO, 0.5 PbO) (0.25 Al₂O₃, 0.08 Fe₂O₃), (2.8 SiO₂, 0.15 SnO₂), and thus containing 2.5% Fe, about 5% of a chloride was added. The mixture was fused completely at cone 04 (1020° C.) and was kept at this temperature for 5 hrs. The power of barium chloride to cause volatilisation of the iron was nil, and the chlorides of sodium, potassium, and magnesium were all feeble in this respect. The best results were obtained by the addition of lithium chloride, lead chloride, silver chloride, and stannous chloride. As the prices of tin oxide and chloride are equivalent to the metallic content, the use of tin chloride in enamels is preferable, inasmuch as it effects a partial volatilisation of the iron present.—A. B. S.

Enamel; Relative action of acids on —. E. P. Poste. Trans. Amer. Ceram. Soc., 1915, 17, 136-149; 1916, 18, 762-766.

Two grms. of finely powdered enamel was placed in a 400 c.c. beaker, 100 c.c. of the acid added and mixed by stirring. The beaker and contents were then allowed to stand for 24 hours, after which the liquid was passed through a weighed Gooch crucible with asbestos filter, and the residue

(in the crucible) dried and weighed. With the exception of acetic acid, the loss of weight increases with the concentration of the acid with solutions below 10%, but then diminishes rapidly to a minimum solubility of 0.015 gm. The effect of time is to increase the solubility, and the ratio of the surface area of the enamel to the volume of the acid is important.

In a second set of experiments, the enamel was ground and sifted, the particles (a) passing an 80-mesh and retained on a 100-mesh sieve, or (b) passing a 100-mesh and retained on a 150-mesh sieve, being used for testing as follows:—2 grms. of the selected portion of the enamel was immersed in 100 c.c. of 11.8% hydrochloric acid for 24 hrs. at 21° C. (70° F.). The loss in weight was found to be constant for any given size of particles. In another series of tests 2 grms. of the sample was heated with 13.6% hydrochloric acid under a reflux condenser. The loss in weight was proportional to the rise in temperature of the acid up to 50° C., but after this it remained almost constant. In the discussion, H. F. Staley pointed out that the solubility of the enamel corresponded very closely with the electrical conductivity of the acid solution at various strengths.—A. B. S.

The ternary system potassium metasilicate-silica-water. Morey and Fenner. See VII.

PATENTS.

Crucibles [for glass melting or annealing]. J. Gray, London. Eng. Pat. 106,547, June 26, 1916. (Appl. No. 8970 of 1916.)

A CRUCIBLE particularly suitable for melting or annealing glass without contamination by the material of the crucible, is made from plates or staves of tungsten, tantalum, or other refractory material held together by detachable bands in the same manner as in a barrel. The joints may also be soldered with fused tungsten or other suitable fused metal. In a modification the staves are clamped at the top by a water-cooled electrically-conducting clamp, and the bottom dips into a water-cooled mercury receptacle. The crucible is heated by a current passing longitudinally through it.—W. F. F.

Silica [quartz]; Process for treating [fusing] —. I. Rosenblum, Swampscott, Mass., U.S. Pat. 1,229,324, June 12, 1917. Date of appl. Mar. 31, 1917.

QUARTZ is heated in a graphite crucible in an electric furnace at 1400°-1700° C., in an atmosphere of nitrogen. A protective layer is formed on the crucible by the interaction of a part of the quartz with the crucible lining, and the temperature is then raised to fuse the quartz.—W. F. F.

China clay; Treatment of —. W. Feldenheimer, London. Eng. Pat. 106,890, July 10, 1916. (Appl. No. 9726 of 1916.)

To remove "mica" from china clay or other clay, the clay is washed in the usual way over "mica drags," using washing water containing a minimum of 0.06% of sodium carbonate for a 5% suspension of clay. A larger proportion of "mica" is thus deposited. The clay is then passed to a settling tank for further deposition of "mica," and finally to a tank where a weak solution of alum is added to neutralise the solution and cause the deposition of the clay.—W. F. F.

Refractory materials; Production of —. P. R. Hershman, Assignor to Armour Fertilizer Works, Chicago, Ill. U.S. Pat. 1,227,909, May 29, 1917. Date of appl. Oct. 21, 1916.

A MIXTURE of alumina and carbon is heated to sintering temperature (1800°-1900° C.) in an atmosphere containing an excess of reducing gas.

The product is pulverised, mixed with carbon and a suitable binder, moulded, and heated to about 1950° C. in a reducing atmosphere.—W. F. F.

Argillaceous composition and process of making the same. L. H. Minton, Metuchen, N.J., Assignor to A. W. Herbst, Philadelphia, Pa. U.S. Pat. 1,228,465, June 5, 1917. Date of appl. Nov. 29, 1916.

TERRA-COTTA is made from a mixture of stoneware clay 30%, low-grade fireclay 30%, and subdivided acid furnace slag substantially free from metallic iron, poor in lime, and rich in silica, 10%. The mixture is moulded, dried, and heated to a temperature sufficient to destroy the plasticity of the clay but below sintering temperature.—W. F. F.

Glass-melting pots; Manufacture of—G. M. Bowen, Birmingham. Eng. Pat. 106,871, June 13, 1916. (Appl. No. 8318 of 1916.)

IX.—BUILDING MATERIALS.

Sand-lime bricks; Silica bond in—W. E. Emley, A. A. Klein, and E. M. Sanborn. Trans. Amer. Ceram. Soc., 1915, 17, 471—473.

A CRITICISM of the work of Parr and Ernest (Illinois State Geolog. Survey Bull. 18; Trans. Amer. Ceram. Soc., 1911, 13, 648; this J., 1911, 1387) showing that their conclusions are largely erroneous for the following reasons:—(1) No method has yet been found for isolating the free lime in a mixture of calcium silicates and lime; (2) there is no justification for supposing that $2\text{CaO} \cdot \text{SiO}_2$ and $\text{CaO} \cdot 2\text{SiO}_2$ occur in sand-lime bricks; (3) the evidence to show that calcium silicate forms no definite hydrate is inconclusive; (4) in their petrographic examinations Parr and Ernest used only thin sections, whereas it has repeatedly been shown that the only reliable method is to use immersed grains; and (5) the grains which Parr and Ernest believed to be zeolites have been identified as calcium carbonate by the authors of the present paper.—A. B. S.

Estrich [flooring] plaster; Note on—R. K. Hursh. Trans. Amer. Ceram. Soc., 1915, 17, 549—556.

ESTRICH plaster is made commercially by heating gypsum at 900°—1000° C. The author finds that flooring plaster of maximum tensile strength is produced by heating gypsum to only 700° C., or 200°—300° C. lower than commercial practice, but adds that the higher temperature may be requisite to obtain constancy of volume during the setting of the plaster—a property of great importance. The full strength of Estrich plaster requires several weeks to develop, but is then comparable with that of Portland cement.—A. B. S.

Wood; Impregnation of—with mercuric chloride solution. R. Nowotny. Elektrotechnik, 1916, No. 39, 1. Z. angew. Chem., 1917, 30, Ref., 136.

THE amount of mercuric chloride absorbed by wood immersed for some days in a solution of the salt, is in excess of the amount corresponding to the volume and concentration of the saturating liquid. The excess increases with increasing volume of solution, is proportional to the initial concentration, and is independent of the quantity of solution absorbed by the wood. There is no definite relation between the normal absorption and the excess.—F. C. T.

Toxic action of maplewood creosote and of some of its constituents and derivatives on a wood-destroying fungus. Pieper and others. See III.

Titration of calcium oxide or hydroxide in presence of some aluminates or silicates. Emley. See VII.

Notes on manufacture of plaster moulds. Williams. See VIII.

PATENTS.

Paving material; Process of producing—G. C. Glynn, Kansas City, Kans. U.S. Pat. 1,227,903, May 29, 1917. Date of appl. Dec. 20, 1916.

Soil containing colloidal matter is mixed with a deflocculating agent and water, heated, and liquid bitumen added. The material is dried in air and then melted.—W. F. F.

Lumber and other moisture-bearing substances; Dry-kiln for drying—H. D. Tiemann, Madison, Wis. U.S. Pat. 1,228,989, June 5, 1917. Date of appl., Dec. 18, 1915.

THE kiln consists of a closed chamber containing heating pipes arranged so as to produce an ascending column of heated air along one side of the pile of lumber, which is so arranged that the heated air may pass freely downward through the pile in cooling, and a space is left on the opposite side of the pile through which the cooled air may descend; a vertical flue near the bottom of the pile into which the cooled descending column of air may enter; a spray of water in this flue; means for regulating the temperature of the spray of water; baffle-plates near the bottom of the flue for separating the mist from the air.—J. F. B.

Porous blocks; Method of treating [impregnating]—C. E. Fuller, Kansas City, Mo. U.S. Pat. 1,229,439, June 12, 1917. Date of appl., Oct. 20, 1916.

POROUS blocks are impregnated with melted bitumen at a pressure above atmospheric, and then subjected to a vacuum before the liquid solidifies, and subsequently to pressure during solidification of the liquid.—W. F. F.

Heat-insulating material and process of producing same. H. A. Ashenhurst, Assignor to J. J. Reynolds, Chicago, Ill. U.S. Pat. 1,230,085, June 12, 1917. Date of appl., Oct. 30, 1916.

A COMPOSITION of cellular structure with a specific gravity less than 1 consists mainly of finely divided asbestos together with aluminium hydroxide and a substance such as calcium sulphate which sets hydraulically after the reaction by which the cellular structure is formed.—F.W.A.

Concrete structures; Method of and means for preventing the disintegration of—H. P. Brown, Montclair, N.J. U.S. Pat. 1,230,373, June 19, 1917. Date of appl., June 8, 1912.

TO prevent disintegration of reinforced concrete structures by electrolytic action, the reinforcing elements are coated with a dense waterproof concrete by "jetting" at a pressure of 30—60 lb. per sq. in., and the coated elements are then embedded in concrete in the usual way.—W. F. F.

Furnace lining and method of making same. G. W. Patnoe, Maple Grove, Ohio, Assignor to The Dolomite Products Co., Cleveland, Ohio. U.S. Pat. 1,230,430, June 19, 1917. Date of appl., Nov. 16, 1915.

A REFRACTORY material for furnace linings and the like is made by mixing magnesian limestone with 2—5% of "argillaceous matter in the form of silica, alumina, and iron oxide," grinding the mixture till substantially all of it passes through a 100-mesh sieve, and then calcining it at 2600°—3000° F. (1430°—1650° C.) until it is converted into a dense sintered mass impervious to air and moisture.—W. F. F.

Magnesia cement; Process for the manufacture of — A. Reich. Budapest. Ger. Pat. 297,431. Mar. 21, 1915. Under-Int. Conv., Mar. 21, 1914.

BURNT or unburnt magnesite is mixed with solutions of acid sulphates; if desired, free sulphuric acid may be added to the mixture. Magnesium oxide mixed with sodium bisulphate forms a double salt $\text{MgSO}_4 \cdot \text{Na}_2\text{SO}_4$ which gives with magnesium oxide a fluid and easy setting cement. —J. F. B.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Titaniferous iron ores; Electric smelting of — A. Stansfield. Canadian Geol. Survey, Bull. 92. Eng. and Min. J., 1917. 103, 1020.

A DEPOSIT of titaniferous magnetite estimated to contain 1,000,000—5,000,000 tons occurs near St. Charles, Quebec. Electric power may be obtained close by from the Saguenay River, and supplies of charcoal and limestone are also available. The ore contains iron 50.53, titanium 10.55, sulphur 0.02, and phosphorus 0.03%, and yields a magnetic concentrate assaying iron 56.2 and titanium 8.3%. It is estimated that 1.75 tons of concentrate smelted in a Swedish furnace would yield 1 ton of pig iron with 0.4% of titanium, and 0.7 ton of slag containing titanium 34 and silica 14%. The electric power required would approximate 0.55 H.-P.-year per ton of metal; the total cost of production would be \$17.93 per ton.—W. R. S.

Ferrosilicon; Metallurgy of — R. J. Anderson. Eng. and Min. J., 1917. 103, 1095—1098.

FERROSILICON is second in importance only to ferromanganese as regards tonnage consumed, in the metallurgy of iron and steel. Analyses of ferrosilicon used in steel manufacture either as deoxidisers or in the production of silicon steels show a content of silicon ranging from 8% (English blast furnace) to 94.8% (electric furnace). The structure is finely or coarsely crystalline depending on the silicon content; distinct crystallisation is absent in high-grade alloys containing over 50% Si, the fracture being fine, and of a bluish colour. The number of iron-silicon compounds is open to dispute; at least three exist, namely, Fe_2Si , FeSi , and FeSi_2 . Tammann and Guertler's researches indicate the existence of two eutectics, the first containing 21.6% Si, and composed of Fe_2Si and FeSi , the second one containing 60% Si and composed of FeSi and Si. Impurities present in electric furnace ferrosilicon are chiefly due to the raw materials charged: manganese is generally low, 0.10% to 0.40%; phosphorus from 0.01% to 0.05%; sulphur from 0.01% to 0.05%, and carbon from nil to 0.30%. In general the higher the silicon content the lower the impurities. In the blast-furnace product manganese ranges from 1.25% to 2.5%, phosphorus is usually less than 0.06%, sulphur less than 0.05%, and carbon varies from 1 to 2%. In the 25% grade calcium may be about 0.5% and increases up to 1% in the 90% grade; aluminium averages about 0.1% in most grades. Ferrosilicon-aluminium is an alloy containing about 45% Si, 12 to 15% Al, and the remainder iron; it is used as a deoxidiser for steel made in the electric furnace. It is more effective than aluminium, and is usually added to the ladle before teeming. Ferrosilico-manganese is of two grades, 60% to 70% Mn, 20 to 25% Si, and 3 to 4% Fe; and 50 to 60% Mn, 22 to 25% Si, and about 19% Fe; in both the carbon is about 0.35% and sulphur and phosphorus low. The alloys are used at times for adding silicon and manganese to steel. Ferrosilico-manganese-alumin-

ium is made in two grades containing 18 to 20 or 9 to 11% Si, 18 to 22 or 9 to 11% Mn, and 9 to 12 or 4.5 to 6% Al. Ferrosilico-calcium-aluminium has an average composition of 50 to 55% Mn, 18 to 22% Ca, 12 to 15% Fe, 4 to 5% Al, and about 1% C; this alloy is a deoxidiser and desulphuriser; its use is limited to high-grade steels. Silico-spiegel contains 22 to 24% Si and 35 to 40% Mn, and is made by melting together ferrosilicon, flint, manganese ore, and carbon. Ferrosilicon is made either in the blast furnace or the electric furnace and is also produced from two different charges; first by reducing silica and iron ore with carbon, and second by the reduction of silica with carbon, iron being added in the form of turnings. Experiments with iron-silicon slags indicate that their use is not practicable commercially. The blast furnace product does not contain more than 20% Si, the higher grades being produced in the electric furnace; even in making 15% alloy in the blast furnace, fuel consumption is high. Iron oxide, silicious iron ore, and coke are used in blast-furnace charges, and the most suitable slags are high in alumina and low in lime. In the electric furnace, two kinds of charges are used, quartz or sand, and charcoal, coke, or coal with either wrought iron, steel, or cast iron turnings or silicious iron ore; using turnings instead of iron ore power consumption is less, furnace operation steadier, and less slag is formed; purity of materials is necessary as most of the phosphorus and sulphur appears in the metal. The liquid metal is highly corrosive towards iron and is therefore tapped out into sand or carbon-lined cars or sand moulds. The electric furnace product is in four grades, 25 to 30%, 45 to 55%, 75 to 80%, and 90 to 95% Si and higher. Packing and transport, particularly of grades 30 to 65% Si, is important, cases of poisoning having been traced to the disintegration of the alloys; the gases evolved were hydrogen phosphide and arsenide. The tendency to decomposition is not so marked in alloys containing less than 30% Si; the richer alloys, over 65% Si, are also less liable to spontaneous disintegration. Silicon promotes soundness in ingot iron but should not exceed 0.15% in metal which has to be rolled; about 0.30% promotes soundness in steel castings; it is probable that carbon is detrimental to silicon steel. Usually the 25 to 30% alloy is used for making fixed additions of silicon, the 45 to 50% grade for deoxidising purposes. Though the addition of silicon to iron increases its elastic limit and tenacity, a loss in ductility is caused, but in well-annealed material this is not marked until the silicon reaches 3%; above this amount, ductility loss increases rapidly.—T. H. B.

Carbon steels; Mechanism of the hardening of — P. Chevenard. Comptes rend., 1917. 165, 59—62.

THE rate of cooling, in an inert atmosphere, of a steel wire, after heating to a red heat by an electric current, varies largely with the nature of the gas. Hydrogen generally produces hardening, while in nitrogen, annealing usually occurs, and with a mixture of the two gases, a whole range of intermediate conditions can be obtained. By means of a registering differential dilatometer, the curve, which is traced photographically, of the thermal dilatation during cooling records transformations in the metal with great sensitiveness, and the method is almost independent of the rate of cooling. In the curve which is traced, the ordinate gives the difference of expansion of the wire which is being studied and a standard wire of "baros" alloy which is maintained at the same temperature. The temperature is recorded by the expansion of the standard which traverses the abscissa axis of the curve. The two wires of 0.23 mm. diameter are held close together in a gas-tight case and connected with an adjustable electric circuit by which the current through the

two filaments is regulated so as to give equality of temperature, which is judged optically. After any particular thermal treatment a microscopical and mechanical examination is made of the metal. With a given steel and identical conditions of cooling, the nature of the transformation was found to depend on the temperature reached during the heating. When the initial temperature of the metal was gradually raised, the transformation corresponding to the formation of pearlite of minimum hardness, which normally occurs at 600° – 650° C., is gradually lowered. Above a certain temperature of initial heating θ_0 , the transformation occurs in two stages, one reverting to a temperature of 200° – 300° C. With further increase of temperature the proportion which reverts increases, and at a certain temperature, θ_1 , reversion is complete. On increasing the rate of cooling, the temperatures, θ_0 and θ_1 , are rapidly lowered, approach each other, and finally coincide. The transformation which reverts to the lower temperature corresponds to the formation of martensite, i.e., to the condition of maximum hardness. The phenomena are more complex in the cases in which the transformation occurs in two stages, but it was found possible to obtain products which microscopic examination showed to contain both troostite and martensite. The speed of cooling with very fine wires is probably greater than can be obtained with more massive samples; in the latter case, the internal pressure produced during the contraction tends to oppose the passage from the γ to the α state.—J. N. P.

Steel: Anomalous dilatation due to cementite in carbon—. P. Chevenard. Comptes rend., 1917, 164, 1005–1008.

A NUMBER of samples of steel of high purity were prepared by melting Swedish iron with electrode graphite in an electric furnace. Measurements of dilatation during regulated heating were made by a registering differential dilatometer with bars of metal 10 cm. long in a gauge in which carbon-free electrolytic iron was used as a standard of comparison. The differential curves obtained showed that with all samples an anomalous negative dilatation occurs which is reversible and similar to the negative dilatation shown by ferro-nickel alloys. The departure from the value for pure iron varied with the content of carbon and at 15° C. could be expressed by the value 3.3×10^{-4} C., where C is the percentage of carbon. The curves representing the differential of the expansion showed a bend at 210° C., which coincides with the temperature at which a sudden fall in magnetisation has been found to occur with cementite. Beyond 300° C. the curves became almost rectilinear, denoting a constant difference in the dilatation of iron and the steels. The amplitude of the curves varies with the content of carbon and the previous heat treatment and enables the changes in carbide formation to be followed comparatively with those indicated by micrographical examination. The identity of constitution of pearlite and sorbite was thus revealed, and measurements made with partially hardened steels containing troostite and martensite showed that troostite is a complex of the phases ferrite and cementite which are stable at ordinary temperatures.—J. N. P.

Manganese steels. A. Portevin. Comptes rend., 1917, 165, 62–65.

PEARLITE in laminated form, together with martensite, can be produced in steels containing 7% manganese and 0.5%–1% carbon, by reheating to 1300° C., followed by very slow cooling (extending over 75 hours). The clusters of pearlite possess a rounded and nodular form which are often considered to be limited to troostite in a medium of martensite or austenite. In the present instance

the laminated crystals of pearlite in the clusters have a stellated or fan-shaped form. By reheating to 1000° C., and cooling in 5 hours, these steels return to the austenite condition with a correlated variation of the mechanical and physical properties. For example, a steel containing 8.6% Mn and 0.08% C had a Brinell hardness of 435 and specific resistance 51.1 microhms per centimetre cube after the very slow cooling, whereas after reheating to 1000° C., and cooling in 5 hours, the hardness was 217 and the resistance 63.1 microhms. A measurement of the differential expansion of the hardened steel during the cooling showed a marked transformation point at 640° C. With a steel containing about 12% Mn and 1% C it has been possible by very slow cooling to obtain laminated pearlite and austenite separated by a narrow border of troostite. The clusters of pearlite present in some cases the external morphological character which is customary to troostite. By ordinary reheating and cooling the whole changes to austenite, while by cooling very slowly from a temperature of 1300° C., a partial transformation at a high temperature to pearlite and troostite can be obtained in manganese steels which are originally austenite, the residual austenite remaining unchanged or undergoing a transformation at a low temperature leading to martensite. Micrographical examination of nickel and tungsten steels gave results which are difficult to interpret and seem to indicate a new constituent.—J. N. P.

Iron-nickel alloys: Changes in the dilatations of — under the influence of various thermal and mechanical treatments. C. E. Guillaume. Comptes rend., 1917, 164, 904–906. (See also this J., 1917, 31.)

THE experiments previously recorded on "invar" have been extended to other iron-nickel alloys. Eight alloys, with nickel content varying from 27.5% to 69.0%, were examined ("invar" contains 36%). The alloys were quenched, annealed, annealed in a porcelain kiln at 1000° C., followed by slow cooling lasting three or four days, also quenched and drawn so as to produce an extension of 50%. Two alloys with nickel content 27.5% and 27.6% showed an increased coefficient of expansion as a result of any form of treatment applied. One alloy (Ni 28.7%) showed a decreased dilatation in all cases. The other samples (Ni, 42.0, 43.0, 49.8, 55.8, 69.0% respectively) behaved like invar, but the changes produced were much smaller.—H. J. H.

Alloys to replace platinum; New—. F. A. Fahrenwald. J. Ind. Eng. Chem., 1917, 9, 590–597. (See also this J., 1916, 543; 1917, 81, 460, 670.)

ALLOYS of gold and palladium, as the chief constituents, were prepared, and gave results which for many purposes were quite equal to those given by platinum. The name "rhotanium" has been given to this series of alloys, which contain from 90 to 60% of gold, according to the purposes for which they are required. For certain electrical and other uses the addition of a small proportion of rhodium is essential, but this is not necessary in the case of material for chemical ware. A small amount of silver may also be introduced into alloys which are not intended for chemical purposes. In the preparation of rhotanium alloys great care is required to obviate the affinity of palladium for gases and solids ordinarily met with in manufacturing processes, and also to regulate the heat so as to prevent segregation of the constituents. The slightest want of homogeneity makes the alloy worthless for many purposes, and especially for chemical requirements. Comparative tests with boiling acids, alkali and alkali

sulphide solutions, and by fusion with potassium bisulphate showed that, excepting for use with nitric acid, an alloy may be chosen which will give results equal to or better than those given by platinum. The loss by volatilisation in 10 hours at temperatures of 1050° to 1400° C. was lower than for platinum in the case of some of the alloys. At 1400° C. the crystalline structure was clearly shown, but no brittleness was produced. Some of the alloys are practically indistinguishable from platinum in colour, and are equally malleable and ductile. They melt at temperatures up to 1450° C., and have an electrical conductivity and tensile strength equal or superior to those properties of platinum. The sp. gr. varies from 18.5 to about 16.0 (platinum 21.5), and the temperature coefficient is much lower than that of platinum. These alloys may be welded readily at white heat without the use of a flux, and may be made into any shape while either cold or hot. Rhotanium has been found suitable for contact terminals in automatic-electric devices, and in most other cases where it has been found necessary to use a platinum alloy containing a large proportion of iridium, but it has not given uniformly satisfactory results in magnetos. For dental work it has proved as useful as platinum for most purposes. It cannot be used in chemical work, as an anode in electrolytic analysis, or when exposed to the action of strong nitric acid, but is a satisfactory material for cathodes. It is superior to platinum for jewellery, being harder, stronger, and taking a better finish. It may be "sweated" or otherwise treated as platinum without darkening or oxidising, and the finished articles cannot be distinguished by ordinary means from those of platinum.—C. A. M.

Copper ores; Leaching of low-grade——. J. Irving. Eng. and Min. J., 1917, 103, 932—933.

Two new plants for leaching oxidised ores are being erected, by the New Cornelia Copper Co., at Ajo, Ariz., and by the Utah Copper Co., at Bingham, Utah. At the latter plant it is proposed to treat the ore without a preliminary roast, tests having shown that a fair proportion of the gold and silver can be recovered with the copper in this way. It has been demonstrated that the waste liquors left after precipitation of the copper by iron can be used advantageously for leaching, after aeration, the ores being first treated with regenerated liquor, followed by sulphuric acid. A great saving of acid is thus effected in the case of ores rich in alumina and lime. Mixed oxide-sulphide ores may be crushed and concentrated with regenerated liquor and the mill solution treated for the recovery of the dissolved metal. Experimental leaching of large heaps of poor ores without using any other plant than a prepared floor has given very promising results at the Copper Queen Mine, Bisbee, Arizona. A recovery of 80% after two years' leaching may be expected. —W. R. S.

Copper; Purity of "selected"——made in converters. H. F. Collins. Bull. 153, Inst. Min. and Met. [Advance copy.] 3 pages.

AFTER the outbreak of the war, the Huelva Copper Co. adopted the "bottom" process (this J., 1915, 618) to save part of the gold contents and obtain a product which could be sold locally. The copper is sold at £1-£2 less than "Best Selected" and is suitable for alloy-making as regards freedom from impurities, though too brittle for rolling on account of a slight excess of oxygen. To remove the latter, the metal must be re-melted in a reverberatory furnace, and poled. This process is carried out in an Australian works. The following figures indicate the purity of the metal produced:—

	Spain.		Australian copper.
	Selected copper.	Bottom copper.	
Copper	99.41	97.97	99.62
Silver	0.1060	0.1724	—
Gold	0.0010	0.0206	—
Ni + Co	0.1222	0.2410	0.2800
Iron	0.0353	0.5600	0.0030
Sulphur	0.0364	0.7770	trace
O + loss	0.2348	0.1302	0.0890

—W. R. S.

Copper-nickel sulphide ores; Smelting of——[in the electric furnace]. A. von Zeerleder. Metall. u. Erz. 1916, 13, 453—462, 473—481, 494—505. Z. angew. Chem., 1917, 30, Ref., 130.

SMELTING experiments were made in an electric shaft furnace on a copper-nickel sulphide ore from the Black Forest, which contained 1.3% Ni, 0.44% Cu, 14.7% Fe, 4.5% S, and 45% SiO₂, and has hitherto been neglected mainly on account of the low nickel content. The furnace product gave, on solidification, a nickel-copper matte, below which was a layer of a heavy compound of iron, nickel, and silicon containing only a very small quantity of sulphur and copper. Experiments made on a larger scale in a Girod electric furnace of 300 kilos. capacity gave a matte with 4.9% Ni, 4.1% Cu, 30.5% S, and 60% Fe, and a ferro-nickel with 13.8% Ni, 0.72% Cu, 8.37% Si, 1.32% S, and 75% Fe. A recovery of 91.3% of the total nickel and 77.4% of the total copper in the original ore smelted was made in these separate products. Refining of the ferro-nickel to a degree sufficient to allow of its use in the manufacture of nickel-steel can be carried out without difficulty. The addition of 5% of iron scale and an equal quantity of lime suffices to reduce the sulphur contents to a harmless amount.—J. N. P.

Zinc ore; Hydrometallurgical and electrolytic treatment of——. E. E. Watts. Met. and Chem. Eng., 1917, 16, 645—647.

THE author has made tests to ascertain how metallic zinc can be obtained continuously by electrolysis of a zinc sulphate solution with the addition of high-grade zinc products at the anode. Sulphurous acid or zinc sulphite prevents successful electrolysis, so that the product from sulphurous acid leaching of a zinc ore cannot be used without first being roasted. Any of the various forms of zinc oxide may be used successfully if added in separate anode compartments. The anodes were lead or antimony lead, the cathodes copper or aluminium, the current density from 2.5 to 4.5 amps. per sq. dem., and the voltage 3.5 to 6 volts. The process was operated on a small commercial scale with canvas diaphragms, and although it did not show a satisfactory profit, it appears to be workable if the diaphragm material can be satisfactorily improved.—W. H. P.

Condenser tube corrosion. W. Ramsay. Engineering, 1917, 104, 41—46.

THE corrosion of brass is due to local electrolytic action through non-homogeneity, which occurs in all alloys, e.g., at the junction of the crystals. In condenser tubes, corrosion is usually accompanied by the solution of the zinc, leaving the copper or material rich in copper as a coherent film, the original dimensions of the tube being nearly preserved. In the case of alloys of 60% Cu and 40% Zn, the action takes place between the α and β constituents and may proceed to completion, leaving a product which, on microscopical examination, is seen to consist of a material of the appearance of copper, which preserves the form of the α constituent, the space previously occupied

by the β being more or less filled by a corrosion product or possibly empty. With tubes of brass containing 70% Cu and 30% Zn, and Admiralty alloy, the corrosion appears to be accompanied by the formation of a more or less continuous film of copper on the surface; electrolysis then takes place between the copper and the underlying adjacent brass, resulting in a gradual concentration of copper. With these tubes the removal of zinc is as a rule superficial, the more compact nature of the residual copper sealing off the metal underneath from further action. The higher resistance of lead brass is also probably due to formation of a more insoluble corrosion product on the porous copper residue. There is evidence that the removal of zinc is accompanied by the solution of copper, which is re-deposited on the brass, an equivalent amount of zinc going into solution. Most copper compounds are capable of depositing metallic copper on brass. On painting tubes with basic chlorides of zinc and immersing them in warm sea water, a distinct copper-coloured stain results after some time. Defects sometimes appear on the inside of tubes in the form of laminations, which may often be traced for a number of feet; these arise from fissures or spills formed during the casting and elongated during the drawing. On opening up, these defects, which may occur as mere surface folds or may penetrate the wall of the tube to some extent, are seen to be coated with copper oxide which on immersion in sea water is gradually reduced to the metallic state, and this is probably the initial stage of electrolytic corrosion. In other cases, the interiors of tubes become pitted along the bottom through the settling of particles of iron which set up a local galvanic action accompanied by the deposition of ferric hydroxide along the tube. Metals which are electro-positive to brass, such as iron, zinc and lead, and carbon were found to initiate corrosion, probably through secondary action due to copper being re-deposited on the foreign metal. A corrosion which attacks the inlet ends for a few inches immediately beyond the tube plate was traced to the deposition of dissolved gases from the circulating cold water at the point where it becomes warm. This defect occurs where a smaller volume of steam is used, and owing to reduced circulation, the friction of the water is insufficient to sweep away the deposited gases; it is more marked when use is made of contaminated water, containing large amounts of carbon dioxide and ammonia. The extreme ends of the tubes are in some cases eaten away on account of the changed physical condition produced by crushing or distortion in the ferrule. Tubes which have been grooved corrode frequently in the locality of the furrows through overstrain during the grooving, and this defect could probably be remedied by annealing after finishing. The direction of the flow of current between hard and soft brass in an electrolyte varies in a very erratic manner, which is apparently due to polarisation and the condition of the electrode surface. The difference of potential in the cold is usually about 2.5 to 5 millivolts, and is increased by bubbling air or carbon dioxide through the electrolyte, but unless fresh electrolyte is continuously supplied the current falls off very rapidly. The small currents involved cannot immediately have a corrosive effect, but when the conditions are favourable, as in a condenser, where the galvanic elements are in close metallic continuity and the resistance and polarisation low, the time factor becomes important. The E.M.F. from copper-brass is appreciably higher and becomes of significance in the consideration of electrolysis between brass and metal from which zinc has been dissolved. For some unknown reason, tubes, after several years of service, have been found practically unaffected except for dirt and slight oxidation, though such tubes respond to artificial corrosion

tests as readily as normal tubes. Tinning the metal, if well carried out, seems to increase the life in some cases, while in others it appears to accelerate the breakdown. Zinc and iron protectors have a slightly favourable influence on the life of the tubes. The corrosion of brass is more marked the higher the content of zinc and would appear to be best obviated by the substitution of more resistant alloys, such as cupro-nickel, for the manufacture of condenser tubes.—J. N. P.

Metal colouring. I. "Shakudo." II. New kind of "shakudo," and "shibuichi." S. Miyasawa. *Kogyo-Kwagaku-Zasshi* (J. Chem. Inds. Tokyo), 1917, 20, 109—134, 365—384.

SHAKUDO is an alloy consisting essentially of copper and gold, which is used in Japan for the manufacture of objects of art and is coloured by treatment with aqueous solutions containing copper sulphate and acetate. The author's experiments show that the coloration is due to the production of a layer of cupric oxide, the tint being determined by the thickness of the layer. The colouring solution contains hydrogen ions owing to hydrolysis of the copper salt, and when the alloy is introduced a local electrical circuit is formed between the gold and copper, the latter being dissolved as cupric ion and hydrogen ions being discharged, thus disturbing the equilibrium. In consequence of this, hydrolysis proceeds further, and the process goes on, with progressive increase of the concentration of cupric and hydroxyl ions, until the solubility product of cupric hydroxide is exceeded. The precipitated hydroxide is rapidly converted into the oxide, which is deposited on the surface of the alloy. An analogous coloration can be obtained on alloys containing palladium, platinum, and silver, respectively, in place of gold.

In confirmation of these views as to the mechanism of the coloration of shakudo, it is shown that a similar effect is produced by mere contact of copper with platinum, palladium, or gold in the solution used, and that an electric current is produced when a copper electrode is connected by a copper wire with a platinum or palladium electrode immersed in acid or in the salt solution used for colouring shakudo. The colouring of "shibuichi," an alloy of 25% of silver and 75% of copper, used for purposes similar to those mentioned for shakudo, is due to an analogous cause.

Iodimetry; Differential—, IV. Analysis of pyrolusite and other oxidised manganese ores. O. L. Barnebey and G. M. Bishop. *J. Amer. Chem. Soc.*, 1917, 39, 1235—1238.

THE method described previously (this J., 1917, 571) is not generally applicable because certain ores are decomposed only with difficulty by treatment with phosphoric acid and potassium iodide. Another method is now described based on the facts that whereas both ferric iron and manganese dioxide liberate iodine from potassium iodide in presence of hydrochloric acid, yet if the resulting solution be subsequently neutralised, only the ferrous iron is oxidised by the iodine, the manganese remaining in the divalent condition. To determine the available oxygen in pyrolusite (which practically always contains ferric iron), 0.2 gm. of the sample, powdered to pass a 200-mesh sieve and dried at 110° C., is treated with 10 c.c. of N/1 sodium iodide and 5 c.c. of concentrated hydrochloric acid, and the mixture allowed to stand, with frequent shaking, in a covered flask. When the reaction is complete, 0.2—0.5 gm. of sodium tartrate (to prevent hydrolysis of the iron salt) is added, the solution is diluted to 150 c.c., neutralised with sodium bicarbonate, and excess of the bicarbonate added.

The free iodine (equivalent to the manganese dioxide present in the sample) is titrated with arsenite solution, using starch as indicator.

Mercury; [*Laboratory*] apparatus for the purification of—. H. E. Patten and G. H. Mains. J. Ind. Eng. Chem., 1917, 9, 600—603.

THE apparatus combines the spraying of the mercury through a column of dilute nitric acid, with the automatic return and circulation of the mercury, electrolytic purification, and the automatic renewal of the nitric acid to remove products of the electrolysis and prevent impurities from being redissolved. The impure mercury flows from a main reservoir, through a stopcock, into a spraying chamber, and falls on to a piece of bolting silk stretched across the lower end of the chamber. The mercury passes through this, and is broken up into a fine spray as it enters the column of nitric acid. A platinum wire is fused through the side of the spraying chamber into a mercury contact cup, and this wire extends down to the mercury on the silk, which thus becomes the anode. The spraying chamber is fitted into the ground glass neck of a fall tube, a slot being provided in the neck for the introduction of the cathode wire into the tube. Just below the level of the electrode is an overflow tube through which the products of the electrolysis are withdrawn by means of a stream of dilute (2%) acid, which is introduced into the lower end of the fall tube from an acid reservoir at the rate of about 1000 c.c. during a run of 7 hours. Connected with the bottom of the fall tube is an injector constructed on the principle of the Sprengel pump, whereby the mercury is raised in small globules in a current of air through a tube of small bore to an auxiliary reservoir at the top of the apparatus. The inner tube of this device is connected with the laboratory vacuum system, whilst the tube through which the mercury is raised is surrounded by a heating coil to promote the oxidation of foreign metals in the mercury. The mercury then flows back into the main reservoir through a tube provided with a stopcock. The flow of mercury through the apparatus is regulated at about 30 c.c. per min., and during a period of 7 hours the metal circulates about 100 times through the acid. After circulating about 300 times it is drawn off through an outlet at the bottom of the fall tube. Mercury thus purified has given satisfactory results in thermo-regulators and in calomel half-cells. Any trace of nitric acid may be removed by distilling the mercury once with air bubbling through it as in Hulett's method (Phys. Rev., 1905, 21, 388), and then redistilling it *in vacuo*. About 7% of the mercury is lost by solution in the nitric acid, but upwards of 75% of this dissolved mercury may be recovered as calomel.—C. A. M.

Cerium-iron alloys. R. Vogel. Z. anorg. Chem., 1917, 99, 25—49. J. Chem. Soc., 1917, 112, ii, 259.

THE alloys were prepared in quantities of 20 grms in special porcelain tubes, the cerium used containing 95.6% Ce, with lanthanum and traces of iron, but free from neodymium and praseodymium. Nitrogen was used to protect against oxidation. Cerium of this degree of purity solidifies at 775° C. The solidif. point curve falls to a eutectic point at 335° C. and 5% of iron. The rising branch of the curve corresponds to the separation of a compound, $CeFe_2$, which is changed at 773° C. to the compound Ce_2Fe_3 . There is a second break in the curve at 1085° C., where Ce_2Fe_3 breaks up into liquid and a solid solution rich in iron. This solid solution contains up to 15% of cerium at 1085° C., diminishing on cooling to about 11% at 850° C. and lower temperatures. It undergoes two polymorphic changes due to those of iron, at

810° C., determined thermally, and again at 795° C., recognised by the appearance of magnetic properties on cooling. The change in saturation of the solid solution at these points, if any, is too small to be observed. Cerium, $CeFe_2$, and Ce_2Fe_3 do not form solid solutions. The reactions in the solid state take place slowly, and there is difficulty in obtaining equilibrium. The compound $CeFe_2$ is magnetic at the ordinary temperature, but becomes non-magnetic at 116° C. It is uncertain how far the second compound is magnetic, as the alloys contain the magnetic solid solution, which becomes non-magnetic at 795° C. The hardness is a maximum at 60% of cerium. The saturated solid solution is more resistant to oxidation than pure iron. The compounds are readily oxidisable, especially $CeFe_2$. The pyrophoric properties reach a maximum at 70% of cerium, and depend on the presence of one or other of the compounds. Pyrophoric cerium alloys usually consist of a hard compound embedded in a softer, readily oxidisable ground-mass.

Metallic coatings prepared by the spraying method: Structure of—. H. Arnold. Z. anorg. Chem., 1917, 99, 67—72. J. Chem. Soc., 1917, 112, ii, 260.

COATINGS prepared by Schoop's method of melting the end of a rod of metal and converting the molten drops immediately into spray by the action of a blast of air have been examined microscopically. Such coatings may be obtained in an adherent form even on paper or celluloid. The molten drops are elongated during their flight through the air, so that each has a long tail. The coatings have a fine waved or laminated structure, which is characteristic, and enables them to be distinguished from coatings obtained electrolytically or by other methods. The laminae are due to the flattening out of the drops on reaching the surface. The union of the particles is a mechanical one, the fibres being felted together, and the evidence does not point to the formation of a true weld. Thus, successive spraying with zinc and copper leaves the two metals separate, and brass is not formed.

Silicon-coated metal. W. E. Vawter. J. Ind. Eng. Chem., 1917, 9, 580—581.

SAMPLES of iron wire were heated at temperatures ranging from 500° to 700° C. in a current of dry silicon hydride for varying periods up to 7 hours. In some cases a homogeneous coating of silicon was obtained, but, at best, only a thin fragile layer was deposited, which had a tendency to scale off. Preliminary treatment of the iron by pickling in acid and exposure to the air before heating gave no better results. In the case of other metals, including copper, nickel, and aluminium, no coating of any kind was obtained.

—C. A. M.

Sulphur chloride: Reaction of— with metals. Catalytic action of ether. N. Domanicki. J. Russ. Phys.-Chem. Soc., 1916, 48, 1721—1727.

PREVIOUS investigators have shown that some metals do not react with sulphur chloride either in the cold or on heating, whilst others react only on heating, and in a few cases the reaction begins at the ordinary temperature: the products of the reaction are sulphur and chlorides of the metals, with small proportions of sulphur compounds. The author finds that the reaction may be brought about or greatly accelerated by the agency of dry ether, with which the metallic chlorides form complexes and so enhance the thermal effect of the reaction. Under these conditions, magnesium, zinc, aluminium, tin, antimony, bismuth, molybdenum, iron, mercury, and gold are readily converted into their chlorides or etherates of the latter. On the other hand, the alkali metals,

calcium, cadmium, thallium, lead, tungsten, chromium, manganese, cobalt, nickel, copper, silver, and platinum, react either not at all or with extreme slowness. The metals which do react either (1) give chlorides which readily form etherates, as is the case with zinc, aluminium, tin, and bismuth, or (2) give chlorides which are readily fusible and volatile and approximate in their properties to the chloro-anhydrides; in correspondence with the latter, the higher chlorides are mostly formed, for instance, $ZnCl_2$, $FeCl_3$, $HgCl_2$. Univalent metals do not react and divalent metals—excepting mercury—if at all, react with far greater difficulty than trivalent and quadrivalent metals. It is probable that other metals, giving volatile higher chlorides, such as titanium, germanium, vanadium, and the like, would also react readily with sulphur chloride and ether.—T. H. P.

PATENTS.

Cast-iron; Production of—S. Wallis, Darlaston, Staffs., J. S. Cudlip, Beeston, Notts., A. Parr, West Bridgford, Notts., and J. B. Cudlip, London. Eng. Pat. 106,196, Aug. 2, 1916. (Appl. No. 10,926 of 1916.)

CAST-IRON containing about 1.88% of silicon, 2.25% of graphitic and 0.67% of combined carbon, is produced by melting a mixture of 1 part of hot-blast pig iron, 3 of cold-blast pig iron low in silicon, 2 of the same of medium silicon content, and 4 of scrap iron. Mild steel (7 lb.) and aluminium (3 lb. per 10 cwt. of cast-iron) may also be added. —W. R. S.

[Cobalt-chromium] steel. P. R. Kuehnrich, Sheffield. Eng. Pat. 106,187, July 25, 1916. (Appl. No. 10,433 of 1916.)

THE steel contains carbon 1—3.5, chromium 6—20, and cobalt 1—6%. Small quantities (up to 1%) of nickel, molybdenum, tantalum, or vanadium may be added. The steel possesses the characteristic properties of high-speed steels, but melts at a lower temperature than tungsten high-speed steel, and can be hardened at a much lower temperature than is necessary with ordinary high-speed steels. —W. R. S.

Steel; Method and means for annealing — J. G. R. Munday, Kingston-upon-Hull. Eng. Pat. 106,624, Aug. 17, 1916. (Appl. No. 2365 of 1916.)

THE steel is heated, e.g., to 600°—700° C. for high-speed or air-hardened steel, and is then placed in a liquid annealing mixture of turpentine (1 gall.) and resin (1 lb.); common salt (2 lb.) and sulphur (1½ lb.) may be added to the mixture.—W. R. S.

[Steel] casting process and apparatus therefor. J. C. Davis, Hinsdale, Ill., U.S.A. Eng. Pat. 106,678, June 1, 1916. (Appl. No. 7805 of 1916.)

THE casting is made by mixing a modifying element (such as manganese) in suitable proportion with a uniform column of molten metal immediately prior to its entry into the mould. The flow of molten metal is controlled by a "choke device," and the modifying element is forced into the stream of metal between the "choke device" and the mould; valves connected for simultaneous operation control the flow of the two metals. The mould may be rotated, and the metal and modifying element brought together in gradually changing

proportions so as to produce a casting of varying composition from the periphery of the casting inwards.—W. R. S.

Manganese-steel; Manufacture of — for railway wheels. R. Schwarz, Vienna. Ger. Pat. 297,509, Oct. 5, 1915.

STEEL with about 1% carbon and 17% or more of manganese can be so tempered that it is equal in tensile properties and resistance to shock and wear to the well-known steels with about 1% carbon and 12% manganese, but in addition has a greater resistance at higher temperatures and so is particularly suited for railway wheels where heating occurs through impact and the action of brakes. Tempering is effected by heating to about 1000°—1100° C., and cooling by an air current or by a cooling liquid at a speed greater than that of ordinary air cooling but less than that produced by quenching in the usual way.—J. N. P.

Decaridation of mild steel, steel, or copper. H. König, Crefeld. Ger. Pat. 297,411, May 12, 1916. Addition to Ger. Pat. 290,309 (this J., 1916, 511).

THE process described in the chief patent (*loc. cit.*) is modified in that the carbon anode is made to dip into the bath of molten metal, whilst the cathode, which may be of carbon or other suitable material, is not in contact with the bath so that an arc is struck between it and the surface of the molten metal.—J. N. P.

Ores; Process for separation of — [by flotation]. E. Primosigh, Also-Szalank, Hungary. Eng. Pat. 29,340, Dec. 19, 1913.

AFTER crushing, the material is sifted with a sieve containing 130 meshes per linear inch. The fine portion is subjected to an intermittent flotation process in which the metallic particles are removed with the foam from a water, acid, and oil mixture flowing continuously away from the apparatus, accompanied by the minimum amount of liquid (see Eng. Pat. 10,087 of 1914; this J., 1917, 721). A duration of 3 to 4 hours may be required for the operation. The granular portion of the ore can be satisfactorily treated by a continuous flotation process.—J. N. P.

Flotation of minerals. H. P. Corliss, Pittsburgh, Pa., Assignor to Metals Recovery Co., New York. U.S. Pats. (A) 1,228,183 and (B) 1,228,184, May 29, 1917. Date of appl., Mar. 21, 1917.

THE pulp is subjected to a flotation process in presence of a small amount of (A) α -naphthylamine or (B) nitronaphthalene, with or without addition of an oil.—W. R. S.

Ore concentrator or separator. W. H. Munroe, Assignor to G. A. Mattison and A. B. Conklin, Ashland, Ala. U.S. Pat. 1,230,081, June 12, 1917. Date of appl., Oct. 10, 1916.

AN open tank for the concentration of ores by flotation has curved walls elongated at the base so as to form a V-shaped trough. By means of a curved plate a stream of liquid is caused to flow across and in line with the upper surface of the liquid in the tank, and the ore is fed, in a thin layer, into the path of the entering liquid. The feed of liquid causes the body of liquid in the tank to rotate in a direction opposite to that of the hands of a clock.—J. N. P.

Mixer [for flotation process]. G. A. Williams, Lark, Utah. U.S. Pat. 1,230,638, June 19, 1917. Date of appl., May 23, 1916.

A TALL cylindrical vessel with a conical base is fitted inside with a smaller concentric vessel of the same form. The two vessels communicate at the

top and the space between them contains an oil and water flotation medium which is admitted to a definite height. An inlet pipe is connected with the base of the outer cylinder, and a separate outlet pipe with the base of the inner cylinder. Streams of air are admitted to the liquid in the outer space by means of jets near the base, and the inner vessel is provided with a series of agitators which are arranged to rotate on the same vertical shaft below fixed conical deflectors. A circulation of the liquid upwards from the outer to the inner vessel, carrying with it the material under treatment by flotation action, takes place through the lower specific gravity of the aerated liquid.—J. N. P.

Zinc; Production of metallic—A. J. F. de Bavay, Kew, Victoria, Australia. Eng. Pat. 102,142, Oct. 17, 1916. (Appl. No. 14,760 of 1916.) Under Int. Conv., Nov. 6, 1915.

Zinc is distilled from ore in a suitable furnace and the vapour, after passing through a flue filled with incandescent coke, or the like, to reduce any zinc oxide, passes into a condenser consisting of a long chamber divided into a number of compartments by cross-baffles or bridges projecting upwards from the bottom and sub-divided by other baffles depending from the top. A bath of molten zinc is maintained in the separate compartments, and by means of the depending baffles which extend below the surface of the zinc, the fumes caused to pass through a layer of the molten metal in its passage from one division to the other. The bridges are formed with a groove, the near side lip being made slightly lower than the far side lip, and the groove is connected to a pipe which projects downwards and dips into a vessel containing a body of molten zinc of sufficient depth to counterbalance the pressure in the condenser. A constant level of the bath of molten zinc is thus maintained within the compartments, the surplus zinc being withdrawn from time to time. Each compartment is further provided with a well having a plugged outlet by which the molten zinc may be tapped at the end of the operation. The last compartment is provided with an outlet flue leading to a chamber, to which an exhaust fan is connected. The separate compartments are heated and the temperature of the chambers falls progressively throughout the series. Lead and the least volatile impurities in the fume are thus condensed in the first chamber while cadmium and more volatile metals escape uncondensed with the exit gases from the last compartment which collects the purest zinc. For the refining of spelter the first compartment of the condenser may be adapted for the distillation of the zinc by admitting the metal in molten form from a suitable crucible. For this purpose, the first compartment is maintained at 900° C., the second at about 650°, and the third at about 450° C.

—J. N. P.

Furnace; Zinc smelting—J. W. and H. Hegeler, Assignors to The Hegeler Zinc Co., Danville, Ill. U.S. Pat. 1,227,050, May 22, 1917. Date of appl., Nov. 17, 1913.

NE of the walls of the furnace is provided with a framework, comprising metal supports and transverse metal bars supported by and extending between the supports, and is practically non-retractible by heat, whilst the other wall, of clay, contracts excessively and permanently under heat. The roof is formed from sections supported by the framework and by the fire-ay wall, and is in tilting and sliding engagement respectively with these walls.—B. N.

etal; Stirring molten—[in electric furnaces, etc.], E. Stassano, Turin, Italy. Eng. Pat. 106,313, May 15, 1916. (Appl. No. 6496 of 1916.)

IRRING is effected by imparting rotational move-

ment to the molten metal by means of a rotary magnetic field, electromagnetic cores being arranged on or in the casing of the chamber containing the molten metal and excited by a current controlled by a commutator, by means of which the current is periodically interrupted and the direction of rotation of the magnetic field reversed. The electromagnetic cores may be mounted on a support independent of the chamber containing the molten metal, and the chamber introduced within the support when stirring is required.

—J. N. P.

Open hearth regenerative furnaces, The Clyde Furnace Co. (A), Ltd., and W. Dixon, Glasgow. Eng. Pat. 106,376, Aug. 17, 1916. (Appl. No. 11,644 of 1916.)

THE lining is repaired whilst the furnace is in operation, by fitting at the damaged part a metal plate or fireclay slab and filling in plastic refractory material at the back thereof. The repairing material solidifies before the plate or slab is burnt away.—W. R. S.

Crucible or melting furnaces fired by solid fuel. I. Hall, Birmingham, Eng. Pat. 106,896, July 18, 1916. (Appl. No. 10,057 of 1916.)

IN a crucible furnace for use with solid fuel, the outer furnace casing is enlarged at the lower part so as to form, in conjunction with the lining, an annular blast or air chamber, into which air, under a pressure of, for instance, 6 inches of water, is introduced. The fuel is supported on a grate below the crucible, the grate preferably being constructed in halves. Air from the annular blast chamber is supplied through ducts to the space below the grate, and also, through another series of ducts, to the interior of the furnace above the grate. Inspection holes are formed in the outer casing opposite this second series of ducts and are provided with sliding covers.—J. N. P.

Furnace; Heat-treating—T. F. Bailly and F. T. Cope, Assignors to The Electric Furnace Co., Alliance, Ohio. U.S. Pat. 1,227,027, May 22, 1917. Date of appl., May 13, 1915.

THE furnace is provided with a heating chamber, having inlet and outlet openings on opposite sides and doors arranged normally to cover the openings, mechanical means being arranged to pass the material to be treated through the chamber, and similar means for opening and closing the doors. A thermally-controlled device, for measuring the temperature of the furnace, is located within the heating chamber, and an electrical controlling means is provided to form an operative connection between the temperature-measuring device and both the mechanical means.—B. N.

Metal-melting furnace, D. S. Marfield, Assignor to The Buckeye Products Co., Cincinnati, Ohio. U.S. Pat. 1,229,494, June 12, 1917. Date of appl., Jan. 2, 1917.

A ROTATING cylindrical furnace, lined with refractory material, is mounted horizontally on bearings. A horizontal blowpipe with ports for gas and air passes through one of the bearings, and a charging and pouring port for the metal leads through the wall of the chamber at right angles to the axis of rotation. The charging port at its inner end has an annulus projecting for a short distance inside the chamber and adapted to baffle the combustible gases as they sweep along the wall of the chamber towards the port.—J. N. P.

Aluminium; Process for obtaining by a cold process a galvanic deposit of—E. L. Lalbin, Paris. Eng. Pat. 106,400, Sept. 23, 1916. (Appl. No. 13,523 of 1916.)

ALUMINIUM chloride, dissolved in a liquid hydro-

carbon such as toluene, etc., is electrolysed, the liquid being rendered conductive by the addition of "potassium bitfluoride."—B. N.

Aluminium-soldering flux. H. V. Burt, Rock Island, Ill. U.S. Pat. 1,225,761, May 15, 1917. Date of appl., Mar. 2, 1916.

THE flux contains: oleic acid 90, and spirit of ammonia 8 parts.—W. R. S.

Aluminium alloy, and articles made therefrom. A. W. Morris, Springfield, Mass. U.S. Pat. 1,227,174, May 22, 1917. Date of appl., Nov. 26, 1915.

THE alloy contains not less than 70% of aluminium, together with 1—6% of iron, and one or more other hardening metals such as nickel.—J. N. P.

Aluminium skimmings, screenings, dross, slags, or analogous aluminous materials; Process for treating —. S. W. Lawrie, Milwaukee, Wis. Assignor to W. F. Jobbins, Inc., Aurora, Ill. U.S. Pat. 1,228,119, May 29, 1917. Date of appl., Sept. 8, 1913.

THE material is treated with a solution of alkali so as to produce an aluminate solution from which zinc, copper, and other impurities are precipitated as sulphides. The metals may be extracted from the sulphide precipitate.—J. N. P.

"Bronzing" or colouring of metallic surfaces [; Electrolytic] —. Q. Sestini and T. Rondelli, Bergamo, Italy. Eng. Pat. 106,774, Nov. 18, 1916. (Appl. No. 16,582 of 1916.)

A COLOURED protective layer is formed on a metallic surface by covering it with a deposit of electrolytic iron or copper which is subsequently oxidised. The article to be coated is, without preliminary cleaning, arranged as cathode in a strongly alkaline solution, heated to 120°—140° C., while the anode consists of iron or copper, and a current of about 5 amps. per sq. dm. is passed for 1 to 2 mins., when the surface is at the same time cleaned and coated with metal. The current is then passed in the reverse direction for 6 to 8 mins., when the metallic deposit previously formed is oxidised, the completion of the oxidation being shown by the change of voltage, which rises from about 0.6 to between 1.8 to 2 volts. The alternate deposition and oxidation may be repeated several times, ending finally with an oxidation, by arranging the article as anode. The deposit is strengthened and rendered more adhesive by subsequently immersing for a few minutes in a solution of sodium hydroxide of sp. gr. 1.1 and containing 10—20% of sodium nitrate, nitrophenol, or nitronaphthol, and heated to about 140° C. After drying, the article is immersed for 10 mins. in a bath of olive oil heated to 150—180° C. The colour and brightness of the deposit are determined by the electrolyte employed and the number of alternations of the electrolysis.—J. N. P.

Electric heating and tempering [of metals]; Apparatus for —. The Sneed and Co. Iron Works, Jersey City, N.J., U.S.A., Assignees of H. P. Macdonald, Montclair, N.J., and E. M. Huggins, New York. Eng. Pat. 106,940, Nov. 3, 1916. (Appl. No. 15,733 of 1916.) Under Int. Conv., June 14, 1916.

METAL tubes or the like to be tempered or annealed are held vertically by two pairs of jaws which make contact at the two ends and serve as terminals for the passage of an electric current through the tube. The lower pair of jaws is mounted on a movable support, which is forced downwards as the tube expands on heating. After a predetermined degree of expansion,

corresponding to the desired temperature, has been reached, a trip lever is released by the movable support which permits a counterweight to open a switch cutting off the supply of current and at the same time opening the supporting jaws and allowing the metal to fall into a quenching liquid.—J. N. P.

Cementation compound. J. M. Allen, J. C. Christen, and O. S. Miller, St. Louis, Mo. U.S. Pat. 1,226,739, May 22, 1917. Date of appl., Sep. 15, 1916.

A FINELY-DIVIDED mixture of equal weights (30—32%) of anthracite coal, bones, and carbonaceous matter, together with from 4—10% by weight of manganese.—J. N. P.

Carburising agent. L. Dankmeyer, Königsberg, Ger. Pat. 297,244, May 5, 1915.

THE claim is for coating materials used for carburising iron with a mixture of lime, gypsum, sodium silicate, or the like. On adding the material to molten iron, the covering layer melts, forming a slag which protects the carbon against oxidation and causes its solution in the metal to proceed slowly.—J. N. P.

Ores; Apparatus for roasting —. G. L. Tanzer, Seattle, Wash. U.S. Pat. 1,226,923, May 22, 1917. Date of appl., Mar. 25, 1915.

A ROTARY furnace is provided with hollow trunnions, and with a pump for moving fluid to and fro from end to end of the furnace, means being arranged to operate the pump and rotate the furnace simultaneously. The pump is composed of a cylinder with a solid piston reciprocating between its ends, and each end of the cylinder is connected by means of a pipe and swivel with one of the hollow trunnions.—B. N.

Metal-bearing substances; Process of reducing —. G. L. Fogler, Pittsburgh, Pa. U.S. Pat. 1,227,127, May 22, 1917. Date of appl., Mar. 30, 1912.

A CHARGE containing a metal (iron-) bearing substance is subjected to partial reduction in a furnace in the presence of felspar and insufficient carbon to complete the reduction, whereby a spongy mass is obtained by the solution in the molten slag of the partially reduced iron oxide. The product is then transferred to a second furnace together with carbon, when complete reduction is brought about and the iron separates in the fused condition from the slag.—J. N. P.

Dehydrator [for ore pulp]. C. Robinson, Mount Vernon, N.Y., Assignor to Metallurgical Engineering and Process Corporation, U.S. Pat. 1,227,491, May 22, 1917. Date of appl., July 21, 1913. Renewed Oct. 10, 1916.

A FILTERING drum into which the ore pulp to be dehydrated can be admitted is enclosed by a containing vessel and arranged to rotate in a vertical plane. The liquid collecting in the container can be raised from gutters at either side and fed directly on to the surface of the drum.—J. N. P.

German-silver alloy products and manufacture of same. R. Beck, Assignor to Dürener Metallwerke Akt.-Ges., Düren, Germany. U.S. Pat. 1,227,569, May 29, 1917. Date of appl., June 27, 1914.

THE alloy consists of zinc 40—50, nickel 5—15%, and at least one of the following: cobalt, manganese, iron, aluminium, tin, magnesium, or lead, the nickel predominating among these metals and the remainder consisting mainly of copper. The alloy is heated to redness, and rolled, drawn, extruded, stamped, or forged, while hot.—W. R. S.

Casings; Method of making —. W. A. Bole, Pittsburgh, Pa. U.S. Pat. 1,227,573, May 29, 1917. Date of appl., Sept. 25, 1912. Renewed, Apr. 12, 1917.

ABSORPTION of oxygen by the molten metal during casting is prevented by filling the mould with and submerging the pouring hole in an atmosphere of heavy inert dry gaseous products of combustion while pouring the molten metal.—W. R. S.

Copper-lead [manganese] alloy. E. D. Gleason, Asbury Park, N.J., Assignor to Neu-Metals and Process Co., Brooklyn, N.Y. U.S. Pat. 1,228,017, May 29, 1917. Date of appl., May 17, 1915.

A COPPER-LEAD-MANGANESE alloy is prepared by adding to a molten bath of equal weights of lead and copper, a mixture of 3% of cryolite and 2% of manganese oxide, together with some carbon.—J. N. P.

Precious metals; Apparatus for recovering —. C. R. Rawdon and F. McCoole, St. Louis, Mo. U.S. Pat. 1,228,133, May 29, 1917. Date of appl., Dec. 18, 1916.

A TANK is provided at one end of the base with an inlet pipe, and at a higher level on the opposite side, with a discharge pipe. A perforated screen or diaphragm is disposed horizontally in a plane between the inlet and discharge. An endless belt fitted with buckets of porous fabric travels over the surface of the liquid circulating through the tank, so that the buckets dip slightly below the surface of the liquid and gather or skim the metal values. On emerging from the tank the liquid in the buckets is forced through the fabric by the application of pressure and the residue deposited at the head of the tank.—J. N. P.

Composite metal article. F. A. Fahrenwald, Cleveland, Ohio. (Dedicated to the public.) U.S. Pat. 1,228,194, May 29, 1917. Date of appl., May 31, 1916.

TUBES and other articles for use at temperatures up to 1000° C., which are ductile, mechanically strong, and resilient, are made of tungsten or molybdenum coated with a surface layer of gold or gold-palladium alloy.—J. N. P.

Manganese alloys; Making low carbon —. E. Humbert, Niagara Falls, N.Y. U.S. Pat. 1,228,925, June 5, 1917. Date of appl., Mar. 6, 1914.

COMMERCIAL ferro-manganese which contains about 6% of carbon is heated in contact with manganese oxide in an electric furnace to a temperature above 1700° C., until the carbon content is reduced to about 1% or less.—J. N. P.

Alloy. H. S. Cooper, Assignor to The Electro Metals Products Co., Cleveland, Ohio. U.S. Pat. 1,229,037, June 5, 1917. Date of appl., Aug. 14, 1915.

AN alloy for electrical contact purposes is composed of silver 70, palladium 25, and cobalt 5%.—W. R. S.

Welding process; Electric —. C. B. Auel, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,229,700, June 2, 1917. Date of appl., Dec. 10, 1914.

A THIN sheet or ribbon of oxidisable metal is prepared for welding, by forming a large number of relatively small indentations on one side over substantially the area to be welded, and thus producing a like number of relatively sharp projections upon its other side. The surface coating of oxide is thus broken up, without distorting or weakening the sheet or ribbon, and the treated surface is placed against another metal surface, and electric current and pressure applied.—B. N.

Metal article, and process of making same. C. H. Humphries, Kearney, N.J., Assignor to The Commercial Research Co., Long Island City, N.Y. U.S. Pat. 1,229,960, June 12, 1917. Date of appl., Sept. 28, 1914.

FINELY divided tungsten is agglomerated into a solid massive form by the use of a small amount of nickel as a binding material for the particles of tungsten. The resulting metal is dense, hard, and non-ductile, but sufficiently malleable to allow of swaging hot or cold.—J. N. P.

Ores or metal-bearing products; Process for treating —. F. A. Eustis, Milton, Mass. U.S. Pat. 1,230,143, June 19, 1917. Date of appl., May 8, 1916.

OXIDISED iron ore which contains one or more of the metals, nickel, cobalt, aluminium, or manganese, is heated in the dry condition in an atmosphere of sulphur dioxide so as to bring about intimate contact between the material and the gas. By this treatment a relatively small amount of iron and a relatively large amount of the other metals are rendered soluble. The ore is then leached with a suitable solvent heated to boiling, and the iron precipitated from the solution by continued boiling.—J. N. P.

Copper; Process for extraction of — from its ores. H. B. Slater, Los Angeles, Cal. U.S. Pat. 1,230,078, June 12, 1917. Date of appl., July 28, 1915.

ORE containing native copper together with calcite is leached with a solution of ferric chloride and either sodium or calcium chloride, whereby copper is dissolved and a portion of the iron is precipitated. The solution is separated from the ore, the copper precipitated by the addition of metallic iron, and the solution is then regenerated by free chlorine, and used for a further extraction.—J. N. P.

Bearing metals; Manufacture of white —. Maschinenbau-Anstalt Humboldt, Cöln-Kalk. Ger. Pat. 297,210, Oct. 10, 1915.

ABOUT 3% of calcium is alloyed with lead by introducing it below the surface of the molten metal, and small quantities (1–3%) of cadmium and of bismuth are subsequently added to the melt. The resulting alloy is claimed to be equal in value to the best white metal alloys of high tin content.

Bearing metals; Manufacture of white —. C. Hassler, Aalen. Ger. Pat. (A) 297,290, Feb. 2, 1916, and (B) 297,291, Mar. 14, 1916.

(A) AN alloy is first prepared from 56–62 parts of antimony, 40–32 parts of copper, and 4–6 parts of 30% silico-copper, and from this a second alloy is prepared containing 15–35% of the first alloy, the remainder consisting of equal parts of antimony and tin. The final alloy is prepared by melting together 85–65 parts of lead and 15–35 parts of the second alloy. (B) An alloy is prepared by melting together 70–80 parts of zinc, 2–6 parts of copper, and 18–24 parts of a tin alloy composed of Sn 84–80, Sb 11–12, and Cu 5–8 parts. From this first alloy a second alloy is prepared by fusing 7–12 parts of it with 55–65 parts of lead and 23–33 parts of the tin alloy mentioned above. This second alloy is used in the preparation of alloys containing more than 17% Pb for the production of white metal bearings.

Platinum; Separation of — by a dry process. H. Haedicke, Schladerm. Ger. Pat. 297,211, July 28, 1916.

POWDERED ore containing platinum, or platinumiferous sand, is passed between the discharge poles of a high-tension electric circuit, when the heating action of the sparks causes the platinum grains to fuse on to the metal of one of the pole pieces.

After acquiring a certain concentration of platinum the pole plate is removed and the platinum recovered by melting off the base metal.—J. N. P.

Ores; Drying of moist —. W. Buddäus, Charlottenburg, Ger. Pat. 297,380, June 25, 1916.

A METHOD particularly suited for the drying of finely divided ores consists in mixing the material with a calculated amount of low-grade fuel such as lignite, peat, or sawdust, and placing it on two superimposed grates in a furnace. The material on the upper grate is partially dried by the hot gases rising from the lower layer, which is dried by the heat produced by combustion of its contained fuel. The partially dried material is transferred from the upper to the lower grate. Ores already containing combustible matter, such as bituminous ores, are dried by combustion of the organic matter without addition of fuel.—J. N. P.

Crucible furnaces for melting brass and other metal; Coverings of —. P. J. Weston, Birmingham, Eng. Pat. 106,781, Dec. 5, 1916. (Appl. No. 17,157 of 1916.)

Castling metal; Means for —. I. Hall, Birmingham, Eng. Pat. 106,850, June 2, 1916. (Appl. No. 7830 of 1916.)

Ores; Treatment of —. A. H. Higgins, Assignor to Minerals Separation, Ltd., London, U.S. Pat. 1,227,615, May 29, 1917. Date of appl., Nov. 11, 1913.

SEE Eng. Pat. 27,323 of 1912; this J., 1914, 204.

Ores; Art of fusing —. R. P. Pietet, Paris, U.S. Pat. 1,230,431, June 19, 1917. Date of appl., Oct. 29, 1913. Renewed May 12, 1917.

SEE Fr. Pat. 461,895 of 1912; this J., 1914, 201.

Zinc; Process of producing pure —. H. Specketer, Griesheim, Germany, U.S. Pat. 1,231,083, June 26, 1917. Date of appl., Sept. 2, 1913.

SEE Fr. Pat. 461,905 of 1913; this J., 1914, 205.

Zinc and other similar metals; Apparatus for producing —. H. Specketer, Griesheim, Germany, U.S. Pat. 1,231,084, June 26, 1917. Date of appl., Jan. 29, 1915.

SEE Ger. Pat. 290,643 of 1914; this J., 1916, 611.

Means for discharging material from mechanical furnaces. Eng. Pat. 107,185. See I.

Combined furnaces and gas producers. Eng. Pat. 106,513. See 11A.

Ductile filament. U.S. Pat. 1,226,925. See 11B.

Method of processing aluminium skimmings, screenings, slags, or analogous materials. U.S. Pat. 1,229,611. See VII.

XI.—ELECTRO-CHEMISTRY.

Electrolytic migration; Phenomena of —. *Electrolysis of mixed solutions of alkali salts.* M. Van Laer, J. Chim. Phys., 1917, 15, 151—163.

THE insertion of a diaphragm between the walls of a vessel containing a liquid undergoing electrolysis with electrodes which are not attacked, causes notable changes of concentration in the two compartments. A solution of potassium or sodium hydroxide thus becomes more concentrated at the negative pole, and more dilute at the positive pole, while the converse relationship is obtained with an acid. The change in the concentration is determined by the transport numbers or the relation between the migration velocities of anion and cation, and also by diffusion and electrical endosmosis, which favour the migration of certain ions and retard those with an opposite electrical charge. The transport numbers are

again affected by temperature, and the diffusion and cataphoresis effects vary with the potential and with the current density. With sodium hydroxide, cataphoresis and increase of temperature both hinder the migration of the hydroxyl ion relatively to the sodium ion, thus increasing the concentration in the catholyte. The current yield in regard to this concentration increases with the current density up to a certain limiting value, when further increase of current density gives a relatively lower yield. The most favourable intensity of current varies with the concentration of the electrolyte. With 2.5 amps., at 15 volts potential between the electrodes, in 865 c.c. of 0.775 N sodium hydroxide solution, and a temperature of 17.5° C., after passing 10 amp.-hrs., an increase of concentration corresponding to a current yield of 35.7% was obtained. With an anolyte of sodium carbonate and a catholyte of sodium hydroxide a similar concentration of sodium hydroxide occurs at the cathode, while bicarbonate is formed at the anode and finally precipitates, and the resistance of the cell gradually increases and finally stops the electrolysis. By adding to the anolyte a soluble oxy-salt such as nitrate, sulphate, chlorate, or perchlorate, the increase of resistance can be avoided, while the migration of sodium ions to the catholyte is not hindered. In this way, at a temperature of 52° C., starting with an anode liquor of 3.3 N sodium hydroxide and a cathode liquor of saturated sodium carbonate, together with 100 grms. of sodium nitrate per litre, and a current of 10 amps. for 13 hours, a concentration of 11.3 N sodium hydroxide was obtained with a current yield of 42.6%. This method of electrolytic concentration also enables pure baryta to be prepared from witherite (BaCO₃), used in conjunction with barium nitrate.—J. N. P.

Overvoltage; The hydration of ions and metal —. E. Newbery, Chem. Soc. Trans., 1917, 111, 170—189.

THE overvoltages, cathodic and anodic, of a number of metals during deposition have been measured under varying conditions of time and current density, and also in the presence of colloids. Under these conditions, cathodic overvoltages are generally very low, less than 0.5 volt, but with iron, nickel, and cobalt they are very high. Anodic overvoltages are low, unless passivity occurs, and passivity, during metal deposition, has been observed with iron, nickel, and thallium. Metal overvoltages are due to the formation of hydrides, higher oxides, etc., on the electrode surfaces, and the cathodic compounds form solid solutions in the deposited metal, which are very dilute except in the cases of iron, nickel, and cobalt. The single potentials of iron, nickel, and cobalt have been re-determined, but accurate and reproducible values are obtained only in the absence of free hydrogen and metallic hydrides. The single potentials of these metals are changed by 0.06 to 0.13 volt by rapid motion of the metal electrode relative to the electrolyte, but those of other metals are affected to a much smaller degree by similar treatment. The ions H, OH, Fe, Ni, and Co are hydrated in aqueous solutions: the ions Cu, Ag, Zn, Cd, Hg, Tl, Pb, Sn, NH₄, Na, K, Cl, NO₃, and SO₄ are non-hydrated. Colloids are carried into a metal surface only by hydrated ions, and have no effect on overvoltage, and little or none on the nature of the deposited metal unless such ions take part in carrying the current. Previous determinations of the degree of hydration of ions, by observations of the change of concentration of a non-electrolyte present, have given incorrect values due to the transport of the non-electrolyte by the ions present, and also by the action of electrical endosmosis. (See also this J., 1916, 1265; 1917, 38, 145.)—B. N.

Electrical conductivity of porcelain mixtures and shale upon heating. Kinnison. See VIII.

PATENTS.

Furnaces; Electric —. T. H. Watson and Co., H. A. Greaves, and H. Etchells, Sheffield. Eng. Pat. 106,626, Mar. 1, 1916. (Appl. No. 3067 of 1916.)

THREE-PHASE currents are distributed so that the supply phases have balanced loads, by grouping three transformer secondary windings in "star" fashion, so that the two windings connected to the two upper electrodes or groups of electrodes of the furnace are identical in output and voltage. The voltage of the winding connected to the lower electrode, embedded in the hearth of the furnace as a resistor, is less than either of the other two, and is proportioned according to the resistance of the lower electrode, the voltage in this winding being varied to balance the loads on the supply phases when the currents through the upper electrodes are equal. In an alternative arrangement, with two-phase currents, both supply phases are loaded when either electrode carries current, the two upper electrodes being connected to the opposite ends of the transformer secondary winding supplied by one phase of the two-phase supply, whilst the lower electrode is connected to one terminal of the transformer secondary winding supplied by the other phase, the other terminal being connected to the middle point of the first-named transformer secondary winding. The secondary voltage between the terminals connected to the upper electrodes is twice (or less than twice if resistance be interposed in the bottom electrode) the voltage between the terminals in the other transformer secondary winding, whereby the loads on the two phases of primary supply are balanced when equal currents pass through each of the top electrodes.—B. N.

Furnace; Electric induction —. J. Funck, Charlottenburg, Germany. Assignor to The Gröndal Kjellin Co., Ltd., London. U.S. Pat. 1,226,764, May 22, 1917. Date of appl., Feb. 2, 1916.

THE hearth of an electric induction furnace is lined by placing the lining material around a templet, comprising several hollow metallic elements, with suitable reinforcements, arranged at the furnace hearth, so that the templet closely fits and entirely covers the inner surface of the lining material. The templet, which is provided with an enveloping sheath of asbestos, or similar material, is utilised for heating and consolidating the material to form the lining *in situ*, and finally the templet is fused to form the metal bath of the furnace.—B. N.

Discharge of molten products from a furnace or other apparatus; Means for [electrically] promoting the —. Furnace for making products electrically and means for facilitating discharge of the same. Furnace for electrically making products and means for heating discharged products. J. H. Reid, Newark, N.J., Assignor to Patents Process Co. U.S. Pats. (A) 1,227,067, (B) 1,227,068, and (C) 1,227,069, May 22, 1917. Dates of appl., (A) Dec. 28, 1914, (B) and (C) Aug. 12, 1915.

(A) A DISCHARGE duct, forming the tap-hole of the furnace, is arranged in line with a trough extending from the duct, and the molten material flowing from the tap-hole through the trough completes an electrical circuit between one electrode arranged entirely within the furnace, and a second electrode situated in the trough outside the furnace wall. (B) A closed receptacle, attached to a condenser, is provided with electrodes, and the means for bringing the electrodes and the receptacle into an electrical circuit. The resistance between the electrodes is altered by means con-

trolled by an arrangement actuated electrically, so that products having varying volatilising points can be recovered by uniformly inducing and maintaining selective temperatures in substances of progressively varying resistance. Suitable means are provided for supplying the material to be acted upon, and for separating and recovering the desired product during the operation. The fore-hearth is heated by an electric arc produced by an induced or secondary current between opposite electrodes, independently of the discharge opening, in order to maintain the product in a fluid condition at the point of discharge. (C) The apparatus described in the preceding abstract (B) is claimed for producing fluid products from solid carbonaceous substances.—B. N.

Electrodes; Manufacture of —. E. H. Becker, Washington, D.C., Assignor to Kinetic Electric Co., Norfolk, Va. U.S. Pat. 1,228,169, May 29, 1917. Date of appl., Sept. 27, 1916.

A SLURRY of finely-ground copper oxide is made with water containing a small amount of a temporary binder, and the slurry is vibrated in a mould until it forms a compact body with the particles interlocked. The clear liquid is separated and the vibration continued to unite the particles.—B. N.

Manganese depolarising compound; Non-hydrated moisture-containing —. C. Ellis, Montclair, N.J., Assignor to National Carbon Co., Long Island City, N.Y. U.S. Pat. 1,228,359, May 29, 1917. Date of appl., Oct. 23, 1915.

AN intimate mixture of graphite and artificial manganese dioxide free from acid and containing occluded moisture, is used as a depolarising agent for Leclanché batteries, the proportion of graphite being substantially less than that of the manganese dioxide.—B. N.

Storage battery plates; Wood separator for —. Separator for storage-battery plates. W. Morrison, Chicago, Ill., Assignor to Vesta Accumulator Co. U.S. Pats. (A) 1,228,368 and (B) 1,228,369, May 29, 1917. Dates of appl., (A) Nov. 11, 1916, and (B) Apr. 2, 1917.

(A) WOOD separators are treated with a solution of barium hydroxide, which is then converted into barium sulphate in the pores of the wood. (B) Strontium hydroxide is converted into sulphate in the pores of the separators.—B. N.

Storage-battery plates; Paste for — and process of making the same. Process of making pasted storage-battery plates. L. H. Flanders, Jenkintown, Pa. U.S. Pats. (A) 1,228,516 and (B) 1,228,547, June 5, 1917. Date of appl., Oct. 20, 1913.

(A) A NON-SETTING storage battery paste, of any desired lead content per unit volume, is made from "varying oxides of lead" by mixing with water to form a paste, and then mixing with sulphuric acid of strength adapted to preserve the required consistency of the paste; sufficient acid is used to produce lead sulphate in appropriate quantity for increasing the volume of the water paste to give a predetermined lead content per unit volume, whilst leaving sufficient oxide to react with sulphating material in order chemically to set the paste. (B) The paste, having a definite weight of lead per unit volume, is prepared from lead oxides of a definite density and known lead content, a portion of the oxide being converted into a quantity of lead sulphate appropriate to the ascertained density and lead content of the oxides used, and to the capacity required. The paste is applied to a grid and whilst still wet is sulphated to set it and then charged to produce material of the desired porosity.—B. N.

Storage-batteries; Negative-pole plate for — and process of making the same. W. G. S. Grant, Hamilton, Ontario, and L. H. Flanders, Jenkintown, Pa., Assignors to The Electric Storage Battery Co., Philadelphia, Pa. U.S. Pat. 1,228,551, June 5, 1917. Date of appl. Oct. 8, 1913.

THE plate, whilst the paste is still wet from the process of manufacture, is subjected to a prolonged soaking in dilute sulphuric acid, then reduced, and dried in a non-oxidising atmosphere. Coherent active material of pure lead is obtained, free from cracks and ready for discharge.—B. N.

Insulating material; Making — from basic magnesium carbonate and fibrous substances. K. Schmid, Assignor to "Lipsia" Chem. Fabr. A.-G., Muehl, Germany. U.S. Pat. 1,228,609, June 5, 1917. Date of appl. Nov. 9, 1916.

NORMAL magnesium carbonate is precipitated on a mass of fibrous substances suspended in a liquid containing magnesium hydroxide, by the action of ammonium carbonate. The liquid is filtered off, the mass dried and heated to convert the magnesium into basic magnesium carbonate; or a pasty mass of basic carbonate may be first formed and then added to the fibrous substances.—B. N.

Gas generator [electrolysis of water]. L. P. Seville, Providence, R.I. U.S. Pat. 1,230,803, June 19, 1917. Date of appl. Aug. 28, 1916.

HYDROGEN and oxygen are generated electrolytically, then cooled as they pass from the generator into separate containers, the condensed moisture being led back into the generator. A diaphragm is so arranged, containing chambers through which the gases pass on their way to their respective containers, that a predetermined difference of pressure on one side of the system causes the diaphragm to close the gas entrance to the opposite container, until a balancing pressure has again been raised on that side. By means of a body of water, the gases are automatically compressed to a pressure higher than that originally generated.—B. N.

Electric furnaces. J. W. Moffat, Toronto, Canada. Eng. Pat. 106,760, Oct. 11, 1916. (Appl. No. 14,466 of 1916.)

XII.—FATS; OILS; WAXES.

Menhaden oil fatty acids; Composition of —. E. Twitchell. J. Ind. Eng. Chem., 1917, 9, 581—584.

FURTHER determinations by the melting point method previously described (this J., 1914, 797) have shown that the solid fatty acids of menhaden oil contain myristic acid and stearic acid, but not arachidic acid. The latter was present in the products of the hydrogenation of the total fatty acids, having been produced by the addition of hydrogen to an unsaturated fatty acid with 20 atoms of carbon. The menhaden oil fatty acids

had therefore the following composition:—Palmitic acid, 22.7; myristic acid, 9.2; stearic acid, 1.8; unsaturated fatty acids with 16 carbon atoms, none; unsaturated fatty acids with 18 carbon atoms, 24.9; with 20 carbon atoms, 22.2; and with 22 carbon atoms, 20.2%. Fusion of the fatty acids with potassium hydroxide did not yield arachidic acid, and hence the fatty acid with 22 carbon atoms was not erucic acid, although, like that acid, it yielded behenic acid on hydrogenation. It is probably a more unsaturated acid, which is converted in the fusion into stearic or palmitic acid. This was confirmed by the depression of the m.p. of this fraction when melted with pure stearic and palmitic acids.—C. A. M.

Fats used in medicine; Oxidation values of —. G. Issoglio. Annali Chim. Appl., 1917, 7, 187—199.

THE method previously described (this J., 1916, 808) has been applied to the principal fats used in medicine, including olive, almond, and castor oils, lard, and cod liver oil, and to ointments, etc., containing fats. The general conclusion drawn is that oils for medicinal purposes, and benzoated lard should not have an oxidation value exceeding 10. In the case of expressed castor oils of different origin, free from alcohol, the acid values ranged from 7.52 to 18.23, and the oxidisability values from 0.85 to 3.18. Under the conditions of the determination 1 mgrm. of alcohol would reduce 1.738 c.c. of N/100 potassium permanganate solution. Although castor oil may show a high acid value it does not undergo the same decomposition as ordinary types of oil, and hence, even when old, may only contain a small quantity of the volatile aldehydic and ketonic products found in other oils. Codliver oil which is of a reddish or brownish-yellow colour ought not to be used for medicinal purposes, since it has almost invariably undergone some decomposition, as is shown by the high oxidation value. A high oxidation value of the fat in mercury ointment points to the use of a rancid fat in the preparation, whilst an abnormally high value indicates the presence of oil of turpentine.—C. A. M.

Fatty acids; Course of the reaction which takes place when higher unsaturated — are fused with potassium hydroxide. A. Eckert. Monatsh. Chem., 1917, 38, 1—10. J. Chem. Soc., 1917, 112, i, 317.

THE author has examined the action of molten potassium hydroxide on several dihydroxy- and monohydroxy-fatty acids with the following results: Dihydroxystearic acid when fused with 6 times its weight of potassium hydroxide, 3 times its weight of water, and 3/5ths its weight of potassium chlorate at 200°—220° C., for ten to twelve hours, yields pelargonic acid and azelaic acid. In the same way, dihydroxybehenic acid yields pelargonic acid and brassylic acid; sativic acid

yields azelaic acid, acetic acid, and hexoic acid. β -keto-stearic acid is practically unacted on. From these results the author draws the conclusion that dihydroxy-acids and monohydroxy-acids are not intermediate products in the decomposition of higher unsaturated fatty acids, and that the probable course of the reaction is to be regarded as the direct shifting of the double linking to the end of the chain.

Lipase; Activation of pancreatic — by cholate. J. A. de Jonge. Arch. Néerland. Physiol., 1917, 1, 182—197. J. Chem. Soc., 1917, 112, i, 36.

THE extent of activation of pancreatic lipase by sodium cholate depends on the age of the pancreatic extract and appears to vary rhythmically

as the age of the extract increases. A pancreatic extract, the activity of which is increased by the addition of sodium cholate, may at the end of a week have entirely lost the capacity for being thus activated. If this extract is kept for another week, the addition of cholate again begins to exert an activating action, and at the end of the second week the activation produced by the cholate may be greater than that observable with the original extract. At the end of the third week the activating capacity may have again vanished, and so on. The addition of gum arabic to the pancreatic extract produces an activating effect owing to its emulsifying action on the substrate, and this action is independent of the age of the pancreatic extract. The specific action of sodium cholate is therefore different from that of gum arabic; it is not concerned with the emulsification of the substrate, but with a true activation of the lipase.

Fuller's earth and its valuation for the oil industry.
T. G. Richert. J. Ind. Eng. Chem., 1917, 9, 599—600.

As it is not possible to determine the absolute bleaching power and absorptive capacity of fuller's earth, it is necessary to compare the results obtained with an unknown earth with those given under the same conditions by a sample already tested. From the results of laboratory determinations of loss of oil by absorption, and a knowledge of the loss by absorption in practice in the case of a particular earth, it is possible to calculate the presumptive loss with other earths under the same conditions. Assuming an earth will bleach an oil to a certain extent, the bleaching cost may be calculated by means of the formula—

$$V = \frac{x(100P + AO)}{100} \text{ cents,}$$

where x is the necessary % of earth, A the presumptive loss, and P and O the price in dollars for 100 lb. of earth and oil respectively. In practice the bleaching usually costs 25 to 50% less than is indicated by the calculation, since the effect is intensified by the close contact of the earth and oil under pressure.—C. A. M.

Glycerin analysis: Modified bichromate method for
— E. Little and B. C. Fenner. J. Amer. Leather Chem. Assoc., 1917, 12, 254—257.

A MODIFICATION of the bichromate method for rapid work is described. Five solutions are necessary: (1) basic lead acetate, made by dissolving 236 grms. of lead acetate in 1 litre of water, heating to boiling, adding 165 grms. of litharge whilst stirring, and continuing to boil for 15 mins., subsequently filtering and making up to 1 litre; (2) a cold, saturated solution of silver acetate; (3) 15% sulphuric acid; (4) $N/5$ or $N/10$ sodium thiosulphate solution; and (5) 10% potassium iodide solution. A sample containing 0.1—1.0 gm. of glycerin is washed into a beaker with 100 c.c. of water. Basic lead acetate solution is added slowly and in small quantities whilst stirring, until precipitation is complete. The precipitate should be allowed to settle after each addition. After filtering into a 250 c.c. flask, 12 c.c. of silver acetate solution is added to remove chlorides, and then sulphuric acid to remove lead and silver. The solution is made up to $\frac{1}{16}$ in. above the mark, and filtered (after shaking) into a glass stoppered flask. From the approximate strength of the original sample, the amount of bichromate is calculated which is necessary to oxidise the glycerin in 25 c.c. of the prepared solution. A quantity of bichromate 0.2—0.3 gm. in excess of this amount is weighed into a 1000 c.c. conical flask, and 25 c.c. each of glycerin solution, water, and concentrated sulphuric acid successively added, the last whilst gently shaking. If the solution turns blue more bichromate is needed and a fresh start should be made. The contents of the flask are heated for

30 mins. on the steam bath, cooled, diluted to 500 c.c., and immediately titrated with thio-sulphate solution, after adding 25 c.c. of hydrochloric acid (1:1) and 10 c.c. of potassium iodide solution. Starch paste is used as indicator. 1 gm. of bichromate used in the oxidation is equivalent to 0.1341 gm. of glycerol. The results are in excellent agreement with those obtained by the standard bichromate method.—F. C. T.

PATENTS.

Glycerin; Production of— G. J. Lemmens, Wateringbury, and P. J. Fryer, Tonbridge, Kent. Eng. Pat. 106,598, Feb. 21, 1917. (Appl. No. 2527 of 1917.)

OILS or fats are heated in an autoclave under pressure in the presence of water and zinc oxide or zinc hydroxide, and the glycerin is recovered from the liquor in the usual way. The mixture of fatty acids and zinc soaps is treated with boiling dilute sulphuric acid, the solution of zinc sulphate is separated, the zinc precipitated as hydroxide by the addition of sodium or potassium hydroxide or ammonia, and the zinc hydroxide used in the treatment of a further quantity of oil or fat.
—W. P. S.

Oils, fats, and greases; Apparatus for the extraction of— and of gelatin. H. Engel, London. Eng. Pat. 106,895, July 17, 1916. (Appl. No. 10,018 of 1916.)

THE material is extracted in one compartment of the apparatus by means of a solvent, which, with the extracted oil, etc., then passes into another chamber, where it is evaporated by means of heating coils or the like. A condenser is connected with this chamber and the solvent condensed therein is returned to the extraction chamber. Means are provided for hermetically separating the two chambers, and valves for controlling the communication of each with the condenser.—C. A. M.

Oils and fats; Preparing— for hydrogenation.
C. Dreymann, Baltimore, Md. U.S. Pat. 1,228,888, June 5, 1917. Date of appl., Dec. 6, 1915.

THE free fatty acids in the oil are converted into neutral esters by heating the oil with alcohol, a catalyst, and a dehydrating agent; the esters are left in the oil, and any remaining free fatty acids are neutralised. The glycerin may be separated from the fatty acids prior to their conversion into neutral esters.—C. A. M.

Soap and the like, and the manufacture thereof. W. Feldenheimer, London. Eng. Pat. 107,036, May 19, 1916. (Appl. No. 7194 of 1916.)

A "WATER-SOLUBLE" soap, of the character in which the lyes would ordinarily be salted out, is prepared by boiling the soap, retaining the lyes in the soap, adding china-clay or ball-clay when the soap is neutral or slightly alkaline, and running the whole direct into the crutcher and thence straight to the soap-frames, without any separation of the lyes. The clay is preferably freed from grit by the process described in Eng. Pat. 106,890 of 1916 (see page 879).—E. W. L.

Emulsifiable liquid or solid solution and method of making it. R. Vidal, Paris. U.S. Pat. 1,229,681, June 12, 1917. Date of appl., July 3, 1912.

SEE Fr. Pat. 445,053 of 1911; this J., 1912, 1190.

Paraffin, wax, fats and resins, naphtha and mineral oils; Process for obtaining from— products dissoluble in water or forming with it colloidal solutions. G. Petroff, Petrograd. U.S. Pat. 1,230,599, June 19, 1917. Date of appl., July 31, 1915.

SEE Fr. Pat. 452,054 of 1912; this J., 1913, 665.

Candle stock. U.S. Pat. 1,229,132. See IIa.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Sandarac; Detection of — in resins, lacrs, and partially manufactured materials. J. F. Sacher. *Farben-Zeit.*, 1916, 22, 188—189. *Z. angew. Chem.*, 1917, 30, Ref., 117.

THE dried material is extracted with ether, and the solution is filtered, concentrated, treated with ethereal sulphuric acid until reddish brown in colour, and finally diluted with half its volume of water. A characteristic smell is then produced which forms a very delicate test for sandarac from *Callitris quadrivalvis*. The test is not reliable for sandarac from *Callitris verrucosa* which contains pinene.—W. H. P.

Colloidal ferric ferricyanides. Haller. See VII.

PATENTS.

Paint composition. W. E. Wright, Cleveland, Ohio. U.S. Pat. 1,226,934, May 22, 1917. Date of appl., Aug. 26, 1916.

A FLAT-FINISH paint composition composed of a lead pigment together with not more than one-tenth of its weight of a mixture of about 3 parts of linseed oil, 2 parts of a semi-drying vegetable oil, and one part of tung oil.—J. N. P.

Paint for metallic surfaces subject to high temperatures. G. E. Rieck, Bremerton, Wash. U.S. Pat. 1,227,071, May 22, 1917. Date of appl., Apr. 7, 1915.

THE paint is composed of the products resulting from the reaction of japan, powdered aluminium, and "clabber" resulting from soured milk.—J. N. P.

Paint composition. O. H. Shultz, Windsor, Ontario. Assignor to F. M. Bill and R. M. Foster, Edmonton, Alberta, and L. R. Benson, Windsor, Ontario. U.S. Pat. 1,229,337, June 12, 1917. Date of appl., Mar. 14, 1916.

A PAINT composition contains the reaction products of litharge, 8; sodium silicate, 16; methylated spirit, 40; common salt, 8; alum, 8; lead acetate, 16; zinc sulphate, 32; potassium acetate, $1\frac{1}{2}$; gum arabic, 8; common rosin, 24; oxalic acid, 4; caustic soda, 32; and water, 6400 oz.—E. W. L.

Pigments; Process for obtaining —, especially black pigments, from lignite. C. Grossheim, Coln-Nippes. Ger. Pat. 297,411, Dec. 10, 1915.

COMPRESSED or briquetted lignite is raised to a white heat, complete combustion being avoided, and then quenched in water. The residue, powdered and suitably prepared, is a deep black pigment of great covering power and intensity, suitable for use as an oil or water colour. Paints prepared with it dry rapidly.—W. H. P.

Lampblack; Production of — from hydrocarbons. B. Thieme, Berlin. Ger. Pat. 297,266, Nov. 21, 1914.

GASEOUS hydrocarbon (usually acetylene) and a high-boiling liquid hydrocarbon (from coal tar or petroleum) are subjected in the same metal vessel to the action of an electric arc with a voltage of less than 1000. The arc is started without altering the position of the carbons, by means of an igniting current of higher tension from an induction coil. The lampblack remains in the liquid and sinks to the bottom, while the gaseous decomposition products (mainly methane and ethylene) mix with the acetylene in the gaseous phase. Air is now added, thus causing decomposition of the acetylene, and at the same time some of the hydrocarbons in the gaseous phase decompose further into carbon and hydrogen.—W. H. P.

Ink, and process for producing same. R. Hochstetter, Assignor to Ault and Wiborg Co., Cincinnati, Ohio. U.S. Pat. 1,226,884, May 22, 1917. Date of appl., Nov. 11, 1911.

A PIGMENT, sulphonated oil, and glycerin are thoroughly ground and mixed with about 5% of a gum varnish to form an ink, for mimeographs and the like.—J. N. P.

Varnish-bases; Process of making —. C. Ellis and L. Rabinovitz, Montclair, N.J., Assignors to Ellis-Poster Co., New Jersey, and to Indestructible Paint Co., Ltd., London. U.S. Pat. 1,226,760, May 22, 1917. Date of appl., Dec. 29, 1914.

ROSIN is dehydrated by heating and treatment with carbon dioxide, and the resulting rosin anhydride is treated at atmospheric pressure with an organic hydroxy compound, such as glycerin, to obtain a rosin ester.—J. N. P.

Varnish-removing composition. C. Ellis, Montclair, N.J., Assignor to Chadeloid Chemical Co., New York. U.S. Pat. 1,229,217, June 12, 1917. Date of appl., Mar. 21, 1917.

A PAINT and varnish remover comprises a mixture of coal-tar hydrocarbon solvents (mainly solvent naphtha), having a relatively low solvent action (less than that of benzol) on waxy material; a wax precipitant such as denatured alcohol; a wax such as paraffin wax, the purpose of which is to retard evaporation; and a relatively small quantity of carbon bisulphide, adjusted so as to ensure with the wax good film-formation.—E. W. L.

Moulding material, and process of making the same. J. P. A. McCoy, Wilkesburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,227,465, May 22, 1917. Date of appl., July 3, 1914.

SHELLAC is precipitated in admixture with sodium or potassium tannate.—J. N. P.

Composition of matter [artificial resin]. B. B. Goldsmith, New York. U.S. Pat. 1,228,428, June 5, 1917. Date of appl., Aug. 4, 1915. (See also U.S. Pat. 1,168,626; this J., 1916, 317.)

A COMPOUND soluble in acetone and having the physical characters of a resin is obtained by heating together a phenol or a fusible phenol resin and a definite compound of formaldehyde and an amine (e.g., anhydroformaldehyde-aniline). The product of the interaction is readily fusible at first, and is transformed by heat into a hard, homogeneous substance without forming any readily volatile by-product.—C. A. M.

Resin; Artificial— and process of making the same. B. B. Goldsmith, New York, Assignor to Redmanol Chemical Products Co., Chicago, Ill. U.S. Pat. 1,230,829, June 19, 1917. Date of appl., July 27, 1910.

SEE Eng. Pat. 6363 of 1912; this J., 1913, 436. The reacting substances are mixed in such proportions as to furnish at least one phenolic group of the aromatic hydroxy compound to each methylene group of the hexamethylenetetramine.

Carbonate of lead [white lead]; Process for the production of —. G. Bevilacqua, Genoa, Italy. U.S. Pat. 1,231,476, June 26, 1917. Date of appl., Feb. 16, 1915.

SEE Eng. Pat. 9201 of 1915; this J., 1916, 932.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Hevea rubber of the Amazon district, Brazil; Comparative studies on different varieties of —. F. Heim. *Bull. de l'Office Colonial*, Melun, 1916, 9, 511—516. *Bull. Agric. Intell.*, 1917, 8, 600—601.

FROM the results obtained on chemical and

physical examination of 6 samples of "Borracha fina" from different parts of the Amazon district—Fina das Ihas, F. de Caviana, F. de Amapu, F. de Cajarv, F. de Xingu, F. de Tapajoz—the author concludes that the differential properties of the *Hevea* rubber trees indigenous to the various Brazilian districts are not sufficiently marked to justify preference for seed from one particular district in the formation of new plantations. The samples studied had the characteristics of a fine medium soft Para.—E. W. L.

PATENTS.

Rubber compound. E. von Vargyas, Washington, D.C., U.S.A. Eng. Pat. 107,107, Aug. 5, 1916. (Appl. No. 11,086 of 1916.)

A RUBBER compound having a high degree of wearing quality, and suitable for pneumatic tyre outer covers, is obtained by incorporating dry cork flour, 13 to 37, and granulated iron slag, 122½ to 215, with rubber, 120 parts, and vulcanising in the ordinary way.—E. W. L.

Insulating material resembling vulcanite; Electric —. T. S. Chivers and C. Marter, Stoke Newington. Eng. Pat. 107,122, Sept. 7, 1916. (Appl. No. 12,685 of 1916.)

SPENT tan, 5 oz., is finely ground and mixed with coal ash, 1½; soot, 2½; dry black pigment, 2; and sulphur, 3 oz., and the whole is then incorporated with rubber, 2 oz., in solution. The solvent is evaporated in a current of air, and the resultant mass vulcanised in the ordinary way.—E. W. L.

Indiarubber and rubber substitutes [from paper yarn]; Manufacture of heat-resistant goods from —. H. Kramer, Dresden. Ger. Pat. 297,328, Feb. 29, 1916.

FABRICS of paper pulp yarn are formed into packing rings, hose pipes, etc., and coated first with a layer of lacquer composition and then with a solution of rubber or rubber substitute. A suitable composition is made from pitch dissolved in benzene, or other similar material, which adheres well to paper yarn and combines with the rubber solution.—J. F. B.

Caoutchouc or rubber and the like; Non-skid composition of —. C. Pacchetti, Milan, Italy. U.S. Pat. 1,230,597, June 19, 1917. Date of appl., Nov. 14, 1916.

SEE Eng. Pat. 105,026 of 1916; this J., 1917, 558.

Process of impregnating fabrics with rubber. U.S. Pat. 1,228,458. See V.

XV.—LEATHER; BONE; HORN; GLUE.

Tannery wastes; Disinfection of —. D. D. Jackson and A. M. Buswell. J. Amer. Leather Chem. Assoc., 1917, 12, 229–253.

AN account of anthrax and the means by which it is spread is followed by an account of previous work on the disinfection of tannery effluents, particularly with regard to the killing of anthrax spores. The work of the authors was undertaken in consequence of an epidemic of anthrax. Experiments showed chlorine to be the most effective disinfectant: 3 parts per 1,000,000 reduced the count of a water suspension of anthrax spores from 700 per c.c. to 0 in 45 mins. 300 parts of chlorine per million had no effect on spores suspended in a peptone solution, owing no doubt to combination of chlorine and protein. Tests were carried out on the entire effluent from a tannery during 14 months. 50 parts of chlorine per 1,000,000 was used, and only coarse suspended matter was

removed from the effluent. Anthrax, though found six times in the raw sewage, has never been found after treatment, and no further outbreaks have occurred among the cattle of the district.—F. C. T.

Tannase of Aspergillus oryzae. Kita. See XVIII.

PATENTS.

Chromium oxide; Preparing compounds of — [for tanning]. E. Voetter, Krefeld, Germany. U.S. Pat. 1,228,622, June 5, 1917. Date of appl., July 2, 1914.

ORGANIC chromium compounds are prepared by reducing chromic acid or its salts in absence of free acid other than chromic acid, with glucose, either alone or mixed with thiosulphate. The compounds are specially adapted for tanning purposes.—J. H. J.

Leather; Process of treating — for gloves. A. Aaron and G. M. Jones, Gloversville, N.Y. Assignors to L. Meyers and Son, New York. U.S. Pat. 1,230,358, June 19, 1917. Date of appl., Aug. 30, 1916.

THE grain, and the surface on the flesh side of tanned, dry leather, are removed by an abrasive wheel or other means, after which the leather is coloured.—F. C. T.

Leather; Process for the manufacture of —. O. Carr, New York. U.S. Pat. 1,230,667, June 19, 1917. Date of appl., Nov. 6, 1915.

HIDES are treated with heated circulating tanning liquor, under reduced pressure, in a specially constructed chamber. The leather fabric so produced may be acidified or waterproofed while still wet and hot. Alkaline liquors may be used for tanning.—F. C. T.

Tanning hides; Process for —. Ges. f. Chem. Ind. in Basel. Ger. Pats. (A) 297,187 and (B) 297,188, Apr. 21, 1915.

(A) HIDES or skins are tanned with soluble aromatic compounds containing two or more sulphamino groups together with a sulphonic group, but no hydroxyl or free amino groups. The lined and bated skins are immersed or shaken in a 2–5% faintly acid solution of one of these compounds, and are tanned in one or more days according to their thickness. The leather is not coloured, and is very similar to vegetable-tanned leather. (B) Hides or skins are tanned with acidified solutions of arylsulphaminobenzyldisulphonic acids.—F. C. T.

Leather substitute; Preparation of — from tanned films of bacteria or proteins. H. Siebold, Berlin-Wilmersdorf. Ger. Pat. 297,189, Apr. 7, 1914.

BACTERIAL cultures or protein substances are incorporated before tannage with leather powder (not more than 60% of the total matter), or with treated oils e.g., factis or latices of tropical plants. Too much leather powder gives a brittle product, whilst when properly prepared, the substitute is pliable and resistant to mechanical action.—F. C. T.

Adhesive; Process for obtaining a neutral, non-drying — [from waste products of breweries]. H. Kühle, Darmstadt. Ger. Pat. 297,186, Sept. 15, 1915.

AN improvement on Ger. Pat. 264,291 (this J., 1913, 1079). During or after concentration of the brewery waste, molasses is added. The alkaline salts of the molasses react with the acid substances of the yeast, etc., and a neutral non-drying adhesive is obtained.—W. H. P.

Tanning and impregnating materials by means of electricity; Process for —. B. Schwerin. Frankfurt, Assignor to Elektro-Osmose A.-G. (Graf Schwerin Ges.). Berlin, Germany. U.S. Pat. 1,229,150, June 5, 1917. Date of appl. Sept. 8, 1914.

SEE Eng. Pat. 19,819 of 1914; this J., 1915, 1020.

Tanning fish-skins or the like; Process for —. K. Bendixen. Assignor to Skindfabriken Unicum, K. Bendixen. P. Bendixen & Co., Copenhagen, U.S. Pat. 1,230,266, June 19, 1917. Date of appl. Feb. 19, 1912.

Apparatus for the extraction of oils, fats, and greases and of gelatine. Eng. Pat. 106,895. See X11.

XVI.—SOILS; FERTILISERS.

Muscovite; Action of solutions of ammonium sulphate on —. R. F. Gardiner and E. C. Shorey. J. Ind. Eng. Chem., 1917, 9, 589—590.

MUSCOVITE is of common occurrence in soils, and is usually regarded as one of the most stable of soil constituents. The finely ground mineral (0.15 to 0.6 gm.) was treated with 10 c.c. of solutions of ammonium sulphate of from 0.5 to 1.5% strength for 24 hours at temperatures of 20° to 80° C. The amount of potassium oxide extracted ranged from 1.65 to 3.73% (25.5 to 57.65% of the total amount present). Increase in the concentration of the salt solution caused but slight differences in the proportion of potassium oxide extracted, nor was the influence of temperature very pronounced, although the extraction was greater at temperatures above 20° C. In parallel experiments in which the muscovite was heated for 1 hour in an autoclave at 160° C. with water only, and with a 4% solution of ammonium sulphate, the amounts of potassium oxide made soluble were 4.32%, and 47.3% of the total quantity respectively. Orthoclase treated with 1.5% ammonium sulphate solution at 65° C. yielded 0.08 to 0.25% of soluble potassium oxide, corresponding to 1.03 to 3.23% of the total quantity present.—C. A. M.

Soil; Influence of crop, season, and water on the bacterial activities of —. J. E. Greaves, R. Stewart, and C. T. Hirst. J. Agric. Res., 1917, 9, 293—311.

SAMPLES of soil were taken in foot sections from each plot of the experimental field and were analysed. The field was divided into five sets of plots, the first of which was left fallow, whilst the others were planted with alfalfa (lucerne), corn (maize), potatoes, and oats. A maximum, medium, and minimum application of water was made to three of each of the sets respectively whilst one was left unwatered. Samples of the soil were taken in April, July, and October–November and were analysed and examined bacteriologically. It was found that the amount of nitric nitrogen in the top 6 ft. of alfalfa soil was relatively low throughout the period, but was higher in autumn than in spring or summer. The amount rose with the increase in the water applied, but reached its maximum per acre-inch of water when only 15 in. of water was applied. In the case of the plots containing potatoes, oats, and maize, and also of the fallow ground, the amount of nitric nitrogen in the surface 6 ft. of soil decreased with increase of water, but the quantity formed in the soils containing the crops was greatest when most water was applied. The maximum per acre-inch of water was reached when only 15 in. of water was applied. The disappearance of large quantities of nitric nitrogen from the fallow soil during the summer months was attributed to the bacterial conversion of this nitrogen into proteins, and not

to denitrification. Larger applications of water (37 and 25 in.) conveyed much of the nitric nitrogen beyond the reach of the plant, and this explains the decreased yields of crops frequently observed on soils which have been excessively irrigated. The application of water to the soil reduced the number of micro-organisms capable of growing upon an agar medium, in the case of soils containing alfalfa, oats, and potatoes, but increased them in the fallow soil. The results obtained with the maize soil were irregular. The application of water to the soils increased the capacity for producing ammonia, except in the case of alfalfa soil, and the nitrifying power, except in the case of the oat soil. The temperature to a depth of 4 ft. was 2° F. higher in the unwatered than in the watered soils. The number of micro-organisms was higher in the soils on which crops were grown than in the fallow soil, this being probably due to plant residues left in the soil in the case of the former. The ammonia-producing capacities of the soils were in the following ascending order:—Alfalfa, oats, maize, potato, and fallow soils. Arranging them in increasing nitrifying powers they were:—Fallow, maize, oats, alfalfa, and potato soils. Alfalfa not only consumed more nitric nitrogen from the soil than the other crops, but also increased the nitrifying power of the soil. Hence it would deplete the soil of nitrogen more rapidly than the other crops, if the whole of the crop were removed. Irrigation increases the bacterial activity of the soil, and thus renders the nitrogen soluble, but if excessive quantities of water are used much of this nitrogen is washed from the soil, which then gives a reduced yield.—C. A. M.

Soil; Effect of decomposing organic matter on the solubility of certain inorganic constituents of —. C. A. Jensen. J. Agric. Res., 1917, 9, 253—298.

IX experiments to determine the extent to which the beneficial action of decomposing organic mulches is due to solution of mineral constituents in the soil, aqueous extracts were made of alfalfa (lucerne) hay, sweet clover, and barley hay. In each case 70 grms. of the finely chopped material was saturated with distilled water in a bottle and allowed to ferment for 14 days, and then thoroughly shaken with 1500 c.c. of water, and the extract filtered first through muslin and then through a Chamberland filter. The insoluble matter was again treated in the same way, and further extracts obtained. These extracts were added to the soils in the proportion of 250 grms. of soil to 500 c.c. of extract. Two types of soil, a clay loam and a sandy loam, were used. It was found that these aqueous extracts removed from the soil from two to five times as much calcium as was added to the soil with the extract. As a rule they also removed more magnesium than they introduced, the increase ranging from a trace to about 80%, but the amount of iron and phosphoric acid removed was less than that added to the soil by the extracts. At the same time, the amount of iron dissolved from the soil was from 1.7 to 5.4 times the amount dissolved by water. The solvent action of the various preparations, whether derived from leguminous or non-leguminous plants, was closely similar. Extracts prepared in the same way from cow manure removed less calcium from the soil than the vegetable extracts, but had much the same solvent action upon the other mineral constituents. Both the inorganic and organic salts in the aqueous extracts appeared to play a part in dissolving the mineral substances in the soil. Green manures kept moist until thoroughly decomposed yielded extracts which dissolved much more calcium from the soil than they introduced, and also removed considerably more magnesium, phosphoric acid, and iron than was dissolved by water alone. These aqueous extracts were not alkaline to phenolphthalein, nor acid to methyl orange. By mixing soil

with 3% of green manure and stable manure and allowing partial decomposition to take place, the solubility of the calcium and phosphoric acid in the soil was increased by 30 to 100%. The effect of the organic constituents of the extracts was shown by experiments in which green manures and sugar were hydrolysed with strong acid, and then washed free from acid, and extracted with ammonia. These extracts when freed from ammonia represented artificial humus solutions free from calcium, magnesium, iron, and phosphoric acid. When added to the soil they increased the solubility of the calcium by amounts ranging from a few parts to 240 parts per million of soil, as compared with the solubility in water. They also caused a slight increase in the solubility of magnesium, phosphoric acid, and iron.—C. A. M.

Peat soils, waste and cultivated: Micro-organisms of —. T. Arnd. Centr. Bakt., 1916, 45, 554—574. Bull. Agr. Intell., 1916, 7, 1744—1745.

PRELIMINARY trials at the Bremen Experiment Station to ascertain the effect of drainage, liming, and tillage on the bacterial life of peat soils, gave the following general results. Ammonifying organisms were present in all samples, but were far more active in surface soils than in subsoils, and in cultivated than waste land. The breaking up of waste land only affected the bacterial life to a depth of about 8 ins. of soil. No nitrifying organisms were found in waste land or cultivated land, except such as received a dressing of more than $\frac{1}{2}$ ton of lime per acre; more than 1 ton per acre would appear to be necessary to produce active development of the nitrifying organisms in the peat itself. All the samples tested were able to reduce nitrates; the surface soil of waste land was not much more active than the subsoil, but the surface soil of cultivated land showed much more activity, especially where tillage had been accompanied by liming. Similar relations were observed in respect of the power of decomposing cellulose. As with ammonification and nitrification, the maximum decomposition of cellulose occurred when the soil had previously received a dressing of dung. In no sample of soil was *Azotobacter* present. Surface soils and cultivated soils fermented mannitol more readily than subsoils and waste land, the maximum effect again being obtained with a dunged plot.—J. H. L.

Plant food in the leaves of forest trees. P. Serex-jun. J. Amer. Chem. Soc., 1917, 39, 1286—1296.

ANALYSES of maple, chestnut, and oak leaves showed that the quantities of phosphoric acid, nitrogen, and potash contained in the leaves varied with the species of tree, the portion of the tree from which the leaves were obtained, and the kind of soil on which the trees were growing. Briefly, the autumn leaves contained from 1.3 to 3.0% of nitrogen, 0.5 to 1.4% of P_2O_5 , and 0.7 to 1.4% of ζ_2O (all calculated on the dry substance); slightly higher amount of these constituents were present in the leaves during the early summer months. The cost of collecting and handling the leaves would probably be greater than their manurial value.
—W. P. S.

Mineral phosphates and superphosphates: Solubility of — in dilute mineral and organic acids. A. Aita. Annali Chim. Appl., 1917, 9, 200—210. (See this J., 1916, 974, 1074.)

Each determination 2.5 grms. of the phosphate was digested for 30 mins. at 14° to 15° C., with 50 c.c. of the dilute sulphuric, hydrochloric, formic, acetic, oxalic, tartaric, or citric acid solution, the mixture being frequently stirred. The mineral acids were used in strengths of $\frac{1}{16}$ to $\frac{1}{10}$ gm.-equivalent per litre and the

organic acids in $\frac{1}{2}$ or 1 gm.-equivalent per litre. It was found that in the case of the inorganic acids the solubility of the phosphoric anhydride in superphosphate was comparable with that obtained with the mineral phosphates, after making allowances for such factors as fineness, friability, and proportion of lime. In the case of the organic acids, mineral phosphates behaved in the same way as when treated with inorganic acids, except that there was a slighter dissociation, and that the influence of other constituents was more pronounced. Superphosphates, however, behaved in the same way as mineral phosphates towards oxalic acid, but yielded a high proportion of phosphoric anhydride to the other solutions. For example, the following amounts of the total phosphoric anhydride were extracted:—With formic acid, 73.28; acetic acid, 62.61; oxalic acid, 24.44; tartaric acid, 66.43; and citric acid, 77.87%. The formation of complex citrophosphates in combination with aluminium and ferric iron has been shown (this J., 1916, 1074) to be the cause of the high citric solubility of phosphoric acid, and it would seem that similar complex compounds are formed with organic acids containing atoms of hydrogen not in combination in carboxyl or hydroxyl groups. The solubility of the phosphoric anhydride in superphosphates is somewhat less than that of mineral phosphates in dilute mineral acids, but the solubility of the phosphoric anhydride is almost equal in both cases in organic acids which have the property of forming compounds with phosphoric acid, aluminium, and ferric iron.

—C. A. M.

"Tetraphosphate": Fertiliser trials with — in Piedmont rice fields, Italy. Marcarelli and Novelli. Giorn. Riscoltura, 1916, 6, 321—327. Bull. Agric. Intell., 1917, 8, 230—231.

EXPERIMENTS were made in an extremely acid soil, very poor in lime, growing rice. The field was in a fertile condition at the commencement of the experiments, having received a dressing of mineral superphosphate and farmyard manure during the previous winter. Three equal areas of the field were sown with paddy rice and manured with 500 kilos. per hectare of tetraphosphate, the same amount of ground phosphorite, and 930 kilos. of superphosphate. The amount of marketable grain obtained from the tetraphosphate plot was 6330 kilos., from the ground phosphorite plot 5730—5906 kilos., and from the superphosphate plot 5690 kilos. The tetraphosphate contained 2% of citrate-soluble, 7.8% of citric acid soluble, and 28.3% total P_2O_5 .—J. H. J.

Phosphoric acid in mixed fertilisers containing superphosphates: Factors influencing the solubility of —. E. V. Flack. S. African J. Sci., Dec., 1916.

No appreciable loss of soluble phosphoric acid takes place within three weeks when superphosphate is mixed with potassium sulphate or kainit, and an actual increase may occur when the fertiliser is mixed with ammonium sulphate. Admixture of superphosphate with guano results in a decrease of the soluble phosphoric acid to the extent of 7% within 3 hours, whilst in a mixture of superphosphate and bone-meal the loss of soluble phosphoric acid may amount to 14.5% in fourteen days.
—W. P. S.

Cane molasses [and vinasses]: Utilisation of the fertiliser constituents contained in —. W. E. Cross and W. G. Harris. Rev. Ind. y Agric. de Tucuman, 1916, 7, 95—103. Intern. Sugar J., 1917, 19, 281—283.

THE ash obtained by the incineration of Tucuman cane molasses is particularly rich in potash, nitrogen, and phosphoric acid, the amount of the former constituent being 45—50% as K_2O , corres-

ponding to 66–73% K_2CO_3 . Hence this material might well at the present time be sold as such as a fertiliser, or it might be further purified by fractional crystallisation. Vinasses especially would repay utilisation in this way, and the authors have observed that after acidifying the partially evaporated product with sulphuric acid, it can be evaporated completely to dryness, yielding a black dry powder suitable for transport in bags or barrels, whereas by concentration in the ordinary way a pasty hygroscopic substance results. Deerr and Peck have proposed to separate the nitrogenous bodies from cane molasses by heating with lime, utilising the precipitate separated in a filter-press as a fertiliser; but the authors have found in the case of Tucuman molasses that only a small proportion of the nitrogen can be eliminated by this process.—J. P. O.

Metabolism of nitrogenous substances in plants; rôle of ammonia in the —. D. N. Prianchnikov. Collected Papers of Agronom. Inst. of Moscow, 1916, 10, 1–24. Bull. Agric. Intell., 1917, 8, 204–211.

IN the life of the higher plants, ammonia plays an important part as the starting point for the synthesis of protein and as an end product in the oxidation of nitrogenous substances. It does not however accumulate as such, but is converted into asparagine. Plants may be divided into three types according to the facility with which they accomplish this synthesis of asparagine: (a) Plants which readily absorb ammonia from solution and convert it into asparagine. *Hordeum sativum* (barley), *Zea mays* (maize), and *Cucurbita pepo* (pumpkin) belong to this group. (b) Plants in which the absorption of ammonia is very feeble and in which the presence of ammonia in the culture solution retards the oxidation of nitrogenous substances. The absorption of ammonia can be increased by adding calcium carbonate to the culture solution. *Pisum sativum* (pea) and *Vicia sativa* (vetch) are plants of this type. (c) Plants in which the presence of ammonia in the culture solution prevents the conversion of ammonia into asparagine. The addition of calcium carbonate has no effect in these cases. The yellow lupin (*Lupinus luteus*) is an example of this type.—J. H. J.

Calcium; Function of — in the nutrition of garden pea seedlings with ammonium salts. V. A. Morosov. Papers from Laboratory of Prof. Prianchnikov, Moscow Institute of Agriculture, 1916, 10, 391–395. Bull. Agric. Intell., 1917, 8, 214–216.

IN the assimilation of ammonium salts by plants the base is absorbed and the acid left; this acid requires to be neutralised if continued assimilation is to go on. Experiments were made with sprouted seeds of the garden pea grown in solutions of ammonium sulphate alone, ammonium sulphate and calcium carbonate, and ammonium sulphate and ferric hydroxide. The best development of the seedlings occurred with the solution containing calcium carbonate, the second best with ferric hydroxide, whilst that with ammonium sulphate alone was poorer than with distilled water. The greatest accumulation of total nitrogen and asparagine nitrogen in the seedling also occurred with calcium carbonate followed by ferric hydroxide, whilst the ammoniacal nitrogen was least with calcium carbonate. Thus calcium carbonate does not act merely as a neutralising agent, but the calcium present also exerts its own specific nutritive influence.—J. H. J.

Plants; Biochemistry of —. A. Stutzer. Biochem. Zeits., 1917, 80, 163–151.

IT has been shown that the heart-rot and dry-rot

diseases of sugar beet and certain parasitic diseases of oats are in all probability due to the presence of alkaline substances in the soil in which they are grown. A garden soil which affected *Syringa vulgaris* (filix) was found to contain 0.88 gm. of water-soluble alkali per kilo. of dry soil. Roses grown in the same soil were greatly damaged by blight, although other plants (*Lathyrus odoratus*, *Roseda*, *Traprobium*, etc.) grew well. The affected roses recovered completely when peat dressing containing 16.6 grms. of acid (as H_2SO_4) per kilo. of air-dry material was applied. In a vineyard in which *Oidium* and *Peronospora* were very troublesome, the dried soil was found to contain 0.5 gm. of soluble alkali per kilo. On the other hand, the field thistle (*Cirsium arvense*) grew abundantly and vigorously in a soil containing 0.98 gm. of soluble alkali per kilo., and it is known that some plants grow best in acid soils. Investigations on the effect of the reaction of the soil on the growth of different species of plants and on plant parasites are urgently needed. The method used by the author for determining acid or alkaline substances in soils (see this J., 1915, 1064) consists in treating an aqueous extract of the soil with a solution of potassium iodide and iodate and titrating the liberated iodine with thiosulphate. If the extract is alkaline it is first treated with a known excess of standardised sulphuric acid; 1 c.c. of N/100 thiosulphate represents 0.00049 gm. of alkali, i.e., the mean of the equivalents of sodium and potassium hydroxides.

XVII.—SUGARS ; STARCHES ; GUMS.

Sugar cane ; After-ripening of — *Chemical changes taking place after cutting.* J. H. Barnes. Agric. J. India, 1917, 12, 200—215.

IN the Gurdaspur District, India, the stripped cane is allowed to remain in heaps for a day or so before crushing, it being thought by the peasant farmers that the *gur* obtained is lighter in colour and drier than that resulting from cane crushed immediately. Results obtained from numerous experiments with Katha or Chin and other local varieties showed that storing the cane in this way tends to further ripening with increase of the sucrose content ; but that, on the other hand, there is a danger of loss of sugar by inversion and decomposition if more than a certain time, depending upon the temperature of the air and the condition of the cane, be exceeded. The system used in Java of covering cut cane with damp "trash" in the event of the breakdown of the milling plant, is applicable only so long as the cell protoplasm is alive and the ordinary chemical processes of the cell can continue. When the cane is dead, chemical reactions of hydrolysis and oxidation by enzymes get beyond control, and the rate of sugar decomposition becomes very high.—J. P. O.

Masseccutes and after-products ; "Frothy fermentation" of second jet — in beet sugar factories. R. Gillet. Intern. Sugar J., 1917, 19, 264—269.

EXPERIMENTS are described tending to prove that the "frothy fermentation" of beet masseccutes and after-products may be caused by the agency of a thermophilic micro-organism, having its optimum temperature at about 70° C., which produces evolution of carbon dioxide. It may be cultivated in a medium containing invert sugar, neutral or slightly acid to phenolphthalein, but its growth is inhibited by alkalinity, especially at higher temperatures. Referring to the chemical theory advanced by Lafar, that the phenomenon is due to the combination of invert sugar with the amino-acids of the organic non-sugar present, causing a considerable evolution of carbon dioxide, the author states that he has observed a case of frothy fermentation in a beet after-product containing nitrogen in quantity much too small to cause appreciable evolution of carbon dioxide by such a reaction.—J. P. O.

Aldoses ; Determination of — J. Bougault. Comptes rend., 1917, 164, 1008—1011.

ALDOSES can be estimated by measuring the quantity of iodine required for their oxidation, in presence of sodium carbonate, in accordance with the equation :—

The reaction is not instantaneous but takes place with a velocity depending on the excess of iodine present and on the alkalinity, and is retarded by the presence of bicarbonate. A secondary reaction also takes place but much more slowly. The estimation of the aldoses (dextrose, mannose, galactose, arabinose, lactose, and maltose) is effected by adding an excess of iodine, and titrating samples of the solution at regular measured intervals until the loss of iodine reaches a low constant value which occurs within half an hour (90 mins. in the case of mannose) and indicates

completion of the chief reaction. The correction for the reduction of iodine, due to the secondary reaction, can then be estimated and applied. Ketoses and sucrose are oxidised by the iodine very slowly, so that their presence is usually without appreciable influence on the determination of the aldoses. In the absence of other oxidisable organic compounds, the quantity of aldose present with sucrose in a proportion as low as one part in a thousand can be satisfactorily estimated by iodine, by comparing the reduction with that given in the same time by pure sucrose. The method can also be used for determining the molecular weight of an aldose, or as a criterion of its purity when the molecular weight is known. (Compare Bland and Lloyd ; this J., 1914, 948.)—J. N. P.

Arabinose ; Kinetics of furfural formation from — R. Kremann and H. Klein. Monatsb. Chem., 1917, 38, 63—75. J. Chem. Soc., 1917, 112, ii., 251—252.

THE authors have studied the kinetics of the formation of furfural from arabinose by the action of sulphuric acid and hydrochloric acid at 95° C. The results are expressed in dx/dt curves, where dx represents the amount of furfural semioxamizide formed at the time dt . The results fall on to two different curves, the one being an S-shaped curve, the other a slowly rising curve. There is no apparent reason why the results should fall on one curve rather than on the other. The author concludes that at 95° a high concentration of hydrogen ions can produce in arabinose solutions, in the course of the reaction, either a positive catalyst *A*, which accelerates the furfural formation autocatalytically, or a catalyst *B*, which accelerates the subsidiary reaction, so that in the latter case only one-third of the quantity of the furfural expected appears to be formed. With decreasing acid concentration the two curves come closer together, and eventually coincide to represent a reaction of the first order. The S-shaped curve is represented by the typical equation for an auto-catalytic reaction.

Starch ; Practical method for determining the viscosity of — for mill purposes. G. M. MacNider. J. Ind. Eng. Chem., 1917, 9, 597—599.

TO ascertain the viscosity of starch solutions after being boiled with steam for an hour, as is done in the preparation of warp sizing, etc., in the mill, a miniature kettle of about 1½ galls. capacity, similar in every respect to the large kettles used in the mill, was employed. The amount of starch to be taken varies with the grade of the starch. For thick-boiling maize, potato, and similar starches 0.5 lb. per gall. of water is used ; for medium thin-boiling starch, 1 lb. ; and for very thin maize starch and other chemically treated starches 2 to 2.5 lb. per gall. The weighed quantity of starch is added to 1 gall. of cold water in the kettle, and the agitators are run for 10 to 15 mins. until a smooth cream is obtained, when steam is admitted and the solution is boiled for 1 hour after the boiling point has been reached. Some of the solution is then rapidly transferred to the cup of a Scott viscometer, and 50 c.c. is run out into a graduated vessel. The number of seconds required to deliver 50 c.c. of the solution, divided by the number of seconds required to deliver 50 c.c. of boiling water, gives the viscosity (this J., 1912, 680). Tested in this way, various grades of thick-boiling starch (0.5 lb.) showed a viscosity of 2.89 to 4.58, whilst thin-boiling starches (1 to 2 lb.) gave a viscosity of 1.27 to 2.45. A maize starch solution (4 lb. per gall.) had a viscosity of 3.51, which was reduced to 2.63 by the addition of 2 oz. of potassium hydroxide. The effect of the addition of the chlorides of calcium, magnesium, zinc, etc., upon the thickness of the starch may be determined in the same way.—C. A. M.

Fertilisers [from molasses]. Eng. Pat. 106,858. See XVI.

XVIII.—FERMENTATION INDUSTRIES.

[*Brewing:*] *Saccharification of raw cereal mash* [in —]. G. Thevenot. Communications U.S. Master Brewers' Assoc. Brewers' J., 1917, 53, 250—253.

IN employing raw cereals as brewing adjuncts it has hitherto been the practice to cook them before use, to liquefy the starch. The author states that equally satisfactory results, as regards yield of extract and quality of worts, may be obtained without the preliminary cooking, if the adjuncts are finely ground, not necessarily to flour, but to fine meal which still feels gritty to the touch. It is only necessary to allow a longer period than usual for saccharification, and in some cases to carry out this process at temperatures above 70° C. Comparative laboratory mashings were made with 60% of malt and 40% of raw grits (maize), the latter being used in the cooked state and also after simply being passed several times through a two-roller *Rehle* mill set as close as possible. The mashings were held for 30 mins. at 15° C., and then slowly (in 25 mins.) raised to 70° C. for saccharification. In the mash containing uncooked adjunct, saccharification occupied 25 mins. as

compared with 9 mins. in the other case; the wort from the former mash was quite as satisfactory as the other as regards composition, filtration, colour, odour, flavour, and break, and the yield of extract from the uncooked grits was slightly higher than from the cooked grits. Similar trials were made with other raw adjuncts, viz., refined grits, rice, and barley. To obtain the maximum yield of extract it was found necessary, however, to raise the temperature of saccharification to 72.5°—73.7° C. for the refined grits and to 75° C. for the rice; saccharification was then complete in 45 mins. in both cases. With barley as adjunct the ordinary temperature, 70° C., was employed, and saccharification occupied only 5 mins. In all these cases yields were obtained equal to or slightly higher than those given by the same adjuncts previously cooked, and the worts produced were entirely satisfactory. Mashings with malt and uncooked raw grits were carried out on a larger scale (12-barrel brews), with similar results. In laboratory mashings of the finely ground uncooked adjuncts alone, *i.e.*, without malt, under the same conditions as for the combined mashings, the following yields of extract (referred to dry substance) were obtained:—69.18% from raw grits, 9.92% from refined grits, 8.62% from rice, and 44.85% from barley, so that, contrary to published statements, some of these raw adjuncts must contain considerable amounts of liquefying diastase.

—J. H. L.

Beers and ales: A study of American — L. M. Tolman and J. G. Riley. U.S. Dept. of Agr., Bureau of Chem., Bull. No. 493, Mar. 21, 1917. Reprinted in J. Inst. Brew., 1917, 23, 298—322.

THE course of manufacture of typical malt products was observed from beginning to end in three American breweries, and the results of analysis of the worts, before and after fermentation, and in some cases after storage, are given in a series of tables. These data relate to (1) all-malt beers, (2) beers made from malt and rice or malt and maize, (3) porters made from malt, cerealine, and sugars, and (4) ales made from malt and cerealine with or without sugars. The average value of the ratio of extract loss to alcohol produced during fermentation was practically the same, 2.12, for the bottom-fermentation products (beers) and the top-fermentation products (ales, porters, stouts). Whilst in the case of beers, however, the extract loss was practically identical with the sugar loss, in the case of top-fermentation the former value exceeded the latter by amounts ranging from 1.47 to 2.65 grms. per 100 c.c., these differences no doubt representing dextrin fermented. There was found to be no appreciable development of volatile acidity during fermentation and only a slight increase in fixed acidity, averaging 0.049% in the case of beers and 0.103% in the case of ales. The average losses of protein, ash, and phosphoric acid during fermentation, for the different classes of products, showed only small variations, viz., 0.168—0.275 grm. of protein, 0.014—0.045 grm. of ash and 0.013—0.019 grm. of phosphoric acid (P_2O_5) per 100 c.c., and there was practically no further loss during storage in the cases investigated. The results of analysis of a large number of American beers, besides those referred to above, are given in tables. The conclusion is drawn that American all-malt beverages can be distinguished from those made with the use of adjuncts, by means of their contents of protein, ash, and phosphoric acid, if for comparative purposes these values are calculated on a uniform basis of original gravity. The all-malt beers analysed contained 0.230—0.336% of ash, 0.701—1.079% of protein ($N \times 6.25$), and 0.087—0.143% of phosphoric acid, calculated to a uniform original wort gravity of 15%, whilst beers and ales made from malt and 20% or more of rice, maize, cerealine, or sugar, in

no case contained more than 0.223% of ash, 0.59% of protein, and 0.076% of phosphoric acid. The marked difference in the protein-content of the two classes of products, which is not observed with European beers, is a consequence of the relatively high nitrogen-content of American brewing barleys. Analysis of 72 samples of present-day American beers of various origin showed an average alcohol-content of 3.52% by weight, and an average original wort gravity of 12.5%; these values are respectively 1.11 and 2.23% lower than corresponding ones published 30 years ago.—J. H. L.

Beers; Iron-content of brewing materials in relation to sedimentation in bottled —. A. Fischer. Amer. Soc. Brew. Technol., Chicago Section. Feb. 21, 1917. Western Brewer, 1917, 46, 164—167.

It is well known that contact of beer with certain metals, notably tin, may give rise to turbidity and deposit, and iron has also been regarded as detrimental in this respect. In order to ascertain whether the small quantities of iron contained in brewing materials may affect injuriously the beer produced, the author determined the iron-content of brewing materials and products. Malt was found to contain 0.005—0.02% of iron (calculated as ferric oxide), rice 0.0034—0.0051%, maize products 0.00017—0.01%, and hops 0.042—0.118%, whilst beer contained only 0.00003—0.00019%. Nearly the whole of the iron contained in brewing materials remains in the spent grains and hops, only about 1% passing into the beer. The traces of iron sometimes present in sugars used as *krausen* do not pass into the beer, but either remain undissolved or are again eliminated by the yeast.—J. H. L.

Malt amylase; Modification of the amylolytic activities of — and their behaviour on keeping in presence of different reagents. T. Chrzaszcz and A. Joscht. Biochem. Zeits., 1917, 80, 211—241.

AMYLASE preparations were made from ground barley malt, using as extracting media water and a large number of other substances in the form of aqueous solutions, and the extracts (5% or 8% concentration) were tested in regard to their starch-liquefying power (modified Lintner-Solleid method; this J., 1910, 583), saccharifying power (reducing sugars determined by Bertrand's method; this J., 1907, 60), and dextrin-forming power (colour reaction with iodine solution), tests being made immediately after preparation and after keeping for different periods, up to 2½ years in some cases. The results are tabulated. They show clearly that there is no definite relation between the liquefying and saccharifying powers of the amylase, the ratio varying widely according to the experimental conditions, and it is concluded that these powers are due to separate enzymes (see this J., 1912, 1089). The results are not conclusive in regard to the dextrin-forming power, which varies mostly in accordance with the liquefying power, but sometimes with the saccharifying power. Probably the dextrin-forming power is a separate function of the amylase in causal connection with the liquefying and saccharifying powers, but it may be a resultant of the two last-named functions under conditions which have not yet been determined. An amylase preparation cannot be adequately characterised by determinations of any one of its functional activities, but only by methods in which at least three of its four functions (the starch-precipitating power has been disregarded in the present investigation) are taken into consideration. The results obtained show that the media commonly used for the preparation of amylase, viz., water, alcohols, acetone, and chloroform, are not the most suitable for the

purpose. Glycerin at concentrations of from 20 to 90%, but preferably 50%, pyridine solution (3% or 6%), and quinoline water are much more effective in preventing growth of micro-organisms and maintaining intact the amylolytic power of amylase preparations over long periods. Bases, both inorganic and organic, act favourably on the liquefying and dextrin-forming powers of amylase, but unfavourably on the saccharifying power. Alcohols, on the other hand, act more injuriously on the liquefying and dextrin-forming powers and only to a lesser extent on the saccharifying power. Ammonium sulphate, urea, and asparagine have a favourable effect on the enzymic activity of the amylase, but are not capable of preventing the growth of micro-organisms.

Diaslase; Independence of the optimum temperature of a — of the concentration of substrate and enzyme. A. Compton. Ann. Inst. Pasteur, 1916, 30, 496—502. Bull. Agr. Intell., 1916, 7, 1755.

IX experiments on the action of takadiastase on maltose solutions of concentrations ranging from M/30 to M/5, the optimum temperature of hydrolysis, 47° C., was found to be independent of the concentrations of substrate and enzyme. (Cp. this J., 1914, 977.)—J. H. L.

Tannase of Aspergillus oryzae. G. Kita. Kogyo-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 131—138.

FERNBACH and Pottévin (this J., 1901, 137) found that *Aspergillus oryzae* secreted tannase when it was grown in a medium containing tannin, and Yanagisawa has recently patented a process for utilising the tannase technically in distilleries using raw materials containing tannin. Experiments by the author showed that *Aspergillus oryzae* grows well in a medium containing tannin (e.g., 2 grms. of tannin in 250 c.c. of 7.5% starch solution), but the growth is somewhat impaired if the tannin content be unduly high, e.g., in a medium containing 20% of bran. *A. oryzae* secretes tannase even when grown in a medium free from tannin, whereas, according to Fernbach, this is not the case with *A. niger*. The tannase-activity increases with the tannin-content of the culture medium. There is a relation between the starch-saccharifying power of koji and the growth of *A. oryzae*, and hence there exists an optimum for the saccharification of tannin-containing material with bran-koji containing tannin.

Enzymes; Formation of —. II. M. Jacoby. Biochem. Zeits., 1917, 80, 357—363. (See this J., 1917, 663.)

UREASE-SECRETING bacteria were grown in a broth medium, from which sub-cultures were grown in Uchinski's solution (8 c.c. of glycerol, 1.2 grms. of sodium chloride and of ammonium lactate, 0.8 gm. of sodium asparaginate, 0.5 gm. of dipotassium phosphate, 0.08 gm. of magnesium sulphate, and 0.02 gm. of calcium chloride dissolved in 200 c.c. of water), and in the same solution with the addition of 8 c.c. of a 1% solution of ferrous sulphate. In the two last-named media growth practically ceased after the second generation, but commenced again on addition of even a small quantity of the broth medium; the same holds good in regard to the formation of urease by the bacteria.

Teslitupin; New substance. —. prepared from beer yeast. E. Moufang and A. Mayer. Allgem. Z. Bierbrau., u. Malzfabr., 1917, 45, 19. Woch. Brau., 1917, 34, 46.

THE authors, who have previously drawn attention to the decolorising and reducing properties of dead yeast (see this J., 1913, 303; 1915, 1159), claim to have extracted from beer yeast, by a

method not described, a substance, testilupin, which accelerates fermentation by living or dead yeast, and possesses strong reducing powers. It reduces Fehling's solution in the cold, potassium permanganate and phenylhydrazine, and decomposes hydrogen peroxide. It is capable of reducing aqueous solutions of "methylene blue" and does not lose its decolorising power on continued use.

—J. H. L.

Wine yeasts. E. Kaiser. Rev. Viticulture, 1916, 45, 149—155, 165—170. Bull. Agr. Intell., 1917, 8, 118—152.

THE author investigated the influence of addition of 1% (or in some cases 1.7%) of nitrogen, in the form of ammonium sulphate, asparagine, and ammonium phosphate, on the formation of esters during the fermentation of sterilised grape must by various wine yeasts from the Laboratory of the Agronomic Institute, viz., yeasts 7 (St. Emilion), 32 (Langdale, Gard), 88 (Chambertin), 94 (Musigny), 255 (pointed Burgundy yeast), 101 (*Folle blanche* Cognac yeast), and 42 (Sauterne). In most cases the added nitrogen increased the production of esters, especially non-volatile esters, but the yeasts showed marked individual differences which preclude generalisations. Ammonium sulphate had usually less effect than the other forms of nitrogen. In ammonium phosphate both the nitrogen and phosphorus were obviously effective, and powerfully stimulated yeast development and fermentation; in some cases this salt doubled or trebled the production of non-volatile esters.

—J. H. L.

Cider spirits; Composition of —. E. Kayser. Bull. Soc. Agric. France, 1916, 262—265. Bull. Agr. Intell., 1916, 7, 1838—1840. (See also this J., 1917, 608.)

APPLE must was fermented by *Saccharomyces mali Risleri* (yeast 153 of the Laboratory of the Agronomic Institute), alone and together with an apiculated ferment (yeast 158), and the distillates from the fermented liquids were analysed. Fermentation was started at 26° C. and completed, in some cases at 26° C. and in others at room temperature. The distillates differed considerably from ordinary cider spirits in composition, their ester-content being markedly lower than their content of higher alcohols and not very different from their aldehyde-content. The sum of acids, aldehydes, furfural, esters, and higher alcohols in the distillates ranged from 375 to 618 mgrms. per 100 c.c. of alcohol; the higher values were the result of fermentation at 26° C., the lower and fluctuating room temperature favouring only the formation of acids. Addition of phosphates before fermentation increased the production of all the volatile impurities at 26° C., and the production of aldehydes at room temperature to a very marked extent. The effect of the apiculated yeast varied with the temperature of fermentation, but was favourable to

Maximum cost per lb. of hexose, cents	1.0
Minimum cost per proof gall. of alcohol, cents	9.6

the formation of esters and aldehydes, and unfavourable to the formation of higher alcohols.

—J. H. L.

Alcohol; Cheap production of —. A. M. Breckler. J. Ind. Eng. Chem., 1917, 9, 612—615.

THE total quantity of alcohol produced in 1914 in U.S.A. was 182,000,000 proof galls., which was equivalent to about 5% of the total consumption of petroleum spirit. The bulk of this alcohol was derived from grain, and it is estimated that to produce sufficient alcohol to replace petroleum spirit as a motor fuel, 16% of the total cereal production or about 26% of the maize production (U.S.A.) would be necessary. The average price,

during the past 5 years, of alcohol from maize has been 17.5 cents per proof gall., and this year the cost will be about 25 cents per proof gall., or 45 cents per gall. of 90% alcohol. This cost could not be materially reduced. The production of alcohol on the farm is only practicable in exceptional cases, since cattle fed upon the distillery slop produce meat which becomes flabby when kept, and must therefore be used for immediate consumption. In 1912 the Minnesota Agricultural Exper. Station tried the experiment on a large scale under favourable conditions, and found that they were unable to produce alcohol as cheaply as they could buy it. Another source of alcohol is "black strap" molasses, which 5 years ago was sold at 2 cents per gall. at the sugar house, but now costs 12 to 14 cents per gall., whilst it now contains less sugar and yields a much lower proportion of alcohol. From black strap molasses of good quality at 5 cents, alcohol could be produced at about 10 cents per proof gall., but it is estimated that the total raw material available in U.S.A. and Cuba would produce only 162,000,000 galls. of alcohol or 5% of the total requirements for motor fuel. Two plants are engaged on the production of alcohol from sawdust in U.S.A., but it is questionable whether they would continue to work if it were not for the present high price of alcohol. Sulphite liquors from pulp mills are a cheap source of alcohol, and at the present time about 3 plants in America are producing alcohol in this way. None of the present processes, however, is entirely satisfactory. Important factors in the production of alcohol from low-grade material are fuel and water supply. In the case of sulphite liquor, which, as concentrated for fermentation, usually contains 4% of hexose sugar, the resulting solution will contain theoretically 2.61% of alcohol, but in practice about 2.2%. The theoretical heat of distillation per lb. of 80% (by vol.) alcohol from such a solution is 4000 B.Th.U., or about 180,000 B.Th.U. per gall.; and for this purpose about 10 to 14 lb. of a good coal would be required, which at a cost of \$3.00 per ton, would make the cost of distillation 1.5 to 2.4 cents per gall. In like manner the cost of distilling 80% alcohol from sorghum juice, containing 15% of hexose, would be 0.4 to 0.6 cent per gall., with coal at the same price. Should the mash require cooking, as, e.g., when starch is present, the B.Th.U. as calculated for the distillation may be multiplied by the factor 2.5, whilst the fuel required for pumping, etc., in a grain distillery is about 50% of the total quantity used. The amount of water required to condense 100 galls. of 80% alcohol and to cool it to 85° F. (29° C.) will be from 900 galls. at 55° F. (13° C.) to 1250 galls. at 80° F. (27° C.). Assuming the liquid as prepared for fermentation to contain 10% of fermentable matter, the following table shows the maximum permissible cost per lb. of fermentable matter for producing alcohol of any given cost per proof gall., allowing a yield of 85%:—

1.2	1.4	1.6	1.8	2.0	2.2	2.4	2.6	2.8	3.0
11.2	12.6	14.2	15.7	17.2	18.7	20.2	21.8	23.3	24.4

Yeast; Process for the treatment of —. J. A. Stevenson. Burton-on-Trent. Eng. Pat. 106,531. May 25, 1916. (Appl. No. 7465 of 1916.)

YEAST, particularly brewers' yeast, is mixed in fine suspension with a large volume of water; any free acid is neutralised by the addition of sodium carbonate or bicarbonate. The liquid mixture is strained and treated with sodium chloride in order to increase the density of the liquid and facilitate the separation of the heavy impurities from the yeast. When the solids have settled, the supernatant liquid is drawn off in such a way as to avoid disturbing the sediment, *e.g.*, by arranging a discharge pipe a certain distance above the bottom of the vat. The process of stratification may be repeated in two or three successive receptacles. In one of the latter a solution of formaldehyde and calcium carbonate may be added to precipitate the tannin and eliminate or reduce the colouring matter. In another receptacle the liquid is treated with oxygen either by electrolysis or otherwise and the yeast is finally separated from the suspension. A yeast suitable for bakers' use may be prepared by blending 35–40% of treated brewers' yeast with 65–60% of distillers' yeast.—J. F. B.

Beer, etc.; Manufacture of dry extracts of —. H. Heuser. Chicago, Ill. U.S. Pat. 1,228,917. June 5, 1917. Date of appl., Dec. 20, 1916.

EXTRACTS which can be converted into beverages of low alcohol-content by dilution with water, are claimed, containing dry extract of a fermented beverage, dry fermentable carbohydrates, and dry living yeast.—J. H. L.

XIXa.—FOODS.

Rennet; Experiments on the preparation of home-made —. A. Todd and E. C. V. Cornish. J. Board Agric., 1917, 24, 307–312.

By slightly varying the conditions of preparation given previously (this J., 1916, 1077), rennet extracts may be prepared having a strength approximating to that of the usual commercial extract. Fifteen split and washed vells are placed in one gall. of brine containing 2 oz. of boric acid; after about 10 days the liquid is separated, the mucous membrane is scraped off the vells and returned to the liquid, whilst the vells are placed in 0.5 gall. of fresh brine. The first steep is tested from time to time until it attains a suitable strength, then filtered and stored in a dark place. The second steep yields a weaker extract. The strength of the extract frequently increases during storage, whilst the number of lactose-fermenting organisms present decreases.—W. P. S.

Pepsin; Experiments with — to replace rennet. D. W. Steuart. J. Board Agric., 1917, 24, 313–315.

FURTHER experiments (see this J., 1917, 664) with pepsin as a substitute for rennet showed that pepsin is much more sensitive to slight differences in the ripeness of the milk than is rennet. One oz. of soluble pepsin powder (1 to 3000) will coagulate 300 galls. of well-ripened milk, but only 75 galls. of fresh milk.—W. P. S.

Plums; Conserving surplus — by drying. J. V. Eyre and S. T. Parkinson. J. Board Agric., 1917, 24, 275–287.

ALL large plums may be dried successfully at 70° to 80° C., either in a current of hot air or in a vacuum apparatus; about 25 hours is required for the drying in hot air and 18 hours in the vacuum process. Preliminary treatments, such as steaming, pricking, and exposure to chloroform vapour, decrease the time of drying, but the plums require subsequent treatment in order to improve their texture. The best results are obtained by treating the plums with chloroform vapour, then drying them, and heating them in a closed vessel with a limited quantity of steam for a few hours. No appreciable advantage is gained by immersing the plums in 1% sodium carbonate solution before drying.—W. P. S.

Lavulose in apple juice; Proportion of —. J. R. Eoff, jun. J. Ind. Eng. Ch. m., 1917, 9, 587–588.

THE juice was expressed from 15 varieties of American and five varieties of French apples ripe for market. The juice from the American apples contained from 7.9 to 12.0% of sugars, comprising from 7.6 to 31.2% of sucrose, 52.5 to 74.7% of lavulose, and 5.0 to 37.6% of dextrose. In the case of the French apples the juice contained from 9.1 to 13.8% of sugars, consisting of sucrose 2.1 to 29.5%; lavulose 58.2 to 74.2%; and dextrose 12.3 to 23.7%. In every instance the amount of lavulose exceeded the combined amounts of the other sugars present.—C. A. M.

Fish; New freezing process for preserving —. E. Kallert. Z. Fleisch und Milchhygiene. Berlin, 1916, 26, 353–355. Bull. Agric. Intell. 1917, 8, 627–628.

THE fish are first refrigerated in ice-cold water, and are then transferred to a salt solution which is far from being saturated at the temperature (–15° C.) at which the process is carried out. Such a solution cannot lose salt to the fish, but will rather absorb more salt. A minimum quantity of salt thus penetrates the skin and subjacent flesh, which were found to contain 0.24 to 0.42% NaCl as against 0.1% of natural salt content. In a basin of 2 cub. metres capacity 197 cwt. of fish can be frozen in 24 hrs. The fish should be kept at –7° C. until required for use.—E. W. L.

Bread; Manufacture of —. W. J. Mellersh-Jackson. London. From Ward Baking Co., New York. Eng. Pat. 106,726, Aug. 9, 1916. (Appl. No. 11,269 of 1916.)

DOUGH is placed in a mixer with revolving arms and adapted to withstand high pressure. Compressed oxygen is pumped in at a pressure of 80 lb. per sq. in. for 3 mins., or compressed air (80 lb. per sq. in.) for 10 mins., or air at a pressure of 20 lb. for 20 mins. Subsequently the dough is fermented. The bread obtained is improved in whiteness. Only 50% of the usual amount of yeast is required, and there is a saving of sugar amounting to 1% of the weight of the flour in the dough.—J. H. J.

Drying [fruits and vegetables]; Apparatus and process for —. O. Q. Beckworth and O. J. Hobson. Seattle, Wash. U.S. Pat. 1,228,283. May 29, 1917. Date of appl., May 11, 1915.

THE material is placed on supports in a chamber and is heated to a temperature below that at which harmful chemical change takes place, by circulating a moist drying medium around the

supports. The heating is continued by radiation from radiators fixed at various points on the walls of the chamber and heated from outside. A current of air is circulated through the materials, and the moisture air is removed from the upper part of the chamber.—W. H. C.

Coffee product and method of making the same. W. J. Ewing, Roland Park, Md., Assignor to The Coffee Products Co. U.S. Pat. 1,229,052, June 5, 1917. Date of appl., Dec. 22, 1916.

ROASTED pulverised coffee is treated with superheated water in a closed vessel to form a liquid extract, which is concentrated to a syrup. A small percentage of water-soluble tapioca starch is added, and the mixture is dried.—J. H. J.

XIXB.—WATER PURIFICATION; SANITATION.

Nitrates [in water]: Determination of — in the presence of chlorides. W. F. Gericke. J. Ind. Eng. Chem., 1917, 9, 585—586.

THE loss of nitrates caused by the presence of chlorides in the colorimetric method with phenoldisulphonic acid, occurs when the reagent is added to the residue from the evaporated solution. Complete evaporation of the solution may be obviated by adding sulphuric acid to the aqueous solution. About 50 c.c. of the solution (containing 1 to 5 parts of nitrate per million) is treated with 1.5 c.c. of strong sulphuric acid, with constant stirring, and then with 2 c.c. of the phenoldisulphonic acid reagent, and the liquid is concentrated first on the water-bath and finally at a temperature not exceeding 70° C. to a quantity of 6 or 7 to 12 or 14 c.c., according to the amount of nitrate present. When concentrated to the necessary degree the liquid will be of a pale yellow colour; it should not be dark in colour or turbid. It is then diluted with about 50 c.c. of water, neutralised with alkali (care being taken to avoid an excessive rise of temperature), and the colour compared with that of a standard solution, which may have been made either by the old method of total evaporation to dryness before the addition of the reagents, or by the modified method described above.—C. A. M.

Nitrates in waters rich in magnesium salts: Determination of — by the phenolsulphonic acid method. M. S. Nichols. J. Ind. Eng. Chem., 1917, 9, 586—587.

ON neutralising the excess of phenolsulphonic acid, hydroxides of iron and magnesium are precipitated, and must be separated by filtration before the colorimetric comparison can be made. In the absence of iron hydroxide filtration may be obviated by adding a sufficient quantity of an ammonium salt to keep the magnesium in solution. If ammonia has been used for the neutralisation, 5 c.c. of a saturated solution of ammonium chloride will keep in solution the amount of magnesium present in 20 to 50 c.c. of most waters, but if sodium or potassium hydroxide has been used, a larger quantity of the ammonium salt will be

required, according to the amount of alkali used in excess. The ammonium salt is added after the neutralisation and before the final dilution.—C. A. M.

Strontium and lithium: Determination of — in water. S. D. Averitt. J. Ind. Eng. Chem., 1917, 9, 584—585.

STRONTIUM.—The weighed oxides of calcium and strontium, as obtained in the official method of the Assoc. Off. Agric. Chemists (U.S.A.), are dissolved in hydrochloric acid, and reprecipitated as oxalates. The precipitate is separated, washed with 0.5% ammonium oxalate solution, and finally with three successive portions of 5 c.c. of cold water, and titrated with N/10 potassium permanganate solution. The amount of oxides taken for the titration should not exceed about 0.03 grm. The amount of strontium oxide may then be calculated by means of the equation: $W - \text{CaO equivalent of permanganate titration multiplied by } 2.179 = \text{SrO}$, where W = weight of CaO and SrO.

LITHIUM.—The weighed chlorides of sodium, potassium, and lithium, as obtained in the official (Gooch) method, are dissolved in water, and aliquot portions are used for the determination of the potassium (and hence of the KCl), and of the total chlorine. The weight of LiCl may then be found as follows:—NaCl equivalent of total chlorine—Cl in KCl—(total weight of mixed chlorides—KCl) multiplied by 2.64 = LiCl. Accurate results were obtained in the determination of strontium and lithium in test solutions by these methods.—C. A. M.

Sterilisation of liquids in thin layers. H. Stassano. Comptes rend., 1917, 165, 41—43.

THE liquid is forced by the uniform pressure of a compressed inert gas, such as nitrogen, through a heating vat formed by two plane metallic surfaces separated by a paper frame at a distance of about 0.01 mm. In this way the liquid is raised to the desired temperature as rapidly and regularly as possible, and after a very short interval of heating is rapidly cooled. The short period of exposure to the heat enables bactericidal changes to be brought about in milk or in serums and toxins, without causing chemical decomposition of the main organic constituents.—J. N. P.

Disinfection of tannery wastes. Jackson and Buswell. See XV.

PATENTS.

[Water] filters; Outlet or extraction pipes of —. J. J. Lassen and V. F. Hjort, London. Eng. Pat. 106,512, Mar. 21 and May 12, 1916. (Appl. Nos. 4183 and 6797 of 1916.)

IN extraction or outlet pipes for filters, a hemispherical cup is mounted on the pipe in the filtering chamber and communicates with it through an opening in the bottom. The cup carries radial arms projecting outwards level with the top, and a perforated metal disc larger than the cup is laid on the top. The whole is covered by a conical hood so that sand or other filtering medium is diverted away from the perforated disc, and the discharged liquid passes upward through the annular part of the perforated disc, and then downward through the central part and through the cup into the extraction pipe. In a modification, the cup may be replaced by a trough and the hood may project over one or both sides, or two separate hoods may be used meeting at the centre. In another modification, the troughs may be formed by ridges projecting upward from the bottom of the filtering chamber.—W. F. F.

Water; Apparatus for the softening and purification of—. [Cleansing filtering material.] J. J. Lassen and V. F. Hjort, London. Eng. Pat. 106,514, Mar 30 and May 12, 1916. (Appl. Nos. 4694 and 6798 of 1916.)

FILTERING material which has been used for filtering water after this has been softened by treatment with lime, etc., is cleansed by increasing the flow of water through the material and agitating by a current of air or steam, or both. Various arrangements are described for carrying out the process.—W. P. S.

Sterilisation of liquids by ozone; Apparatus for—. J. Steynis, Bay Shore, N.Y.. Assignor to Steynis Ozone Co. U.S. Pat. 1,228,712, June 5, 1917. Date of appl., Nov. 24, 1914.

THE apparatus consists of a mixing tank into which liquid is injected with a rotatory movement. Gas is also supplied to the injector, and a safety reservoir is provided to prevent liquid from entering the gas supply in case of a failure in the means for supplying the liquid.—J. H. J.

Silver compound of the acridin series [disinfectant] and a process of making same. P. Hüsey and M. Hartmann, Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,227,624, May 29, 1917. Date of appl., Jan. 23, 1917.

COMPOUNDS of value as disinfectants are obtained by the action of a soluble silver salt, in presence of a solvent, on acridine dyestuffs which may be alkylated at the acridine nitrogen. Special claim is made for the silver compound of 2·7-dimethyl-3·6-diamino-acridine, methylated at the acridine nitrogen. It is a brownish-red powder, forming coloured solutions in water, alcohol, acetone, ethyl acetate, acetic acid, and sulphuric acid. It acts as a disinfectant in solutions of great dilution, strongly checking the growth of bacteria, especially streptococci and splenitis bacilli.—J. H. J.

Water, sewage and the like; Treatment of—. S. H. Menzies, London. Eng. Pat. 106,914, Sept. 1, 1916. (Appl. No. 12,401 of 1916.)

CHLORINE gas under pressure is allowed to diffuse through plates of spongy carborundum into the liquid flowing along a pipe. The excess of chlorine is removed farther along the pipe by sulphur dioxide gas diffusing into the liquid, in a similar manner. To oxygenate the liquid and to remove excess of sulphur dioxide, the liquid is passed through a filter containing manganese zeolite, activation of the zeolite being effected by the sulphur dioxide present.—J. H. J.

Water, sewage, and the like; Treatment of—. S. H. Menzies, London. U.S. Pat. 1,229,305, June 12, 1917. Date of appl., Sept. 27, 1916.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Amygdalin; Constitution of—. A. Bau. Biochem. Zeits., 1917, 80, 159—162.

EXPERIMENTS on the decomposition of amygdalin by *Saccharomyces Ludwigii* Hansen, which does not secrete maltase, were undertaken to gain an insight into the nature of the sugar component of amygdalin. Tests by Kluijver's method (Biochem. Suikerbepalingen, Leyden, 1914), in which the dextrose is estimated from the volume of carbon

dioxide formed by fermentation, indicated that in 3% solution the amount of dextrose formed corresponds to the decomposition of over 54% of the glucoside. In experiments with larger quantities of the glucoside, also in 3% solution, the formation of hydrocyanic acid was demonstrated in quantity equivalent to the decomposition of a little over 2% of the glucoside into hydrocyanic acid, benzaldehyde, and dextrose. These results indicate that the yeast contains another enzyme, amygdalase, in addition to emulsin (see Caldwell and Courtauld, this J., 1907, 885), and that amygdalin does not contain a maltose group (compare Fischer, this J., 1895, 877) but another disaccharide which yields 2 mols. of dextrose (see Auld, this J., 1907, 437).

Silver salt-proteins compound. Changes in the physical condition of colloids. XXI. W. Pauli and J. Matula. Biochem. Zeits., 1917, 80, 187—210.

SOLUTIONS of glutin (purified gelatin) and albumin were treated with silver nitrate and the amount of silver fixed by the protein was determined by electrometric and electrical conductivity measurements. In both cases the amount of silver fixed increased with the concentration of the silver nitrate (at first rapidly and then slowly in the case of glutin) until a constant value was attained: the maximum quantity of silver combined with 1 gm. of the protein was about $2·3 \times 10^{-4}$ gm.-equivalent for glutin and 5×10^{-4} for albumin. Similar results were obtained when casein was suspended in silver nitrate solution. The silver-salt glutin compound yields unaltered glutin when subjected to prolonged dialysis, and both it and the albumin compound migrate to the anode under the influence of an electric current, whilst compounds of proteins with salts of heavy metals such as iron, chromium, etc., migrate to the cathode. The silver can be partially displaced from the complexes by treatment with alkali or alkaline-earth salts, an equilibrium being established. Comparison with previous results indicates that in the compounds of proteins with alkali, alkaline-earth, and silver salts, the anion and cation of the salt are fixed in equivalent quantities. The coagulation of albumin by heat is retarded or inhibited in presence of silver nitrate.

Alpinia nutans, Roscoe; Volatile constituents of leaves of—. K. Kafuku. Kogyo-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 319—353.

THE leaves of *Alpinia nutans*, Roscoe, contain 0·053% of a volatile oil of sp. gr. 0·9301 at 19° C., $n_D^{20} = 1·4750$, $n_D^{25} = 1·4750$, $n_D^{30} = 1·4750$, $n_D^{35} = 1·4750$, $n_D^{40} = 1·4750$, $n_D^{45} = 1·4750$, $n_D^{50} = 1·4750$, $n_D^{55} = 1·4750$, $n_D^{60} = 1·4750$, $n_D^{65} = 1·4750$, $n_D^{70} = 1·4750$, $n_D^{75} = 1·4750$, $n_D^{80} = 1·4750$, $n_D^{85} = 1·4750$, $n_D^{90} = 1·4750$, $n_D^{95} = 1·4750$, $n_D^{100} = 1·4750$. Saponification value 9·88, saponification value after acetylation 36·1. The chief constituents of the oil are *d*-camphor (more than 30%) and *d*-camphane (17%). Other constituents are cineol and an ester of cinnamic acid, and probably limonene, a sesquiterpene, and a high-boiling phenol.

Oil of wine; Heave—. R. Kremann. Monatsh. Chem., 1917, 38, 53—62. J. Chem. Soc., 1917, 112, i, 314.

WHEN 2·5 parts of concentrated sulphuric acid and 1 part of ethyl alcohol are distilled on a sand-bath, a product is obtained which settles into two layers. The lower layer is a yellow, oily liquid, formerly termed heavy oil of wine. This consists mainly of ethyl sulphate, but contains a small quantity (5%) of unsaturated hydrocarbons of the olefine series. On shaking with warm water, the whole of the ethyl sulphate is hydrolysed to ethyl hydrogen sulphate, which passes into solution, whereas the hydrocarbons remain undissolved. The hydrocarbon oil, after drying, boiled at 286° C. and had sp. gr. 0·921. On keeping, a solid, crystalline substance separated, of sp. gr. 0·980.

m. pt. 100° C., b. pt. 260° C.; this also is an olefine. Molecular weight determinations by the cryoscopic method (in acetic acid) and by the ebullioscopic method (in ether) showed that the liquid hydrocarbon has a mean molecular weight of 221, corresponding to $C_{16}H_{32}$. Experiments on the hydrolysis of the crude ethyl sulphate in aqueous, acid, and alkaline solutions, led to the conclusion that the crude ethyl sulphate prepared as above is not a mixture of ethyl sulphate and unsaturated hydrocarbons, but rather a mixture of ethyl sulphate and a compound of ethyl sulphate with the unsaturated hydrocarbons.

Acetone: Compounds of calcium chloride and —.
L. S. Bagster. Chem. Soc. Trans., 1917, 111, 491—497.

ACETONE, dried by several successive quantities of dehydrated calcium chloride, has been shown to combine with the latter substance, forming $CaCl_2 \cdot 2C_3H_6O$, and by placing this in an exhausted vessel connected to a pump, the compound $CaCl_2 \cdot C_3H_6O$ is formed. Analyses and determinations of the vapour pressures have confirmed the existence of these substances as definite compounds, which are stable up to 130° C.—B. N.

Calcium glycerophosphate. J. F. Conch. Amer. J. Pharm., 1917, 89, 243—251.

COMMERCIAL calcium glycerophosphate is essentially a mixture of isomeric α - and β -calcium glycerophosphates, the isomerism being that of substituted propyl and isopropyl groups. The solubility of the compound in water at 25° C. is 1 in 31.6 parts, but is decreased by the presence of alcohol, glycerol, or sodium glycerophosphate, the solubility in 12% alcohol being 1 in 66.6. Lactic, citric, and phosphoric acids, and sodium citrate increase the solubility even in the presence of alcohol or glycerol, but the compound undergoes hydrolysis by the action of the acids. Alcohol and glycerol retard the hydrolysis, but the use of acids in order to increase the solubility of the compound is undesirable. Many compound mixtures of glycerophosphates contain quinine, and weak organic acids produce an intramolecular change in the quinine with the production of quinotoxine, a highly poisonous ketone.—W. P. S.

Cyanamide: Constitution of —. E. Colson. Chem. Soc. Trans., 1917, 111, 554—561.

Two possible structural formulae have been suggested for cyanamide: the normal formula $N:C:NH_2$ and the carbodi-imide formula $NH(C:NH)$. The constitution of the dialkyl-amides has been clearly established and the author has studied the refractometric constants of cyanamide in comparison with those of its dialkyl derivatives on the one hand and of carbodi-propylimide on the other. The values obtained for the CN_2 group in cyanamide and three of its alkyl derivatives were found to agree very well with the calculations made from Eisenlohr's atomic refractivities, and since the dialkyl cyanamides are known to have the constitution $N:C:NR_2$, it follows that cyanamide possesses a similar structure.—J. F. B.

Alcohols: Identification of —. E. E. Reid. J. Amer. Chem. Soc., 1917, 39, 1219—1255.

WHEN alcohols are heated with phthalic anhydride the corresponding acid phthalic esters are obtained and the sodium salts of these esters, on heating with *p*-nitrobenzyl bromide, give mixed phthalic esters which may be used for the identification of the alcohols, since they have definite melting points. About 1 gm. of the alcohol is heated for 1 hour with 1 gm. of phthalic anhydride, primary alcohols being heated in a sealed tube at 100° C., and secondary alcohols in an open tube at 140° C.; the mixture is then diluted with

water, rendered alkaline with sodium hydroxide, and shaken with ether. The aqueous layer is separated, evaporated to dryness, and the residue is boiled for 1 hour under a reflux condenser with 5 c.c. of water, 10 c.c. of 95% alcohol, and 1 gm. of *p*-nitrobenzyl bromide; the product obtained is recrystallised from 63% alcohol, and its m. pt. determined. The following mixed phthalates have been prepared and their m. pts. are given:—Methyl *p*-nitrobenzyl phthalate, 105.7° C.; ethyl *p*-nitrobenzyl phthalate, 80° C.; propyl *p*-nitrobenzyl phthalate, 53.0° C.; isopropyl *p*-nitrobenzyl phthalate, 74° C.; allyl *p*-nitrobenzyl phthalate, 61.5° C.; *n*-butyl *p*-nitrobenzyl phthalate, 62.0° C.; *n*-octyl *p*-nitrobenzyl phthalate, 41.0° C.; benzyl *p*-nitrobenzylphthalate, 83.0° C.; phenylethyl *p*-nitrobenzyl phthalate, 84.3° C.; bornyl *p*-nitrobenzyl phthalate, 100° C.; isobornyl *p*-nitrobenzyl phthalate, 87° C. The method may be used for the detection of methyl alcohol in the presence of ethyl alcohol, ethyl alcohol in admixture with ethyl benzoate or menthol, and borneol in camphor.—W. P. S.

PATENTS.

Ureas or thioureas of the naphthalene series; Manufacture of —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Leverkusen, Germany. Eng. Pat. 20,192, Sept. 25, 1914.

UREAS and thioureas are prepared from:—(1) 1,8-aminonaphtholsulphonic acids by the action of nitroacyclic carboxylic acid chlorides, chlorides of nitroxyl fatty acids, nitronaphthoyl chlorides, or nitronaphthalene sulphochlorides, and, after reduction of the nitro-group, treatment with phosgene for the introduction of the carbonyl group; (2) from naphthylaminesulphonic acids by the action of aromatic nitroacydihalogenides, completing the process as before; and (3) from naphthylaminesulphonic acids or aminonaphthol sulphonic acids by the action of aromatic nitroacydihalogenides, completing the process by reduction of the nitro-group and introduction of the CS group from thiophosgene. The new compounds have a germicidal action on blood parasites, although harmless to the body containing them. They may be used for the production of substantive cotton dyestuffs.—J. H. J.

Di[hydr]pyridiaminoarsenobenzene; Metallic derivatives of —. J. Danysz, Sèvres, France. Eng. Pat. 104,196, July 10, 1916. (Appl. No. 9677 of 1916.) Under Int. Conv., Feb. 29, 1916.

THE compounds obtained from 4,4'-dihydroxy-3,3'-diaminoarsenobenzene and mercury salts are difficult to use therapeutically, since they are only slightly soluble in dilute acids, and decompose when soda is added. If, however, they are treated with antimony compounds, antimonyl derivatives are obtained which are more soluble, stable in alkaline solution, more active, and less toxic. *Example.*—10 grms. of 4,4'-dihydroxy-3,3'-diaminoarsenobenzene in 100 c.c. of methyl alcohol, is mixed with 4 grms. of antimony chloride in 4 c.c. of methyl alcohol and 1 gm. of mercuric iodide in 90 c.c. of methyl alcohol. A clear cherry-red solution is produced from which ether precipitates a yellowish-red powder containing the antimonyl group, easily soluble in water and in dilute soda. The soluble sodium compound is precipitated from the solution in caustic soda by adding ether.—F. Sp.

Oxydianilinoarsenobenzene; *Metallic derivatives of* —. J. Danysz, Sèvres, France. Eng. Pat. 104,497, July 10, 1916. (Appl. No. 9678 of 1916.) Under Int. Conv., Feb. 29, 1916.

ONE mol. of 4,4'-dihydroxy-3,3'-diaminoarsenobenzene hydrochloride is treated in aqueous solution with 1 mol. of a freshly prepared silver halide, and 1 mol. of antimony trichloride is dissolved in the solution by heating; to the resulting solution is added a concentrated solution of citric acid; dilute sulphuric acid is then added to precipitate the base. The silver salt may be replaced by the salts of gold, platinum, or copper. The stable products obtained are much more antiseptic and relatively less toxic than the parent substance. —F. W. A.

Salicylic acid vapour; *Condensation of* —. R. J. Pugh, Southall, Middlesex. Eng. Pat. 106,516, Apr. 20, 1916. (Appl. No. 5789 of 1916.)

FOR the condensation of salicylic acid vapour when mixed with steam, the mixed vapours are passed into a condensing chamber having a wall, part or the whole of which is pierced by capillary interstices permeable to the steam, so that condensation of the salicylic acid and its separation from the steam occur on the inner permeable wall of the chamber and the acid falls down in a powdery condition. The condensing chamber is preferably constructed with a wooden framework, without iron or other metals, and a woven material, such as woollen canvas, is stretched over the framework to form a permeable wall on which the crystals of salicylic acid are condensed and deposited. —J. F. B.

Lyxyllic acid or its compounds; *Process of making* —. M. Vaygouny, Berkeley, Cal., Assignor to Royal Baking Powder Co. U.S. Pat. 1,227,706, May 29, 1917. Date of appl., July 23, 1910. EE Fr. Pat. 456,156 of 1912; this J., 1913, 959.

Iodo-2,3-dihydroxypropane and process of making same. R. Lüders, Steglitz, Assignor to Farb. vorm. Meister, Lucius, u. Brünig, Höchst, Germany. U.S. Pat. 1,230,185, June 19, 1917. Date of appl., June 15, 1915.

EE Eng. Pat. 8488 of 1915; this J., 1916, 489.

Formaldehyde; *Process for the manufacture of crystalline polymerisation products of* —. F. Pollak, Vienna. U.S. Pat. 1,230,600, June 19, 1917. Date of appl., Nov. 21, 1913.

EE Eng. Pat. 25,830 of 1913; this J., 1914, 218.

XXII.—EXPLOSIVES; MATCHES.

Nitrocellulose; *A product of the deflagration of* —. E. Trapani. Atti R. Accad. Lincei. 1917, 26, I., 332—334.

WHEN a few centigrams of a nitrocellulose powder (cellulite, cordite, etc.) was heated in a test-tube until deflagration occurred, a pungent odour, resembling that of formaldehyde, was observed, and on adding water and sodium carbonate to the

contents of the tube and applying Rimini's test with phenylhydrazine hydrochloride and sodium nitroprusside (this J., 1898, 697), an intense coloration was obtained, indicating the presence of a notable quantity of formaldehyde.

PATENTS.

Smokeless powder; *Process of manufacture of* —. Westfälisch-Anhaltische Sprengstoff-A.G., Berlin. Ger. Pat. 296,591, Mar. 16, 1913.

IN order to increase the stability and plasticity of the powder, anilides of organic acids are added in which the imide hydrogen is replaced by a radicle, with the exception of ethyl or methylacetanilide. These anilides are particularly suitable as camphor substitutes, and owing to their lower volatility have a favourable effect on the stability of the powder. —J. F. B.

Impregnating solids with liquids of very low boiling point [e.g., liquid oxygen]; *Apparatus for* —. L. Sieder, Munich. Ger. Pat. 297,225, June 9, 1915. Addition to Ger. Pat. 295,270 (this J., 1917, 238).

THE steeping vessel, closed either at the bottom or the top and insulated against heat, is arranged inside the reservoir for the liquid, which is closed at the top and likewise insulated, and taps are situated in the reservoir or in both vessels whereby pressure may be applied to drive the liquid into or out of the steeping vessel. A cartridge holder is provided in which the cartridges are arranged one above the other and which can be put in or taken out when required. —J. F. B.

XXIII.—ANALYSIS.

Nichrome-constantan thermocouple; *Notes on the* —. R. W. Woodward and T. R. Harrison. U.S. Bureau of Standards. Met. and Chem. Eng., 1917, 16, 647—648.

THE thermocouple No. 18 nichrome—No. 12 constantan can be used in air up to 1000° C. even when only partly protected, and retains its constancy to within 10° C. until the constantan is nearly completely oxidised. The E.M.F. of the couple is quite high (63·8 millivolts at 1000° C.). —W. H. P.

Crystals; *The drainage of* —. N. F. Hall, J. Amer. Chem. Soc., 1917, 39, 1118—1152.

WHERE substances are being separated by crystallisation, the mother liquor may be drained off the crystals by simple gravitational drainage, or more efficiently, by means of a centrifugal machine. By means of one centrifugal draining a degree of separation may be attained which would otherwise require a number of recrystallisations. The author has calculated the equivalence of these two methods of drainage on certain assumptions. A table is given of the number of crystallisations with gravitational drainage such that one-fourth of the mother liquor remains adhering to the crystals, which will be necessary to secure the same degree of purity as one crystallisation followed by centrifuging where all but 0·008 of the mother liquor is removed. It includes values corresponding to the whole range of conditions of solubility of the dissolved bodies. —H. J. H.

Precipitates; *Contamination of* — *in gravimetric analysis. Solid solution and adsorption versus higher order compounds*. G. McP. Smith. J. Amer. Chem. Soc., 1917, 39, 1152—1173.

THE author seeks to show that the contamination of precipitates by soluble salts, during analytical operations, is due to the formation of complex insoluble salts and not of solid solutions or of adsorption products. As an example the retention of iron by barium sulphate precipitated from solutions containing iron under various conditions

of precipitation is considered. The iron was introduced in the form of disulphato-ferrie acid (ferri-sulphuric acid), $\text{Fe}_2(\text{SO}_4)_3 \cdot 11\text{H}_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$, which in solution in water behaves as a mixture of sulphuric acid and ferric sulphate. On the addition of barium chloride, the barium salt, $\text{Ba}[\text{Fe}(\text{SO}_4)_2]_2 \cdot n\text{H}_2\text{O}$ is held to be formed and carried down with the precipitate. On standing this complex is slowly dissociated with the liberation of barium sulphate. As this will probably be of an extremely fine-grained character it will cause the development of a slimy and impervious type of precipitate often found in the determination of barium sulphate.—H. J. H.

Molybdates, tungstates, and vanadates of cobalt-ammonium compounds; Use of— in determination of cobalt. A. Carnot. *Comptes rend.*, 1917, 164, 897—902. (See also Schoeller and Powell, this J., 1917, 720.)

THE complex cobalt-ammonium compounds have been studied in connection with the analytical separation and determination of cobalt. To a solution of cobalt containing ammonium chloride, ammonia and then hydrogen peroxide is added. The solution passes through a series of colour changes, becoming dark brown and then, with the evolution of oxygen, purple, red, or pink. In the cold, this requires 1 hour with concentrated solutions and much longer with dilute. A few minutes suffices if gentle heating be applied, but the solution must not be boiled or decomposition to the luteo-compound with precipitation of cobalt will occur. In this way a solution of purpureo-cobaltamine chloride $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$ is produced. The cobalt is then precipitated as the corresponding molybdate by just neutralising the ammonia and adding a slight excess of 5% ammonium molybdate solution. After settling for some time the precipitate is filtered through a tared filter and washed with water. The precipitate is insoluble in water but soluble in ammonia, and dilute acids; hence the need for careful neutralisation. The precipitate is weighed after drying at 110°C . and then has the composition $\text{Co}_2\text{CO}_3 \cdot 10\text{NH}_3 \cdot 6\text{MoO}_4$. The corresponding tungstate and vanadate are similarly prepared but are not so suitable for analytical purposes. Cobalt may be separated from nickel by precipitation as described, but a reprecipitation of the molybdate is necessary if the nickel predominates in the mixture treated. The nickel is then estimated by known methods. The reaction may be used in separating cobalt from zinc, cadmium, or copper, but is only to be recommended where the cobalt alone is to be estimated, as the presence of molybdate introduces complications in the determination of the other metals.—H. J. H.

Arsenic; New method of destroying organic matter preparatory to the detection of—. A. Gautier and P. Clausmann. *Comptes rend.*, 1917, 165, 11—16.

THE method of destroying animal or vegetable organic matter by means of nitric and sulphuric acids is tedious, and it is necessary to precipitate the arsenic as sulphide and again bring it into solution before introducing it into the Marsh apparatus. The following method requires much less time, and experiments have shown that quantitative results are obtained even with minute quantities of arsenic. The substance is heated at about 300°C . until it swells and becomes friable. It is then ground in a porcelain mortar with 2—3% of pure quicklime (from marble or calcium nitrate), which is slaked with a small quantity of water; the mixture is placed in a shallow porcelain capsule which is introduced into a small muffle furnace, and the furnace is heated to dull redness; the mixture swells somewhat at first and then burns slowly like tinder. After cooling, the residue is powdered, treated with

water, a slight excess of sulphuric acid added, and the solution heated to boiling and filtered. The insoluble residue is washed, and the filtrate and washings are concentrated until white fumes appear, then diluted with 8—10 times its volume of water, and introduced into the Marsh apparatus (see this J., 1902, 1472; 1903, 903).

PROHIBITED EXPORTS.

An Order-of-Council, dated 14th August, 1917, orders that the Schedule to the Proclamation, dated 10th May, 1917, as amended by the Orders-of-Council of 22nd June and 13th July, prohibiting the exportation from the United Kingdom of certain articles to certain or all destinations,* should be amended, as follows:—

The following headings are deleted:—(A) Zinc oxide; (B) Zinc sulphide; (A) Cylinders, metal, such as can be used for containing compressed gas; (A) Tanning extracts, and substances for use in tanning.

The following headings are added:—(A) Ethylic alcohol, mixtures and preparations containing (not otherwise prohibited); (A) Zinc oxide, and mixtures containing zinc oxide; (A) Zinc sulphide, and mixtures containing zinc sulphide; (A) Cylinders, metal, capable of use for the storage of gases or liquids under pressure; (A) Oil, shark, and mixtures containing such oil; (A) Colza or rape seed oil and articles and mixtures containing such oils; (A) Tanning extracts and substances for use in tanning, including cutch.

EXPORTS TO SWITZERLAND.

An Order-of-Council, dated 10th August, 1917, orders that the Schedule to the Proclamation, dated 13th March, 1917, prohibiting the exportation from the United Kingdom of certain articles, and any articles composed wholly or partially of those articles, to any destination in Switzerland, should be amended as follows:—

The following headings are deleted:—Bitumen. Curriers' crystalline grease. Glucose, solid. Naphtha; naphthylamine (alpha and beta naphthylamine); naphthol (alpha and beta naphthol) and similar products; naphthalene and its compounds. Platinum. Steel, special, containing nickel, chrome, molybdenum, vanadium, tungsten, titanium and other alloys, including tools (except watchmakers' tools), machine parts and all articles in special steel; scrap, filings and waste of special steel; edge tools in ordinary steel. Turpentine. Varnishes, gum.

The following headings are added:—Benzonaphthol. Bitumen and bituminous compositions. Cardboard, asphalted. Cassava root. Celluloid wares. Citrate of lime. Curriers' grease. Degras. Felts, asphalted. Glucose. Glucose, solid, for the manufacture of artificial silk. Insulating materials. Liqueur wines containing a higher percentage of alcohol than that indicated in the Swiss Tariff. Mosses, Iceland, Irish (Carrageen), and Sphagnum. Naphtha; naphthol; naphthalene; naphthylamine and similar products. Paper, Japanese, and similar paper. Platinum in all forms, including manufactures (except platinum jewellery). Salophene. Steel, special, containing

0.5% of nickel, chrome, or tungsten, 0.2% of molybdenum, 0.1% of vanadium or titanium, 9% of manganese, 0.5% of cobalt (stellite), including tools (except watchmakers' tools), machine parts and all articles in special steel; scrap, filings and waste of special steel; edge tools in ordinary steel. Tin wares, including alloys. Turkey red oil, and other sulphuric acidates. Turpentine and mixtures containing turpentine. Varnishes of all kinds. Waxed and oiled cloth. Wines in casks, or otherwise than in bottles. Wood spirit.

EXPORTS FROM THE UNITED STATES.

A Proclamation has been issued by the President of the United States providing for the control by licence of exports from that country, and it is notified in the 23rd July issue of the official "Commerce Reports" (Washington) that the Exports Council has authorised the publication of the following list comprising articles determined to be included under the general headings mentioned in the Proclamation referred to. Additions may be made to this list if it is determined that other articles are properly included in the general headings given in the Proclamation. Export licences are, therefore, required at present for any article included in the following list:—Coal. Coke. Fuel oils—Lubricating oil; benzol; head lantern oil; toluol; naphtha; benzine; red oil. Kerosene and gasoline, including bunkers. Oil cakes and oil-cake meal. Malt. Cottonseed oil. Corn oil. Copra. Coconuts, desiccated. Grease, inedible or edible, of animal or vegetable origin. Linseed oil. Lard. Tinned milk. Peanut oil and butter. Rapeseed oil. Tallow. Tallow candles. Stearic acid. Pig iron. Steel billets:—Steel sheet bars; steel blooms; steel slabs. Scrap iron and scrap steel. Ferro-manganese. Cattle manure, shredded. Nitrate of soda. Poudrette. Potato manure. Potassium salts. Land plaster. Potash. Cyanamide. Phosphoric acid. Phosphate rock. Superphosphate. Chlorate of potash. Bone meal. Bone flour. Ground bone. Dried blood. Ammonia and ammonia salts. Acid phosphate. Guano. Humus. Hardwood ashes. Soot. Sheep manure, pulverised. Anhydrous ammonia. Nitrate of potash. Resin. Sulphur. Saltpetre. Turpentine.

SUPERPHOSPHATE PRICES.

The Minister of Munitions has made an Order as follows, under date 20th August:—

1. As on and from the day following the date of this Order the maximum prices for superphosphate shall be as follows:—

(a) In the case of sales or purchases for delivery in railway trucks at purchaser's or consumer's siding or nearest railway station or on barge or ship at purchaser's or consumer's wharf or in the case of sales or purchases for shipment to the Channel Islands, f.o.b. at port of shipment, the prices specified in the Schedule hereto, but less a discount or deduction of 2s. 6d. per ton on sales of two tons and upwards by makers or producers to manure mixers, agricultural merchants and dealers, and co-operative societies registered under the Friendly Societies Acts.

(b) In the case of sales or purchases for delivery at maker's or producer's works free into purchaser's or consumer's carts or wagons for conveyance direct by road to consumer's premises, the prices

* The prohibition of exports is as follows:—

Goods marked (A), to all destinations;
Goods marked (B), to all ports and destinations abroad other than ports and destinations in British Possessions and Protectorates;

Goods marked (C), to all destinations in foreign countries in Europe and on the Mediterranean and Black Seas, other than France and French Possessions, Russia, Italy and Italian Possessions, Spain and Portugal, and to all ports in any such foreign countries, and to all Russian Baltic ports.

specified in the Schedule hereto, less 10s. per ton.

(c) In the case of sales or purchases for delivery ex vendor's store or shop or ex warehouse, railway goods yard or public wharf, the prices specified in the Schedule hereto with the addition of the following amounts according to the quantity of superphosphate included in the sale or purchase, namely:—

Quantity sold and purchased.	Additional price authorised.
4 tons and over	5s. per ton.
1 ton and over but less than 4 tons	10s. "
2 cwt. and over but less than 1 ton	1s. per cwt.
Less than 2 cwt.	2s. "

Provided that such additional prices shall not be charged or paid in the case of sales or purchases of more than one ton for delivery ex railway goods yard or public wharf.

(d) In the case of sales or purchases for delivery by road at consumer's premises from vendor's store or shop or from warehouse, railway goods yard or public wharf, the maximum prices authorised under paragraph (c) above plus cost of or local rates for cartage or haulage.

2. The maximum prices fixed by paragraphs (a) and (b) of clause 1 of this Order shall not apply to any sale or purchase by or from a maker or producer for delivery as mentioned in those paragraphs where the quantity of superphosphate included in the sale or purchase is less than two tons; and none of the provisions of clause 1 hereof shall apply to any sale of superphosphate for export from the United Kingdom. But save as aforesaid no person shall as on and from the day following the date of this Order until further notice effect or offer to effect any sale or purchase of superphosphate except for delivery in accordance with the terms specified in one or other of subparagraphs (a), (b), (c) and (d) of clause 1 of this Order and at a price not exceeding that prescribed by the said clause and the Schedule hereto as the maximum price (having regard to quantity, quality and date for and terms of delivery) for such sale or purchase.

3. The maximum prices fixed by clause 1 of this Order are *net* prompt prices for superphosphate in maker's or vendor's bags. Where credit is given to the purchaser a reasonable extra charge may be made provided that a price for net prompt cash is quoted on the invoice and does not exceed the maximum price authorised. If purchaser's bags are used, a reasonable allowance shall be made.

4. All persons engaged in producing, manufacturing, selling, distributing or storing superphosphate, or in any manufacture in which the same is used, shall make such returns with regard to their businesses as shall from time to time be required by or under the authority of the Minister of Munitions.

5. All provisions of the Fertilisers and Feeding Stuffs Act, 1906, and the regulations made by the Board of Agriculture and Fisheries in pursuance of the provisions of that Act, shall apply *mutatis mutandis* to this Order.

For the purposes of this Order, superphosphate shall mean superphosphate of lime manufactured from mineral phosphate, but shall not include basic superphosphate, bone superphosphate, dissolved bones, bone meal or bone compound, guanos or compound manures.

NOTE.—All applications in reference to this Order should be addressed to the Director of Acid Supplies, Ministry of Munitions, Department of Explosives Supply, Storey's Gate, Westminster, London, S.W.1, and marked "Fertilisers."

The Schedule.

Maximum prices for superphosphate referred to in clause 1 of the above Order:—

Percentage of tribasic phosphate of lime rendered soluble in water:—15% or over but less than

16%, £4 12s. 6d.; 16—17%, £4 15s.; 17—18%, £4 17s. 6d.; 18—19%, £5; 19—20%, £5 2s. 6d.; 20—21%, £5 5s.; 21—22%, £5 7s. 6d.; 22—23%, £5 10s.; 23—24%, £5 12s. 6d.; 24—25%, £5 15s.; 25—26%, £5 17s. 6d.; 26—27%, £6; 27—28%, £6 2s. 6d.; 28—29%, £6 5s.; 29—30%, £6 7s. 6d.; 30—31%, £6 10s.; 31—32%, £6 14s.; 32—33%, £6 18s.; 33—34%, £7 2s.; 34—35%, £7 6s.; 35—36%, £7 10s.; 36—37%, £7 14s.; 37—38%, £7 18s.; 38—39%, £8 2s.; 39—40%, £8 6s.; 40—41%, £8 10s.; 41—42%, £8 14s.; 42—43%, £8 18s.; 43—44%, £9 2s.; 44% or over but less than 45%, £9 6s. per ton.

The above prices for all qualities are for orders placed for delivery during December, 1917. In the case of orders placed for delivery during other months, the above prices are in each case to be reduced or increased 1s. per ton per month according as the month for delivery precedes or is subsequent to December, 1917, but with a maximum increase of 5s. per ton, e.g., the prices for October, 1917, deliveries will be 2s. less per ton, while the prices for May and June, 1918, deliveries will be 5s. more per ton than the prices set out above.

Yorkshire Section.

Meeting held at Queen's Hotel, Leeds, on Monday, March 12th, 1917.

PROFESSOR J. W. COBB IN THE CHAIR.

DISCUSSION ON THE SOFTENING OF WATER.

Mr. G. H. FRANK opened the discussion with a short paper in which he enumerated the chief methods of softening water, by the use of lime, sodium carbonate or caustic soda, permuto, or combinations of these, and gave brief descriptions of some types of softening plant, including those of Archbutt and Deeley, Paterson, Collet, Wilson, and Lassen and Hjort. The paper was illustrated by a number of photographs.

The CHAIRMAN referred to various problems that arose in connection with water-softening plants, and the distribution of softened water from them. The modern tendency was to automatic addition of the chemicals required, but it was obviously necessary to secure accuracy, and such difficulties as the clogging of measuring-buckets, and the irregularities in the content of suspensions, and the alteration in diameter of measuring apertures had to be faced. Moreover when water supplies were liable to serious fluctuations in composition, the applicability of any automatic appliance became questionable and the softening of large volumes in tanks of the Archbutt-Deeley type more practicable. In connection with the permuto process arose the liability of a perfectly softened water to initiate or aggravate corrosion of service-pipes and boilers, and also the tendency to "priming" in the boiler of a water heavily laden with sodium salts. It was sometimes debatable as to whether in a large establishment central softenings followed by distribution through pipes was better or worse than the use of separate plants for particular installations. "Furring" of the pipes undoubtedly occurred at times and it was debated as to how far carbonating of the softened water to prevent this was convenient and effective. The disposal of the mud of lime salts from a softening plant was sometimes a problem.

Mr. F. W. RICHARDSON said that the permuto process worked well under certain given conditions, and it was very desirable that waters to be treated

should be free from iron. A preliminary treatment with lime and soda ash did not remove iron from all waters. It was, indeed, suggested that the iron in waters should be passed through manganese-permutite, which always oxidised any ferrous salt, and completely removed the per-salts so formed. One objection to the use of permutite with waters containing much calcium carbonate was the production of an alkaline effluent which affected certain light shades in dyeing, and some firms had been obliged to resort to neutralisation—a rather delicate matter. The use of barium carbonate had been suggested. If this salt were effective, in conjunction with magnesium and calcium sulphates, it would form insoluble barium sulphate and also the relatively insoluble calcium and magnesium carbonates, whereas in the lime and soda process much sodium sulphate was left in solution, and after concentration in the boiler had to be blown off from time to time.

Mr. B. G. McLELLAN emphasised the need for proper chemical control of water-softening plant, and quoted figures to show that the softeners did not take their full share of the softening process, and that, in some cases, a large excess of chemicals was entering the boilers. He had had experience with a water softener in which the softening medium used was milk of lime and sodium carbonate. Troubles due to uneven solution of the lime and to the presence of gritty particles were overcome by breaking up these particles in the chemical preparation tank. It was found to be advantageous to agitate the water after the addition of chemicals, before sending it to the main tank for settling. A baffled trough ("Salmon-ladder") was provided, which was later increased in length with beneficial results. The removal of the precipitated matter presented many difficulties; a large proportion of this settled in the main tank, and was sludged away at intervals, the remainder being caught in the wood-wool filter in the upper part of the tank. With the water in question, the filter soon filled up, and required frequent flushing and periodical removal for cleaning. He had frequently noticed that the softening was not so complete for some time following the packing of the filter with new wood-wool. Experiments had been made to elucidate this, the results of which showed that the intimate contact of the water with the precipitate on the wood-wool caused the reactions to proceed to a point nearer completion. The water was softened from 31 grains to 5 or 6 grains per gallon. No scale formed in the boilers, but the economisers had to be cleaned periodically. As was to be expected the feed water contained a large quantity of sodium sulphate and precautions had to be taken to prevent the water in the boiler becoming too concentrated.

Mr. P. E. KING said that he had had considerable experience with the Lassen and Hjort automatic softening machine, and also with the permutite process. The permutite process in his opinion dealt for softening crude water and the quantity of solids left in solution was not so objectionable as in water previously softened with lime or lime and soda, which contained free lime and was a source of constant annoyance in filling up pipes, valves, etc. This deposit in pipes was due to a secondary reaction between the free lime and the residual temporary hardness and was accelerated by heat. Permutite was used for softening town's water. There was one installation softening 50,000 galls. per day of 20° hardness to zero and then mixing with an equal quantity of hard water, thus bringing the hardness down to 10°. The sodium bicarbonate produced exerted no action on the remaining hardness. Manganese permutite was largely used for sterilising water, and calcium permutite could be used for the removal of free lime to some extent. He preferred the

milk of lime and soda process to clear saturated lime water, the former being more adjustable to range of speed of softening. Unfortunately permutite was proved to be spoilt by passing water of too great alkalinity through it, and this happened when a previous softening of the water with lime or lime and soda took place and the resultant water was very alkaline. The deterioration of the permutite in this case was slow and did not occur in all cases of alkaline water. In his opinion, a great deal more should be known with regard to the action of various waters on permutite. At the present time permutite plants were being installed to remove the remaining hardness after the lime and soda treatment. This was the ideal system, both from initial cost standpoint and from results obtained.

Mr. A. PENDLEBURY said that he had designed an apparatus for keeping milk of lime in suspension by agitation and lifting it to the softening plant. The apparatus consisted of two tanks driven by belts for mixing the milk of lime; a centrifugal pump connected to the two tanks lifted the milk of lime to the top tank on the softening plant which was designed with a semicircular bottom. The end of the delivery pipe was fan shaped, causing a rapid flow along the bottom of the top tank. About two to three times the quantity of lime picked up by the plant and necessary for softening the water was pumped and the surplus fell back to the mixing tank.

Dr. H. INGLE said that he had had experience with several plants, including the Archbutt-Deeley, and Watson and Birkett, but he always found difficulties owing to the variation on the water from day to day if it came from a stream and the variation of the composition of the lime caused by the exposure to air and other causes. To overcome these troubles each tank ought to be tested, and all lime should be kept in airtight receptacles and analysed. The preparation of a constant "milk of lime", was difficult, and he approved of Mr. Pendlebury's appliance. The use of colloids in the boiler to prevent the formation of scale was very old. Tannin refuse, potatoes, and other substances of a colloidal character had been used. Their effect was to render the deposition of crystalline substances impossible, and to produce an amorphous deposit, and they had been found effective. Complaints had been made in Leeds that during the last twelve months a great increase of boiler scale from the River Aire water had resulted. A considerable amount of soap was present in the water and this was probably the cause of the varnish-like surface of the total solids. Sulphates were high, due no doubt to the use of nitre cake in place of sulphuric acid in the neutralisation of scouring liquors, and also to the effluent from munition works.

Mr. B. A. BURKELL did not think it desirable completely to soften waters that were intended for a town's supply, or for boiler purposes; if for the former, there would probably be an outbreak of plumbism, and for the latter purpose he had had several of these completely softened waters which had attacked boiler plates rather badly owing no doubt to the water containing much carbon dioxide which had not been removed by treatment.

Mr. W. HARRISON stated that sand did not act catalytically but chemically in a similar manner to permutite, although to a much less extent. He suggested that the effect of tannins in preventing boiler scale was due to colloids other than tannic acid, which are always present in vegetable tannins.

Mr. H. G. BENNETT speaking from a tanner's point of view, indicated that the excess of alkali remaining in water softened by the permutite process was a fatal defect when tan liquors were to be made with the softened water. One of the great difficulties with aill processes yet suggested

was that the reactions were incomplete, and that the later stages of softening took place after the water had left the softener—in pipes, tanks, and boilers. This difficulty seemed to be greater when larger proportions of magnesia were present, and in some cases it would appear that the magnesia remained in colloidal solution. He supported Dr. Ingle's suggestion that variations in the quality of the lime were another cause of difficulty, and he had found that the only way to obtain satisfactory results was to have the softened water tested, at least once each day, and also to make tests of water actually taken from the boilers. He suggested that it was desirable that chemists not only had better agreement in the methods of testing, but also in the method of reporting results. It was high time that such terms as "degrees of hardness" and "grains per gallon" made a final disappearance. With regard to a recent paper by Kay and Newlands on the "Determination of Hardness of Natural Waters, and the use of methyl red as indicator" (this J., 1916, 415), he pointed out that the methods were not altogether new. He had himself used methyl red for temporary hardness determinations for some years, and had published the method (Collegium 1915, 237, Lon. Edition; see this J., 1915, 1028). He had found it an exceedingly satisfactory indicator. With reference to the use of organic matter in boilers, he supported Mr. Harrison's suggestion that the extractive matters rather than the tannins were the useful ingredients, and mentioned that some tanners ran their spent tan liquors into the boilers.

Mr. THORP WHITAKER mentioned that the permute process of softening was taking place naturally around Bradford. Natural zeolites occurred in certain districts and water obtained from such strata was very soft and contained a certain amount of alkalinity, which for instance in Bradford was very constant in composition, and greatly appreciated for wool-scouring purposes. Instances had been known in well sinking in the Bradford district where the water was first struck it was exceedingly hard, and on sinking lower through the strata natural zeolites were found and the water from below this was exceedingly soft and contained large quantities of sodium carbonate.

Mr. S. EVANS said that his experience of a large number of waters, used for boilers in connection with turbo-generator sets, was that is no single instance was the water properly softened. He also knew of a large well which delivered water alkaline to phenolphthalein. He agreed that the best method was to soften the water to 5 or 6 degrees, and then use an organic boiler compound in the boiler. His theory of the action of these organic boiler compounds was that they increased to a very great extent the surface tension of the water, and thus prevented deposited matter from interlocking to form an incrustation. The suggestion to use barium carbonate to give two insoluble compounds by double decomposition was excellent, except for the fact that barium carbonate was insoluble, and therefore the reaction would be inefficient; the grains of barium carbonate would become covered with a coating of sulphate, which would prevent further action. He had had experience of similar material becoming coated with calcium sulphate and had been able to dissolve out the soluble interior, leaving the thin shell of calcium sulphate intact. He agreed that the best method of keeping lime was to slack it to a pug. Lime was never properly burnt, and when allowed to air-slake or slaked with a minimum of water, the heap contained somewhere about 40% of free lime. One speaker had referred to the action of "baffle plate" and "salmon ladder" mixers for promoting the reactions. In his opinion this was exactly the action of sand, wool-wool, and permute in enhancing

the reactions. The percolation of the solution through the exceedingly fine interstices of these materials was a most efficient and thorough method of mixing them. He mentioned the case of a boiler feed water containing 33 pts. per 100,000 of total solids of which 6 pts. per 100,000 was sodium; after continuous steaming for three months the boiler water contained 844 pts. per 100,000 total solids of which 26 pts. was sodium; the boiler crust from the above contained 60% chloride.

The following table was interesting as showing the state of the water in some boilers.

Source of sample.	Pts. 100,000.	
	Total solids.	NaCl.
Before boiler	207	170
Boiler contents, after 5 days	5743	5174
Blow-off	9814	8643

In conclusion he cited an instance of a water containing 1657 pts. per 100,000 NaCl being used for cooling in a surface condenser.

THE LOW TEMPERATURE DISTILLATION OF INFERIOR COALS.

BY T. F. WINMILL, B.A., B.SC.

(Research Chemist to the Staveley Coal and Iron Company, Ltd.)

(COMMUNICATED.)

Accompanying the main coal seams in some parts of England are often found seams of inferior coal substances, which with different composition and in different districts receive different names, such as "Jacks," "Branch Coal," "Bastard Cannel." As the last name implies, these coals have often some resemblance to a cannel coal, but this resemblance is not very close. They are all distinguished by their high ash content, and the very voluminous nature of the ash, making them useless for ordinary fuel purposes. Jacks and black shale may leave 80% of ash when burnt, whilst a very good sample of bastard cannel may leave only 10%. Where they occur, considerable quantities of these coals have to be raised with the main coal, and form an expensive waste product, not only from the cost of raising, but because waste tips must be provided on the surface, forming unsightly heaps which often fire either spontaneously, or from other causes.

In some districts the bastard cannel is fairly uniform in composition over a wide area and contains generally between 20 and 30% of ash. The associated carbonaceous matter is intermediate in composition between a "soft" coal and a cannel, as is shown by the following limiting analyses, calculated on a dry, ash-free basis:—

	78	%	81
Carbon	5.7	"	6.0
Hydrogen	1.2	"	1.5
Nitrogen	1.5	"	5.0
Sulphur	10.0	"	10.1
Oxygen			

From these figures it is clear that the substance contains a large amount of potential energy which is at present wasted. The carbonaceous portion is comparable in composition to that of a good coal, so that in effect every 100 tons of branch or bastard cannel coal contains as much heat value as 70—80 tons of high grade coal.

Experiments have been made therefore to see whether any portion of this potential energy can be made available in the form of oil fuel or other valuable products.

Of recent years much attention has been given to the destructive distillation of coal at low

temperatures, and many accounts have been published of the results of such distillations. In general it is claimed that very large yields of tar and ammonia are obtained by this method—much larger than those from coke ovens or gas retorts—and further that the tars on re-distillation yield useful oils of different grades, some sufficiently volatile to replace petrol as a motor spirit. Such a process seemed therefore admirably suited for extracting the greatest possible quantity of valuable products from the branch coal. As the sequel shows, expectations of a large yield of oils have not been realised, and no workable quantity of volatile oils corresponding to petrol was recovered, despite the fact that a cannel coal should on the showing of previous publications have been the most favourable substance with which to work.

Apparatus. In designing the apparatus for the distillation, it had to be borne in mind that the coke residuum would in any case be valueless as its ash content would be above 50%. The aim of the design had to be, therefore, to secure the most rapid coking, with the biggest possible yield of by-products, without considering the effect on the residuum. The retort was made of cast iron two inches thick, built into a fire-brick chamber,

and heated by five evenly placed Bunsen burners. It held a charge of 8 cwt. of coal and was fitted with a very efficient stirrer working through a vacuum-tight stuffing box. The stirrer quickly ground up the charge and brought fresh portions of it continually against the hot walls of the retort, thus securing a rapid heating throughout the mass, instead of depending on the slow conduction of heat usual in any other coking oven. The distillation was carried out under a vacuum of from 26 to 28 inches of mercury, and had gone as far as it would at 500° C. in 3½ hours, after which the contents of the retort could be discharged by opening the bottom door and reversing the direction of revolution of the stirrer.

Whilst effecting such a marked shortening in the time of coking, the stirrer introduced experimental difficulties which at first gave much trouble. Part of the charge was, by the combined action of the stirrer and the effect of the temperature, quickly reduced to a fine dust which was carried out of the retort, blocking the ascension pipes and the condensers. To reduce this to a minimum the speed of the stirrer was reduced from 3 revolutions per minute to 2 revolutions in three minutes, but even at this speed the condensers became choked,

DIAGRAM.

Arrangement of coal distillation plant, *Slaveley Coal and Iron Co., Ltd., old works.*

until a dust-catcher and other appliances for dealing with the dust were introduced. An interesting, though very objectionable, property of this dust was its extreme liability to spontaneous combustion. A few pounds of it removed from the ascension pipe, even when absolutely cold, would by the absorption of oxygen from the air, and the consequent spontaneous generation of heat, burst into flame within about half an hour. The exclusion of oxygen from the dust prevents, of course, this firing.

The other details of the apparatus need no special remark, and are quite clear from the figure drawn by Mr. F. Smith, for whose assistance in the arrangement, building, and working of the plant the writer wishes to tender his best thanks.

Method of working. The retort was brought to a temperature between 500° and 550° C., the stirrer started, and a charge of 8 cwt. of coal introduced from a hopper. The retort door was then closed, and the valve leading to the vacuum pump opened. The whole charging operations occupied less than 5 minutes. The vacuum and a temperature of 500° C. were maintained for 3½ hours, at the end of which time experience showed that practically no more oils or gases were being evolved. The vacuum valve was then closed and air admitted to the retort through a ½ in. pipe from the bottom of the charge. The bottom door of the retort was then opened, the direction of revolution of the stirrer reversed, and the carbonised residue discharged from the retort in the space of a few minutes. The collected tar was then run off from the condensers, after which the apparatus was ready for another charge. The complete series of operations, from the introduction of one charge to the introduction of the next, occupied slightly less than four hours, so that a plant of the size described would be capable of dealing with nearly 2½ tons of coal per day of 24 hours.

Distillation products. The distillation produced (1) tar and aqueous liquor condensed *in vacuo*; (2) gas which passed through the vacuum pump and was in part burnt under the retort.

Treatment of tar. The vacuum tar was quite fluid when warm but on cooling became as viscous as ordinary coke-oven tar. It has a characteristic and not unpleasant odour, quite unlike that of the latter. About 30 gallons was produced per ton of coal distilled. Its separation from the admixed water is very difficult and nothing approaching a complete separation of the two could be obtained by "settling," or by reheating and settling.

On re-distillation it undergoes decomposition even at temperatures as low as 150° C., depositing carbon and evolving hydrogen, sulphuretted hydrogen, and ammonia, the two latter gases probably coming from the admixed water, which in addition causes much frothing. Distillations were carried out both at ordinary pressure and under vacuum, but the products of the two distillations did not differ materially. The residue in the still consisted of a hard pitch which had to be chipped out. The distillate was a very dark-coloured oil containing suspended carbon, apparently formed partly by the thermal decomposition of the original tar and partly by oxidation of the cold oil. In this state chemical treatment of the oil was difficult and it was therefore subjected to a further distillation, when it left as a residue a semi-solid mass containing much free carbon, and furnished a distillate which was at first colourless, quickly becoming red and finally within a day black. This behaviour was not confined to any one fraction, all the distillates between 150° C. and 360° C. appearing to discolour with equal rapidity. The various fractions were then treated with 10% caustic soda solution. All the fractions yielded a soluble portion, varying in amount. Thus, for example, the oil distilling up to 180° C. yielded 18%, that between 200° and 220° C. 47%, whilst

that between 330° and 360° C. yielded only 21% soluble in the soda solution. Of the whole distillate 33% was dissolved. The remaining 67% on re-distillation gave a colourless oil which, however, soon blackened again. Treatment with successive portions of strong sulphuric acid finally gave an oil which on distillation remained colourless or only slightly yellow.

That part of the oil soluble in caustic soda consisted of a complex mixture of phenolic substances, but contained practically no phenol (carbolic acid). The simplest phenols present were the three cresols, and these were mixed with higher homologues and phenolic ethers containing non-esterified hydroxyl groups. The whole mixture can only find very limited uses similar to those of coal-tar creosote.

The fraction soluble in sulphuric acid consisted of a mixture of neutral phenolic ethers together with some hydrocarbons.

The "working up" of the vacuum tar followed therefore the following plan:

The quantitative results per ton of coal distilled were:—

Pitch	100 lb.
Semi-solid wax	50 lb.
Soda-soluble oil	4 gallons.
Phenolic ethers, extracted by sulphuric acid..	1.5 gallons.
Hydrocarbon oil	6.5 gallons.

The finally purified hydrocarbon oil formed the main bulk of the liquid products. It consists of a mixture of unsaturated and polymethylene hydrocarbons from which no chemical individual could be easily separated. The mixture has a characteristic and not unpleasant odour; it starts to boil at 150° C. and continues to distil in fractions of fairly equal volumes, for equal temperature rise up to 360° C., above which point about 5% of the total remains unvolatilised. The various fractions range in density from 0.794 to 0.910 at 15° C. No benzenoid hydrocarbons are present, and no commercially valuable compound can be isolated from the mixture. Even the higher boiling point oils are mobile liquids, and possess neither sufficient viscosity nor "body" for use as lubricants. The only obvious use for the mixture is as a fuel oil.

Ammonia production. The bulk of the ammonia formed was contained in the condensed aqueous liquor, and was equivalent to about 25 lb. of ammonium sulphate per ton of coal. A further quantity of 10—15 lb. can be extracted from the gas leaving the condensers, giving a total yield of about 35—40 lb. of ammonium sulphate per ton of coal.

Gas. The gas coming from the condensers is very similar in composition to ordinary coal gas, and contains very little extractable light oil. Some oil is carried mechanically with the gas, but no appreciable quantity of oil boiling below 150° C. could be obtained, either by condensation or by washing. About 6000 cubic feet of gas was produced per ton of coal distilled.

Conclusions. The experiments described show definitely that low-temperature distillation of a high-ash waste coal is not a commercially economical process. The initial low cost of the waste coal would at first sight seem to make it possible to work on comparatively small yields of by-products. It must not be forgotten, however, that in ordinary coking practice the price obtained for the coke made, as a rule, more than pays for the

slack from which it is made, and hence in the absence of coke from the waste fuels the apparent advantage of worthless coals more than disappears, and the whole costs of the process have to be defrayed by the increased value of the by-products. In previously published accounts the quantity and nature of these products claimed have been sufficient to pay for the process, but in the light of the experiments now described it would appear that these have been estimated too optimistically. The saleable products amount to 6 gallons of oil, 35—40 lb. of ammonium sulphate, and perhaps 2000—3000 cub. ft. of gas after allowing for that necessary for the distillation.

The value of the oil is difficult to estimate, as it is of a new type. It would seem to have little value except as a fuel oil, and for that purpose need not perhaps be so highly purified. Unless fairly complete purification is made, however, the oil will resinify and become of much less utility. The cost of complete purification is considerable. The phenolic substances which it is desired to remove are not very readily soluble in soda, being much weaker acids than carboic acid, and hence the partition coefficient between the oil layer and the soda layer is so large that a considerable number of washings with comparatively large volumes of soda solution are necessary. In practice it is found that a total volume of 10% soda solution equal to the volume of the oil washed, is necessary for the complete removal of the phenolic bodies. The cost of these washings, added to that of the distillations, would make it impossible to produce the refined oil at a profit in normal times. As a fuel, however, the crude unwashed oil might find a market, but in this state it could only compete with coal tar creosotes, for which the uses are limited and the price low.

It was thought that possibly by "cracking" the oil, benzenoid compounds might be obtained in sufficient quantity to make the distillation profitable, but small-scale experiments in which the oil vapours were passed over coke at 800° C. gave no encouragement for larger experiments.

It must be concluded, therefore, that low-temperature distillation cannot be made to pay on the value of the by-products alone, and hence is useless as a means of utilising waste fuels of high ash content. The process as applied to valuable coals is in somewhat a different position, for in this case a residue of "smokeless" fuel is obtained. At present it cannot be claimed that there is any very large market for such fuel in competition with coal itself, but what market may be created in the future it is impossible to estimate. Legislation in favour of smoke abatement would of course give a great impetus to the use of semi-carbonised fuels, since most boilers and all domestic fireplaces are not designed to burn ordinary coke, whereas the semi-carbonised fuels obtained by the low-temperature distillation of coal can often be burnt more or less successfully in existing apparatus, but they would then find a severe competitor in gas firing. Unless such measures are taken, however, the ease with which a coal fire can be maintained, and the smaller proportion of ash in a good coal (for by carbonising the proportion of ash in the residuum is made nearly double that in the coal from which it is produced), will severely handicap the extended use of smokeless fuel.

Annual Meeting.

MANUFACTURE OF SYNTHETIC NITRATES BY ELECTRIC POWER.

BY E. KILBURN SCOTT.

(See this Journal, July 31, 1917, 771—777.)

In a written contribution to the discussion, Captain C. J. Goodwin submitted that while every

credit was due for Mr. Scott's valuable work, it should be noted as a matter of interest that Dr. Helbig, of Rome, had previously developed and patented the use of a three-phase current in similar furnaces (see this J., 1908, 576, and Norton, Utilization of Atmospheric Nitrogen U.S. Department of Commerce, Special Agents Series No. 52, 1912, 92). Had the Bonecourt system of packing with refractory material boiler tubes such as those provided in Mr. Scott's furnace been tried? In this way, the rapidity of cooling, regenerative yield, and efficiency of the boiler should be increased. It was a popular fallacy that it was essential for the gases to travel upwards in absorption towers as usually designed. Particularly in the case of nitric oxide, the density of which is approximately that of the atmosphere, it was not only permissible, but, in theory, there was a slight advantage, if the gases travelled alternately upwards and downwards, as when the gases travelled in the same direction as the absorbing liquid, there was a slight increase in the time of contact, particularly if the packing was so designed that an appreciable time was required for the liquid to travel from the top to the bottom of the tower. The Moscicki system was not equally suitable in cases where the density of the gases differed appreciably from that of the atmosphere. A condition for efficient absorption was not necessarily a maximum of contact surface. In the present case, the main factors were ample time for oxidation, contact, and reaction, together with merely sufficient surface to absorb the higher oxides at the same rate as they were formed. In addition, adequate mixing was essential and this could only be efficiently obtained by continuous throttling and expansion, causing change of velocity. These conditions were not attained by quartz pebbles, which, moreover, themselves occupied so great a percentage of the volume of the tower that the velocity of the gases over the absorbing surfaces was excessive unless the section and volume of the tower were made greater than in cases where packing designed on scientific principles was used. He had himself used, about six years ago, the principle of alternate oxidation and absorption together with periodic flushing in a block of towers of rectangular shape. Horizontal instead of vertical flow for the gases was ingenious, but very few good filling materials were suitable, as they were usually designed for a flow of gas and liquid in the same direction, whereas in the Moscicki towers the liquid descended vertically and the gases moved horizontally. A modified form of ring filling of double conical shape, arranged irregularly, would be suitable and would give a large "free space" together with adequate surface and a good mixing action.

Communication.

ESTIMATION OF NITROGEN IN NITRO COMPOUNDS.

BY A. P. SACHS.

The recent paper by Colver and Prideaux (this J., 1917, 480) on the determination of NO_2 in nitro compounds by reduction with stannous chloride, indicates that the results already obtained in a research which has unfortunately been interrupted may prove of value. The problem was to determine the nitrogen content of a large number of samples of nitrated "solvent naphtha." For this the Dumas combustion method takes too much time. Cope's modification of the Kjeldahl method (J. Ind. Eng. Chem., 1916, 592; this J., 1916, 907) is highly satisfactory for nitrotoluenes and picric acid, but proved unsatisfactory for the material under investigation, giving low and erratic results.

The method of reduction with stannous chloride and determination of the excess of reducing agent by iodine titration in alkaline tartrate solution was found unsatisfactory. Reduction and titration under practically the conditions described by Colver and Pridaux (*loc. cit.*) gave results considerably too low and not concordant enough for use even as a comparative method. The cause of the low results obtained by these investigators and by ourselves is to be found simply in the incomplete reduction of the nitro compound under the conditions used. More strenuous reducing conditions must be sought. A modification of the method adopted by us gave excellent results in certain cases. The method adopted was to carry out the reduction in a sealed tube at 120° C. for 2 hours. Excellent results were obtained with mononitrobenzene, *m*-dinitrobenzene, mononitroxymerene, and with certain of the nitrated "solvent naphthas," but the problem cannot be considered as definitely solved. In this reaction each nitrogen atom (present as NO_2) is equivalent to six iodine atoms, or 1 c.c. of $\text{N}/10$ iodine solution is equivalent to 0.0002335 gram of nitrogen.

Procedure. About 0.2 gram of the sample, weighed to 0.0001 gram, is placed in the "tube." (If the sample is liquid the Lunge pipette is conveniently used for weighing the substance.) The "tube" is made of thin-walled glass tubing about $\frac{3}{4}$ inch in diameter, about 8 inches long, sealed at one end. 15.00 c.c. of the stannous chloride solution (made by dissolving 350 grms. of $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ in 700 grms. of 25% HCl) is then run in from a burette. Owing to the large normality factor of this solution as compared with the iodine solution used it is essential that the same amount of stannous chloride solution be employed for each determination and for the blank. Any solution which may adhere to the side of the "tube" is washed down with a fine stream of water from a wash bottle and the tube sealed in the blast flame and allowed to cool. A set of tubes and two blanks (as a tube improperly annealed sometimes cracks in the oven, though the pressure developed is so low that no breakage occurs with properly annealed tubes), properly marked, are heated in a constant-temperature oven at 120° C. for 2 hours, and shaken every 15 minutes. When the sample is not shaken dark particles due to carbonisation or the deposition of tarry matter sometimes occur. After the heating is completed the tubes are allowed to cool, standing in a rack, a file-mark made near the end, and the tip of the tube broken off. The contents of the tube are washed into a 100 c.c. flask, diluted to the mark, and 10 c.c. taken for titration. In all cases separate aliquot portions agree to within one drop of iodine solution. The liquid is titrated with carefully standardised $\text{N}/10$ iodine solution, using starch as indicator. In our experiments the titration was finished with $\text{N}/100$ iodine, but this is hardly necessary or even advisable. The end-point is sharp and distinct. To avoid if possible the introduction of error, the time of titration was made about equal in all cases, although aliquot portions measured from a burette and titrated without any effort being made to titrate in equal time intervals gave identical results.

(A) Reductions carried out in open flask on steam bath. Titration in acid solution: *Nitrobenzene*. The sample was distilled three times and the end fractions rejected in each distillation. Combustion showed 11.38% N. By reduction, 10.49% and 10.91% N. (In all cases the figures refer to separate reductions, and not to various aliquot portions of the same reduction.) *Nitrated solvent naphtha*. Sample produced on manufacturing scale. Nitrogen by combustion,

14.50%. By reduction, 14.51%, 13.90%, and 12.66%.

(B) Reductions carried out in sealed tubes as indicated in procedure described above: *Nitrobenzene*. Portion of the same material as used for experiment in (A). Preliminary reductions (first set tried with sealed tubes) gave 11.26% and 11.14% N. Another set gave 11.32% and 11.37% N. *Mononitroxymerene*. This material was prepared in an unpublished research and was purified by repeated distillation. It was a mixture of the 1-nitro and 2-nitro compounds. By combustion, 7.89% N. By Cope's modification of the Kjeldahl method (*loc. cit.*), 7.88% N. By reduction, 7.89% and 7.90%.

m-Dinitrobenzene. Good commercial material recrystallised from alcohol. By combustion, 16.67% N. By reduction, 16.38%, 16.63%, and 16.66% N. *Nitrated solvent naphtha A*. Sample produced on a commercial scale by nitrating a solution of naphthalene in solvent naphtha. The nitro compounds contain nitronaphthalenes. By combustion, 13.80% N. By reduction, 12.54%, 13.11%, 13.00%, and 13.01% N. *Nitrated solvent naphtha B*. This sample, as well as samples C and D, were prepared by nitrating solvent naphtha (without dissolved naphthalene) at various temperatures, strength of nitrating acid, etc. By combustion, 13.50% N. By reduction, 13.51%, 13.32%, 13.57%, 13.50%, 13.55%, and 13.48% N. *Nitrated solvent naphtha C*. By combustion, 13.10% N. By reduction, 13.10% and 13.08% N. *Nitrated solvent naphtha D*. By combustion, 13.54% N. By reduction, 13.47% and 13.62% N.

These results show that the proposed modification of the stannous chloride method is suitable as a method for routine analysis, especially where a number of similar samples have to be analysed. In such a case an occasional blank should be run on a sample of known nitrogen content. This will serve to check the standardisation of the iodine solution.

The method is quite rapid, and a dozen or more analyses can be made daily by one chemist, as compared with 3 or 4 determinations per day by one chemist using two electrically heated combustion furnaces. The combustion method as used in this laboratory requires copper oxide free from nitrogen, which takes a long time to prepare, and is very slow for explosive or volatile materials (like nitrobenzene and the nitrotoluenes), but gives the best results obtainable by any method, as duplicates agree usually within 0.05% and seldom differ by as much as 0.10%. On pure control samples of nitrobenzene or picric acid the figures agree within 0.02% to 0.05% of the theoretical nitrogen figure calculated from the formula.

Acknowledgment is made of the assistance of Mr. G. S. Andrews, of this laboratory, in making the actual analyses.

The work reported here was carried out in the Research Laboratory of Aetna Explosives Co.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Ferou 8, Paris (3e.).

Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Oxyhydrogen gas explosions in compressed gas cylinders. L. Wöhler. *Z. angew. Chem.*, 1917, 30, 174—175.

THE author, after referring to the regulations which have been enforced in Germany since 1902 with regard to the filling and use of compressed gas cylinders for oxygen and hydrogen gases, gives details of some recent explosions to show that in spite of all these precautions, accidents, due to carelessness and negligence, are of frequent occurrence. The most disastrous of these, in which three men were killed and many were injured, occurred at Darmstadt. An empty oxygen cylinder, of 210 cub. ft. capacity, was filled with hydrogen, but the error was discovered before the gas was used and the cylinder was returned to the compressed gas works. Without emptying the cylinder, the men in charge of the oxygen filling machinery filled the cylinder to its maximum capacity with oxygen, and when the cylinder arrived at the railway workshops the second time, and was put into use, it burst. The author points out that owing to the shortage of copper the connecting gas couplings used at the filling works are now of iron or steel. The rule with regard to right- and left-handed threads to the cylinder fittings for the different gases is therefore easily evaded, for a steel or iron screw externally threaded when used with a powerful wrench will easily cut its own thread internally on a brass connecting piece whatever the thread may have been on this originally. The regulations with regard to the use of distinctive colours for the cylinders containing the two gases have also been often ignored lately, owing to labour shortage and similar difficulties, and cylinders have been used indiscriminately for oxygen or hydrogen, without regard to their colour or markings. As a precaution against similar accidents and explosions the author recommends the application of the Habber test for explosive gases before the gas from any cylinder is used, or the still more simple soap-bubble test, which consists in blowing a bubble with the gas from the cylinder, and then applying a light. These tests, however, are of little value if left in the hands of the workmen, since negative results can easily be obtained with them.—J. B. C. K.

PATENTS.

Separating solids from liquids: Process and apparatus for—. P. T. Sharples, West Chester, Pa. U.S. Pat. 1,232,104, July 3, 1917. Date of appl., May 6, 1916.

A MIXTURE of two constituents of different specific gravity is separated by mixing it with a carrier liquid of greater specific gravity than the constituents of the mixture and centrifuging the whole. The lighter constituent is discharged through one outlet and the heavier constituent, together with the carrier liquid, through another outlet of the centrifuge. The carrier liquid is then separated and returned to the process.—W. H. C.

Replacing and thickening apparatus. Process of replacement [for treating slimes and pulp]. G. Moore, Joplin, Mo. U.S. Pats. 1,231,409 and 1,231,410, June 26, 1917. Date of appl., Oct. 9, 1914.

THE pulp is passed down and the dissolving

solution and wash water are passed up a vertical, cylindrical vessel provided with groups of superimposed horizontal discs. The solids settle through the solution and collect on the discs and are then disturbed and broken up and again settled through a fresh portion of solution or wash water. The solids collect in the conical bottom of the vessel and the solution overflows at the top.—W. H. C.

Dewatering and replacement apparatus. G. Moore, Joplin, Mo. U.S. Pat. 1,231,411, June 26, 1917. Date of appl., Dec. 11, 1914.

THE pulp flows in one direction and the wash water in the opposite direction through a series of vessels formed by mounting a number of spaced plates in a tank. These plates can be tilted from a position in which the solid particles collect on the plates to one in which the solid particles slide off.—W. H. C.

Liquids; Process of separating the constituents of—. W. A. Schmidt, Los Angeles, Cal., and L. Bradley, East Orange, N.J., Assignors to Research Corporation, New York. U.S. Pat. 1,232,395, July 3, 1917. Date of appl., June 2, 1914. Renewed Mar. 24, 1917.

A MIXTURE of liquids of different degrees of volatility is sprayed into a current of heated gas so that the more volatile liquid is evaporated. The mixture of vapour and particles of less volatile liquid is then passed through an electric field to precipitate the particles.—W. H. C.

Separating air or other gaseous fluid from liquids; Means for—. W. H. Walker, London, Eng. Pat. 107,030, May 10, 1916. (Appl. No. 6706 of 1916.)

TO prevent the escape of vapour along with the air which is discharged from the air-collecting chamber, when the level of liquid in the chamber falls and causes the float-operated valve to open, the connection between the air chamber and the discharge valve is made by a spiral pipe, in which any vapour is condensed, the condensed liquid being returned to the air chamber. The air-escape valve, which is operated by the float and is counter-balanced by a weight, has a passage-way of small cross-sectional area and also a subsidiary valve which only opens when the main valve has moved a certain distance, so that the escape of air takes place in a steady manner.—W. H. C.

Refrigeration and the production of ice; Processes and apparatus for—. W. R. Ormandy, London, W. E. Calvert, Halifax, and The Seay Syndicate, Ltd., Manchester. Eng. Pat. 107,040, June 8, 1916. (Appl. No. 8132 of 1916.)

THE liquid absorbent and/or the liquid product of absorption of the gas used for refrigeration are absorbed by a solid such as kieselguhr, pumice, or a clay-like artificial absorbing material. The product is substantially a solid and is rapidly cooled during the absorbing and rapidly heated during the evolution period.—W. H. C.

Straining or filtering apparatus [for fuel oils]. Vickers, Ltd., London, and J. McKechnie and J. P. Clear, Barrow. Eng. Pat. 107,090, July 8, 1916. (Appl. No. 9665 of 1916.)

A NUMBER of perforated plates having an annular rib on one face, provided with small straining

channels, are fitted together, one above the other, in a casing. The oil is fed under pressure into the interior of the pile of plates and passes through the straining channels into the space between the outer casing and the pile of plates.—W. H. C.

Mixing mill; Continuous —. J. Crossley, Trenton, N.J. U.S. Pat. 1,231,499, June 26, 1917. Date of appl., Feb. 5, 1917.

A NUMBER of mixing-mills, each provided with an agitator and having discharge openings at their lower ends, are connected by conveyors, so that the materials pass from mill to mill.—W. H. C.

Grinding-mill. G. H. Blankmann, St. Louis, Mo. U.S. Pat. 1,231,478, June 26, 1917. Date of appl., Aug. 30, 1916.

GRINDING bars are disposed helically about the ends of radial beaters mounted on a rotating shaft. The distance between the grinding bars and the ends of the beaters is adjusted by means of rotating scroll rings having spiral grooves in which the outer ends of the grinding bars fit.

—W. H. C.

Ball-grinding machine. J. Vorraber, Munich-Trudering, Germany. U.S. Pat. 1,231,818, July 3, 1917. Date of appl., July 29, 1916.

A STATIONARY holder has grooved discs on each side and grinders co-operating with the grooved discs. Grinding balls are fed to and returned from the grooved discs, and the stationary holder is provided with wedge keys, by means of which axial pressure in opposite directions can be exerted by the holder.—W. H. C.

Dryer; Rotary —. N. M. Rosendahl, Winthrop Harbor, Ill., Assignor to F. C. Austin, Chicago, Ill. U.S. Pat. 1,229,524, June 12, 1917. Date of appl., Nov. 5, 1914.

A CURRENT of heated air is drawn through a horizontal rotary drum having several concentric inner cylinders attached alternately to opposite ends of the drum. The material is fed through a hollow trunnion at one end, travels backwards and forwards, and is discharged from peripheral openings in the outer drum.—W. H. C.

Dryer. W. J. Kuntz, York, Pa. U.S. Pat. 1,229,978, June 12, 1917. Date of appl., Jan. 19, 1917.

AN inclined rotary drum has an inner shell connected with a cylindrical shell in one side of the feed head. Heated gas is conveyed by a flue into the opposite side of the feed head and into the shell extension, and air is admitted through an enlarged opening around the flue into the inner shell of the drum.—W. H. C.

Drying apparatus. C. H. Currier, Newark, N.J. U.S. Pat. 1,230,282, June 19, 1917. Date of appl., Sept. 15, 1916.

HOT air is supplied under pressure to a drying chamber through a series of ducts in one wall, and the moisture-laden air is discharged through a series of ducts in the opposite wall. The openings of the ducts in both walls face downwards.—W. H. C.

Treating [clinkering] materials; Process of —. F. W. Yost, Assignor to E. A. Bern, Chicago, Ill. U.S. Pat. 1,231,831, July 3, 1917. Date of appl., June 23, 1916. Renewed Oct. 10, 1912.

THE surface of a mass of finely-divided material, which is capable of being clinkered and which contains some combustible constituents, is heated during the whole time of treatment. A current of

furnace gas is introduced through the heated surface and passed through the mass of material in such a manner that the mass is clinkered.

—W. H. C.

Clarifier; Centrifugal —. L. G. Camp, Santa Clara, Cuba. U.S. Pat. 1,230,560, June 19, 1917. Date of appl., Feb. 8, 1913.

A DRUM open at the top and bottom is mounted on and rotated by a vertical shaft. The drum is provided with a bottom disc and a helix, which when the drum is rotated at a high speed, causes the deposited solids to move downwards along the inner wall of the drum and the liquid to move upwards and be discharged over the upper edge. The speed of rotation is kept constant by a control sleeve or brake fitted on the central shaft and regulated by the amount of solid matter accumulating at the inner surface of the drum.—W. H. C.

Centrifugal separating machine; Liquid —. F. A. Reece, Hopkinton, Mass. U.S. Pat. 1,230,601, June 19, 1917. Date of appl., Feb. 8, 1915.

A FLOAT device, controlled by the specific gravity of the outflowing liquid, is provided in one of the outlets of a centrifugal separator, so that the relative dimensions of the two outlets for the separated liquids, and consequently the relative specific gravities of the liquids, are regulated by the specific gravity of the liquid flowing past the float.—W. H. C.

Gas engines; Utilisation of the waste heat of —. C. Schindler, Wiesbaden, Germany. U.S. Pat. 1,231,208, June 26, 1917. Date of appl., Jan. 24, 1914.

THE cylinder and exhaust pipe of a gas engine are provided with separate connected water jackets, and the exhaust pipe jacket contains a helical rod to cause a corresponding circulation of the water. The water circulates in a closed cycle containing a pump, a throttling device which prevents vaporisation on one side and permits it on the other, and also a heat-utilising device.

—W. F. F.

Condenser for cooling aeriform fluids. H. E. Cole, Yokohama, Japan, Assignor to Standard Oil Co., Bayonne, N.J. U.S. Pat. 1,231,709, July 3, 1917. Date of appl., Apr. 3, 1911.

A NUMBER of groups of parallel condensing pipes are arranged in the same plane; transverse inlet and outlet headers are provided for each group, and each header is connected by a pipe, at right angles to the condenser pipes, to a pair of common supply and discharge headers which are parallel to the system of condensing pipes. The groups of condensing pipes are arranged in such a manner that the combined length of the pipes leading to and from the headers of each set of condensing pipes is the same for all the pairs of headers.

—W. F. F.

Kiln. M. R. Isaacs, Philadelphia. U.S. Pat. 1,231,893, July 3, 1917. Date of appl., July 7, 1916.

A HORIZONTAL drying chamber is provided with means for heating the air entering at one end, and with a vertical exhaust flue at the other end. The opening between the chamber and flue is regulated by a door sliding vertically, and attached by a flexible member passing over a pulley above the door, to the outer edge of a damper in the flue pivoted in the vertical wall containing the sliding door. The door and damper are thus connected so that when one opens the other closes. An exhaust fan is provided below the damper.—W. F. F.

Superheated steam; Method of and apparatus for regulating the temperature of —. D. S. Jacobus, Jersey City, N.J., Assignor to The Babcock and Wilcox Co., Bayonne, N.J. U.S. Pats. (A) 1,231,894 and (B) 1,231,895, July 3, 1917. Date of appl., June 11, 1915.

(A) SUPERHEATED steam is cooled by conduction in contact with a cooling medium to a predetermined constant temperature, which is maintained by varying the amount of cooling medium by the action of a thermostat operated by the cooled steam. The thermostat comprises a closed vessel containing a volatile liquid in which a variation of temperature produces a variation of vapour pressure which controls the means for regulating the flow of cooling medium. (B) In apparatus as in (A) the variation of vapour pressure in the thermostat operates means to close an electric circuit which operates an electric motor. A valve in the pipe conveying cooling medium to the steam pipe is operated by the motor so as to vary the flow of the cooling medium. The flow of superheated steam from the boiler is not restricted.

—W. F. F.

Distributors or conveyors for lime and like materials. T. W. S. Hutchins, Middlewich, Eng. Pat. 107,875, Sept. 18, 1916. (Appl. No. 13,227 of 1916.)

Dry products from liquids, emulsions, and the like; Process and apparatus for obtaining —, also adapted for producing chemical reactions. G. A. Krause, Munich, Germany. Eng. Pat. 107,417, June 27, 1916. (Appl. No. 9046 of 1916.)

SEE U.S. Pat. 1,213,887 of 1917: this J., 1917, 329.

Solid matter in finely divided form; Process and apparatus for obtaining — from liquids, solutions, emulsions, and the like, with or without chemical reaction. G. A. Krause, Munich, Germany. Eng. Pat. 107,418, June 27, 1916. (Appl. No. 9047 of 1916.)

SEE U.S. Pat. 1,213,659 of 1917: this J., 1917, 377.

[Water] still. U.S. Pat. 1,231,857. See XIXb.

Method and apparatus for distilling and evaporating [water]. U.S. Pat. 1,232,269. See XIXb.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Combustion in the fuel bed of hand-fired furnaces. H. Kreisinger, F. K. Ovitiz, and C. E. Augustine. U.S. Bureau of Mines, Techn. Paper 137, 1916. pp. 76.

THE research is in continuation of an investigation of combustion in boiler furnaces (Techn. Paper No. 63; this J., 1915, 17). Three kinds of fuel were employed in the tests, viz., Pittsburgh bituminous coal, anthracite, and coke. Most of the results were obtained in a furnace of special construction, but they were confirmed on typical hand- and mechanically-stoked boiler furnaces. The experimental furnace was in the form of a vertical cylinder having a grate area of 1 sq. ft., placed above an airtight ash-box. The air supply was driven under suitable pressure (8 in.—20 in. water) through an orifice, the pressure drop at which enabled the volume of the air to be measured. The furnace was open at the top and placed under a hood communicating with a chimney. Through holes in the wall of the furnace and at different levels, water-cooled gas-sampling tubes could be introduced or observations of temperature made with an optical pyrometer. Fuel was added from above, and from above also the fuel

bed could be maintained at a desired thickness and its surface kept level. The fuel consumption was varied from 20 to 185 lb. per sq. ft. of grate area per hour. During a test the thickness of the fuel bed was kept constant, either 6 in. or 12 in. Accumulation of ash or clinker was prevented by frequent shaking of the fire bars. The general conclusions arrived at were that the fuel bed in most furnaces acts primarily as a gas producer. With a 6 in. fuel bed all oxygen in the air supply is consumed in the first 4 in. from the grate. At 4 in. the CO₂ content of the gases has reached a maximum of 10—16% and above 4 in. it decreases, giving place to carbon monoxide. At the surface of the fuel bed, if the latter is free from "holes," no uncombined oxygen exists, but 20—32% of combustible gases. The composition of these gases is practically independent of the rate of air supply. If the latter is increased the fuel consumption rises proportionately, so that the ratio of air supply to fuel consumption remains constant at about 7 to 1. The weight of air theoretically required is about 15 times the weight of coal, so that at least half of the air must always be supplied above the fuel bed. The temperature of the bed is highest at a level of 3—5 inches above the grate, i.e., where the carbon dioxide content is greatest. The ash fuses in and above this region where high temperature and reducing conditions occur together. Further down, where the temperature is lower and the atmosphere oxidising, solidification to clinker occurs. These results show that in practice a thick fuel bed is not necessary for quick combustion and high rates of steaming. A fuel bed 6 in. in thickness is sufficient if free from holes and clinker. Indeed a deep bed actually reduces the rate of combustion by hindering the passage of air which, as has been shown, determines the rate of fuel consumption.—H. J. H.

Tar oil fuel and Diesel engines. G. Porter. Engineering, 104, 75—78, 103—107.

THE author gives details of four specifications for tar oil for Diesel engines, and results of tests on seven different samples of oil. It is desirable to keep the sulphur content and the suspended solids low. The calorific values agree very closely, and should not be less than 15,800. The author suggests that tar oil is better stored under cover at a moderately high temperature. It has been found that tar oil produces a higher temperature than a residual petroleum fuel oil, but this is not serious if allowance is made for the slower burning of tar oil by advancing the fuel admission. The author gives a series of calculations from indicator diagrams of engines using tar oil with and without pilot jet ignition. In general the diagrams with the pilot jet are not so nicely shaped as when using petroleum or tar oil without pilot jet ignition, the prior ignition producing a "peaked" admission line as compared with the regular, drooping curve which denotes combustion at constant pressure. The ideal quantity of ignition oil at full load is 5%. In the ordinary course of running the speed control by the governor is satisfactory when using tar oil, impulses are regular, and it is seldom that a cylinder "misses." In using tar oil one or two adjustments must be made. Earlier fuel admission is necessary, the amount of advance depending on the quality of the oil. As with residual petroleum oil, the colour of the exhaust is a guide to correct timing. In using tar oil alone it is necessary to reduce the injection pressure to ensure steady operation. The compression pressure in the cylinders at no load should not be less than 480 lb. per sq. in. It is considered very desirable to fit relief valves to the cylinders when using tar oil. With regard to the pulverisers, there is considerable trouble owing to the choking of the cone grooves and

rings, deposits collecting rapidly. The deposit may be due to insufficient pulverisation or may be due to the oil itself, possibly to naphthalene or incombustible matter. Figures taken from daily records appear to indicate that the tar oil and pilot jet engine is better than the petroleum oil engine not only in cost of working but in efficiency also. The author gives figures relating to fuel cost in power stations, showing a saving in fuel cost varying from 0.26d. to 0.49d. per kilowatt-hour due to the use of tar oil.—J. E. C.

Water-gas plants; operating carburetted — for the production of blue water-gas. Gas. J., 1917, 139, 61.

In notes compiled and issued by the Council of the Institution of Gas Engineers, it is stated that blue water-gas can be made in carburetted water-gas plants without any structural alteration by readjustment of generating conditions. As heat is not required in the carburetting chambers, the object to aim at is to minimise the waste of heat due to the volume of carbon monoxide and the quantity of sensible heat in the blast products by slow steaming and quick blowing; this may be effected by gradually altering the timing of the cycle. The best method is to adopt a somewhat shorter cycle with the fuel depth unaltered. Thus for a customary cycle of 3-minute "blows" and 5-minute "runs," one of 2-minute "blows" and 5-minute "runs" may be substituted, keeping the carbon dioxide in the finished blue gas below 6%. The coke used in the generator should be of suitable size, dry, and free from dust and breeze. The analysis of blue water-gas is approximately: H_2 50.5%, CO 38.5%, CO_2 6.0%, N_2 3.5%, CH_4 1.0%, and H_2S 0.5%, the calorific value being about 300 B.Th.U. gross. In mixing blue water-gas with coal gas it is necessary in many cases to increase the calorific value of the coal gas, which should be at least 540 B.Th.U. if the mixture is to contain 20% of blue water-gas.

Petroleum industry in Assam; Development of the —. H. S. M. Jack. J. Roy. Soc. Arts, 1917, 65, 589—596.

The petroleum industry in Assam is of purely modern development. At present the Assam Oil Co. is the only company producing oil, the two areas it works being known as the Makum and Digboi areas. The strata found on the fields consist of hard shales and clays of various sorts, including bands of a very soft, spongy nature and sandstone of all degrees of hardness. Various methods of drilling have been used, the one finding most favour being a Parker rotary plant. The ideal method for work in Assam would be to use a rotary system for the soft strata and a percussion system for the hard, but a satisfactory combination has not yet been found. Considerable gas pressures are found and not until a well has reached a mature age is pumping necessary. The pure crude oil has sp. gr. 0.856, is very dark brown, almost black in colour, and is perfectly fluid at 82° F., at which point crystals of paraffin separate. At 77° F. the oil loses fluidity and becomes semi-solid. The crude oil after settling is pumped into boiler stills arranged in groups of three. Distillation is continuous. From the first still crude benzine is taken off, from the second intermediate kerosene, and from the third the bulk of the ordinary kerosene. The residue is distilled to dryness in intermittent pot-stills, the whole of the middle distillate being passed through an anhydrous ammonia and a carbonic acid refrigerating machine in succession. From the former is obtained the bulk of the wax of high melting point, from the latter the basis of the batching oil, used for softening jute fibre. Non-condensable vapours are

burnt in the furnaces. The crude benzine is redistilled with closed steam, giving two qualities of petroleum spirit of sp. gr. 0.710 and 0.750 respectively. To stimulate sales, the company has developed a system of lighting, by converting the spirit into vapour which is burnt with an incandescence mantle. The intermediate kerosene is of great power value in internal combustion engines, whilst a small amount of water-white kerosene is produced for the use of Europeans. The batching oil is concentrated to sp. gr. 0.885 to 0.890. The paraffin wax is a hard wax of very high melting point, the standard adopted being 135° F.; the wax is marketed in a semi-refined state. The waste in distillation has been reduced to about 5% of the crude oil.—J. E. C.

Bituminous and tarry substances and hydrocarbon oils; Action of sulphur monochloride on —. J. V. Meigs. J. Ind. Eng. Chem., 1917, 9, 655—658.

SULPHUR monochloride reacts with bituminous matter, tarry substances, and hydrocarbon (gas-engine) oils, hydrochloric acid being evolved. With asphalts, the reaction was so quiet as to be scarcely noticeable, but with tar binder, heat was developed, vigorous ebullition and frothing occurred, and a black, friable powder, insoluble in carbon bisulphide, was produced. By using a 10% solution of sulphur monochloride in dry carbon bisulphide, the reaction proceeds quantitatively and the hydrogen chloride evolved may be aspirated through water and titrated with $N/20$ sodium hydroxide solution, using methyl orange as indicator. The reaction may be used as a test for the relative stabilities of transparent lubricating oils. The colour produced by the action of sulphur chloride on gas-engine oils is an indication of the degree to which they have been refined.

Asphalts; Relations of the effect of overheating to certain physical and chemical properties of —. A. W. Hixson and H. E. Hands. J. Ind. Eng. Chem., 1917, 9, 651—655.

CARBENES (hydrocarbons extracted from asphalts by carbon bisulphide) are probably formed by the cracking of asphaltic hydrocarbons. To investigate the conditions of their formation, 100 grms. each of crude Trinidad asphalt, a brick filler consisting of a natural asphalt fluxed with 70% of asphaltic oil residuum, and an oil-asphaltic cement of unknown origin were heated to various temperatures for 5 hrs. in a porcelain crucible, poured out, and allowed to cool. In each case after the material had been heated to 200° C. there was an increase in the fixed carbon and in the melting point, and decreases in the penetration and in the carbene content which were proportional to the temperature at which the material had been heated. After heating to 235° C., the melting points continued to rise, the Trinidad asphalt and filler became harder, but the oil cement remained soft; the Trinidad asphalt and oil cement became more viscous and the brick filler showed its maximum fluidity. After heating to 265° C., a break was observed in the graphs depicting the various properties: the melting points, fluidity, and fixed carbon of the Trinidad asphalt and the oil cement were lowered and the proportion of carbenes in all three materials was greatly increased. After heating to 300° C., the Trinidad asphalt became very hard and infusible. The brick filler became hard, but the oil cement was soft and mealy. The penetration of the Trinidad asphalt and filler became less, but that of the oil cement greatly increased, whilst its melting point was reduced. In each case, an increase in fixed carbon and carbenes and a loss of fluidity occurred. It appears probable that heating up to 200° C. merely distils off the lighter hydro-

carbons. On heating to 235°–265° C., the proportion of carbon to hydrogen is reduced, indicating that hydrocarbons rich in carbon and of low boiling point distil over. The nature of the residue requires investigation. Upon heating to 300° C., the proportion of carbon to hydrogen is increased owing to cracking and the formation of carbonaceous consisting of either unsaturated hydrocarbons or naphthenes. It is suggested that the fixed carbon graph (corrected by multiplying the fixed carbon by the percentage of residue left on heating and dividing by 100) offers a means of tracing the changes in the molecular structure of the hydrocarbons when heated. There is a close relation between the proportion of carbon and the physical properties of asphaltic materials.—A.B.S.

Effusion method of determining gas density. Edwards. See XXIII.

Specific gravity balance for gases. Edwards. See XXIII.

PATENTS.

Fuel; Apparatus for feeding powdered or pulverised —. F. Caldwell, Cincinnati, Ohio. U.S. Pat. 1,231,488, June 26, 1917. Date of appl., Sept. 26, 1916.

POWDERED fuel contained in the hopper, 10, is fed by the screw conveyor, 17, to the tapered outlet, 33, and thence through an opening in the inclined portion, 31, of the pipe, 24, through which

air is supplied for combustion. An inclined diaphragm in the pipe diverts the fuel into the current of air, with which it is mixed in the helical portion of the pipe, and finally discharged by the nozzle, 25, into the furnace, 29. Steam is passed through the chamber, 23, to heat the air, and through the jacket, 14, to dry the fuel.—W. F. F.

Water-gas producers; Apparatus for equalising the pressures in the producer and in the space below the grate of water-sealed —. B. Spitzer, Berlin-Wilmersdorf. Ger. Pat. 298,387, Feb. 13, 1915.

THE apparatus consists of a double valve containing two pistons of different diameter, on the same rod, supported by a counterweight over a pulley. Each piston runs in a cylinder, the larger being below. The pressure in the producer operates on the lower and that in the ash space on the upper side of the bottom piston. An increased pressure on the lower side of the latter, i.e., in the producer, causes it to rise and therefore lifts the upper piston, which opens air ports allowing an increased blast pressure to operate in the ash chamber. A fall in the producer pressure acts oppositely, and thus the apparatus prevents the development of pressure differences between the producer and the ash space.—H. J. H.

Water-gas; Continuous production of —. A. F. Holmgren, J. V. Aqvist, and G. Helsing, Trollhättan. Ger. Pat. 298,119, Jan. 16, 1915. Under Int. Conv., Nov. 18, 1911.

STEAM, unmixed with air, is passed downwards through an incandescent bed of carbonaceous material. The producer consists of a vertical shaft, with feeding hopper and steam inlet at the top, and a grate at the bottom. The water-gas formed passes out through an opening in the side just above the grate. Above this outlet, two horizontal electrodes are introduced into the producer at opposite sides so that the temperature of the charge can be maintained electrically. The necessity for interrupting the making of gas by the "air-blow" period, and hence the attendant loss of fuel as carbon dioxide, are thereby obviated; the gas is also free from nitrogen. Wet peat, sawdust, or bituminous fuel may be gasified in place of coke.—H. J. H.

Coal gas; Preparation of — for storage in iron vessels under pressure, for incandescence lighting. J. Pintsch A. G., Berlin. Ger. Pat. 298,223, Dec. 5, 1915.

IF coal gas is stored under pressure in iron vessels, iron carbonyls may be formed, and these render it unsuitable for use with incandescence mantles. To avoid this, the gas is freed from carbon monoxide prior to compression.—H. J. H.

Petroleum; Apparatus for refining —. A. F. I. Bell, San Francisco, Cal. U.S. Pat. 1,231,695, July 3, 1917. Date of appl., May 10, 1916.

A SLIGHTLY inclined rotating cylindrical still is mounted on a hollow fixed central shaft. This shaft serves to supply the oil and also to carry off the vapours. A scraper attached to the hollow shaft removes carbon deposit from the inner surface of the still, and a scoop pipe, also carried by the shaft, collects the carbon and transfers it to the shaft, from which it passes to a collecting chamber formed by an enlargement of the shaft outside the still.—W. F. F.

Petroleum and other hydrocarbons; Method for treating [distilling] —. C. P. Dubbs, Wilmette, Ill. U.S. Pat. 1,231,599, June 26, 1917. Date of appl., Nov. 27, 1916.

To produce hydrocarbons of lower boiling point, petroleum is passed through a series of receptacles where it is subjected to progressively increasing temperatures and pressures. The temperature varies from a minimum of 200°–500° F. (93°–260° C.) to a maximum of 500°–2000° F. (260°–1090° C.), and the pressure varies from a minimum of 50 lb. per sq. in. to a maximum of 1000 lb. per sq. in. The vapour from the vessel at lowest temperature is collected and condensed, and the vapour from the other vessels is passed through reflux condensers, the condensate being returned to its own vessel and the residual vapour being passed through the vessel of next lower temperature in the opposite direction to the flow of petroleum.—W. F. F.

Gasolene substitute. T. E. Rice, Des Moines, Iowa. U.S. Pat. 1,230,924, June 26, 1917. Date of appl., May 13, 1916.

A LIQUID fuel suitable for use in internal combustion engines is composed of kerosene 1 gallon, methyl ether 4 oz., carbon bisulphide, 8 oz. —W. F. F.

Oil; Process of decomposing [cracking] —. A. A. Wells, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,232,454, July 3, 1917. Date of appl., Mar. 31, 1913.

THE vapour of heavy petroleum oil of predetermined gravity is cracked by passing it through a heated tube provided with metal baffling prongs

which produce a greater baffling effect at the centre than at the sides. The vapour is maintained at a pressure directly proportional to its density, and the condensable vapour is condensed and removed.—W. F. F.

[Asphaltic] material; Process of producing a plastic —. C. Baskerville, New York. U.S. Pat. 1,231,985, July 3, 1917. Date of appl., Nov. 13, 1914.

ACID sludge obtained as a by-product in the refining of petroleum oil by means of sulphuric acid is heated sufficiently to separate part of the contained oil but not sufficiently to carbonise the sludge. The separated asphaltic portion is removed and neutralised with slaked lime.—W. F. F.

By-product ovens, furnaces, and the like; Ascension pipes or flues of —. W. H. Proctor, Bankfoot Crook, Durham. Eng. Pat. 107,536, Jan. 16, 1917. (Appl. No. 805 of 1917.)

III.—TAR AND TAR PRODUCTS.

Phenols; Spectroscopic identification of —. J. Formánek and J. Knop. Z. anal. Chem., 1917, 56, 273—298.

A CRITICAL review and reinvestigation of the results of Gisell (this J., 1916, 35, 1054) on the identification of phenols by the absorption spectra of their phthalein condensation products. Apart from the fact that some of the phthaleins examined by Gisell cannot have been pure, it is not sufficient merely to indicate the position of the head of an absorption band, but the form should be represented graphically for varying concentration; also, where possible, the examination should be made in several different solvents. The method for effecting the condensation is to heat at 100°—180° C. about 0.1 gm. of the phenol with about one-half the weight of phthalic anhydride and 0.1 gm. of zinc chloride or 2—3 drops of sulphuric acid as condensation agent. When zinc chloride or tin chloride is used the colour may be affected by the formation of a lake on subsequent addition of alkali, whilst a complication of the phenomena is also possible with sulphuric acid, the use of which may in some cases give rise to sulphonation. Alternative methods of spectroscopic identification for phenols are possible by the use of a larger proportion of phthalic anhydride and of sulphuric acid at 160°—200° C., when an anthraquinone derivative may be obtained, and by warming with alcoholic or aqueous

sodium hydroxide and chloroform, with formation of a xanthene derivative. The following phenols were converted into their phthaleins and the spectra examined in aqueous and alcoholic solution; the results are tabulated and also graphically represented:—Phenol, *o*- and *m*-cresol, thymol, guaiacol, quinol, hydroxyquinol, Carvacrol, α -naphthol, catechol, resorcinol, α -naphthoresorcinol, orcinol, and phloroglucinol were converted into phthaleins and also into xanthene derivatives, and pyrogallol into phthalein and anthraquinone derivatives. A xanthene was obtained from β -naphthol, but no satisfactory phthalein; *o*- and *p*-hydroxybenzoic acids gave phthaleins identical with phenolphthalein, whilst with *m*-hydroxybenzoic acid phthalein formation was uncertain.—D. F. T.

Tar oil fuel and Diesel engines. Porter. See IIA.

Action of sulphur monochloride on bituminous and tarry substances and hydrocarbon oils. Meigs. See IIA.

PATENTS.

Tar; Continuous distillation of —. B. E. D. Kilburn, London. From Sulzer Frères, Winterthur, Switzerland. Eng. Pat. 107,168, Jan. 2, 1917. (Appl. No. 77 of 1917.)

THE apparatus consists of two drums set horizontally at different levels in the furnace brickwork. The tar is fed continuously into the upper drum through a preheating coil arranged above the latter. The ammonia and light oil are distilled off in this drum and conveyed to a condenser. The hot tar then passes to the lower drum where the distillation is completed. The vapours pass to a separate condenser, and the pitch flows away continuously from the hottest part of the drum. The lower drum is heated by a furnace placed below, and the hot gases, after circulating round the lower drum, pass round the upper drum. A by-pass flue is provided so that all or any desired proportion of the products of combustion can be conducted directly to the upper drum.—W. H. C.

Aromatic hydrocarbons; Process of making —. C. M. Alexander, Port Arthur, Tex., Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,230,975, June 26, 1917. Date of appl., Nov. 10, 1915.

BENZENE and toluene are obtained by passing vapours of hydrocarbons of high boiling point, e.g., solvent naphtha, through a heated zone at about 600°—1000° C., at a rate sufficiently rapid to give a condensate having about 70% of the volume of the original hydrocarbon and containing high-boiling oils. The vapours are condensed and the benzene and toluene separated. The solvent naphtha may be mixed with once-treated high-boiling oil.—F. W. A.

IV.—COLOURING MATTERS AND DYES.

Cochineal; Detection of ammoniacal —. C. F. Muttelet. Ann. Falsif., 1917, 10, 228—230.

AMMONIACAL cochineal gives an amethyst colour whereas cochineal carmine gives an emerald green colour on addition of aqueous uranium acetate solution to a neutral amyl alcohol solution of the colouring matter. The carmine may be separated from a mixture of the two colouring matters by treating the amyl alcohol solution with calcium carbonate to form its insoluble lake; the ammoniacal cochineal is extracted from the lake by cold water and identified as such or after conversion into the carmine by boiling with caustic alkali.—F. W. A.

Nitrosopyrrole Black. A. Angeli and G. Cusmano. Atti R. Acad. Lincei, 1917, [v.], 26, i., 273—278. J. Chem. Soc., 1917, 112, i., 413.

WHEN an aqueous solution of the sodium salt of isonitrosopyrrole is treated with carbon dioxide, or when pyrrole reacts with ethyl nitrite or nitrous acid, a black powder, named Nitrosopyrrole Black, is obtained. This product is almost insoluble in most solvents, but dissolves easily in alkali and is reprecipitated by acid; in alkaline solution it is instantly oxidised by permanganate and is decolorised by reducing agents, the dark colour subsequently reappearing in the air. The composition agrees approximately with the formula $(C_4H_5ON_2)_n$. Nitrosopyrrole Black does not melt, but at a high temperature deflagrates with liberation of red vapours. This compound appears to be accompanied by another, also black, which has not yet been investigated. In Nitrosopyrrole Black the CO-group of Pyrrole Black (this J., 1917, 210) is replaced by NO: $(C_4N)CO \rightarrow (C_4N)NO$.

PATENT.

Dyes or stains; Production of — [from bananas or plantains]. W. W. Coe and W. W. Coe, jun., London. Eng. Pat. 107,094, July 11, 1916 (Appl. No. 9775 of 1916) and Jan. 31, 1917 (Appl. No. 1584 of 1917).

THE pulp and/or skin of the banana or plantain is treated with an alkaline solution or a mineral acid, in presence or absence of a metallic compound, with subsequent neutralisation or partial neutralisation. The resulting dyes or stains may be used for dyeing with or without mordants.—F. W. A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wood gum in incompletely purified cotton; Determination of —. M. Freiburger. Z. anal. Chem., 1917, 56, 299—308.

THE author suggests a method for the examination and estimation of the organic constituents of cotton other than pure cotton cellulose and fat. The material is extracted with a cold 5% aqueous solution of sodium hydroxide for 24 hours, the dissolved matter being subsequently precipitated in fractions by successive addition of alcohol, neutralisation with hydrochloric acid, and acidification with hydrochloric acid, a period of 48 hours being allowed at each stage of the treatment for the completion of the precipitation. The first deposit consists largely of cellulosic material and he second of xylan with cellulosic substances, whilst the third also contains fatty acids. In each case the precipitated material contains sodium chloride for which a correction is made. After his treatment with cold alkali the cotton still contains a small quantity of oxycellulose, wood gum, and fatty material. This is removed by a further extraction for 5 hours at 100° C. in an apparatus from which air is excluded, with a 1% sodium hydroxide solution to which have been added a little resin and dextrose, the residual cellulose being well washed, dried, and weighed. Under these conditions approximately only 1% of the cellulose proper is dissolved and, in calculating the total weight of "wood gum," a corresponding correction is made for this loss and for the extracted it. A small quantity of "wood gum" persists in solution during the various operations in the first stage of the treatment and so is not included in the result.—D. F. T.

Paper; Physical testing of — as affected by humidity. R. Campbell. J. Ind. Eng. Chem., 1917, 9, 658—661.

WITH an increase of 50—98% in the relative

humidity, the shrinkage of paper increased 40—50%; longitudinal stretching increased 30%, and cross stretching 40—50%. Folding tests gave maximum results at 80% relative humidity. The time required for ink penetration decreased 40—50% as the relative humidity increased from 55—100% at 80° F. The effect of a good tub size on the physical properties of paper is very advantageous.—A. B. S.

PATENTS.

Paper; Process of making fibre for —. V. Drewsen, Brooklyn, N.Y. U.S. Pat. 1,229,422, June 12, 1917. Date of appl., Mar. 12, 1915. Renewed Feb. 27, 1917.

CORNSTALKS are boiled for 5—6 hours under a pressure of 40—120 lb. (preferably 60—70 lb.) per sq. in., in the absence of substantial proportions of free caustic alkali or strong acid, with a liquid containing sufficient sodium sulphite to represent about 25% of the dry weight of the raw material and remain alkaline to litmus during the entire digestion process.—J. F. B.

Paper [coated]. J. E. Baum, jun., Chicago, Ill. U.S. Pat. 1,230,095, June 19, 1917. Date of appl., Feb. 11, 1916.

THE paper, in sheet or web, has a coating of uncombined silica, in a state of impalpable powder, mixed with clay or a colouring matter and sufficient size to act as a binder and form a very smooth surface after calendering.—J. F. B.

Sizing paper, cardboard, and the like; Method of —. A. H. Haeflner, Skutskär, Sweden. U.S. Pat. 1,231,153, June 26, 1917. Date of appl., Jan. 15, 1917.

SIZING material is precipitated from fermented sulphite liquor by means of alum, aluminium sulphate or the like, before or after incorporation of the liquor with the pulp.—F. W. A.

Sized sheets; Apparatus for waterproofing —. S. Elliott, Newton, Mass. U.S. Pat. 1,230,068, June 12, 1917. Date of appl., Dec. 28, 1914.

THE apparatus comprises a closed chamber in which the sized sheets are suspended, containing a small vessel fed by means outside the chamber with a determined quantity of a volatile liquid, such as formaldehyde, which on heating gives off a vapour; a blower is provided inside the chamber which causes a mild circulation of air through restricted openings arranged on opposite sides of the chamber.—J. F. B.

Fibres; Treatment of — to increase their coefficient of friction on each other. W. E. Muntz, London. U.S. Pat. 1,232,374, July 3, 1917. Date of appl., Apr. 4, 1914.

SEE Eng. Pat. 8278 of 1913; this J., 1914, 546.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Cotton fibres; Chemical and physical changes in — with special reference to the processes of dyeing. R. Haller. Kolloid Zeits., 1917, 20, 127—145. J. Chem. Soc., 1917, 112, i., 436.

THE chemical and physical properties of cotton fibres lead to the conclusion that the outer membrane consists of two structural elements which show but small differences under normal conditions. When the cellulose is transformed into hydrocellulose and oxycellulose, the two components are much more readily differentiated. The difference is shown in the behaviour towards chemical reagents and in the appearance under

the ultra-microscope. The proof that two such structural elements are involved is considered to afford evidence in support of Nägeli's micellar theory of the structure of vegetable membranes. The absorption of mordants and dyes by the penetration of these substances into the micellar interstices is dependent on the degree of dispersion of the particles. The power of penetration is limited to particles of diameter less than about 5μ . In the case of mercerised fibres, the micellae are more widely separated than in the original untreated fibres, and particles of larger size than those above referred to may accordingly be absorbed, with the result that the depth of colour is greater.

PATENTS.

Printers' blankets; Fabric for — and other purposes. F. E. Ellis, Revere, Mass. U.S. Pat. 1,231,141, June 26, 1917. Date of appl., Mar. 21, 1917.

A BLANKET for printing presses consists of a body layer of relatively expensive material with a face ply of textile fabric secured by an adhesive, waterproof, and oil-proof cement, and a non-offsetting film of a smooth, non-porous, ink-repellent coating (e.g., nitrocellulose with sufficient emollient to render it flexible and non-brittle) attached to the outer side of the face layer.—F. W. A.

Weighting of silk filaments and fabrics in the form of hanks; Apparatus for the —. P. Schmid, Basle, Switzerland. U.S. Pat. 1,231,136, June 26, 1917. Date of appl., Sept. 20, 1916.

AN apparatus for weighting silk filaments and fabrics consists of a vat containing in its upper part a row of horizontal hank supports arranged so that they can be tilted, and provided with spraying tubes arranged above the hank supports in such a manner that all may be turned back together, and other tubes underneath the hank supports, with each tube connected to the corresponding hank support so that it can be turned back with it.—F. W. A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Brines; Chemical examination of natural —. O. R. Sweeney and J. R. Withrow. J. Ind. Eng. Chem., 1917, 9, 671—674.

THE following determinations are recommended:—*Deposit on aeration.*—The sample is allowed to stand, with occasional shaking, for two or three days to aerate any iron compounds present. The height of the liquid in the bottle is marked and the whole is filtered and the deposited matter is washed (the washings being kept separate), dried, and ignited to constant weight. The volume of the sample is measured by ascertaining the capacity of the original container. The *specific gravity* of the filtered brine at 15°C . is determined by the Westphal balance. The sp. gr. of the fresh brine is different from that of the sample after several days. *Total solids* are determined on 25 c.c. of the filtered sample; the residue is dried at 160°C . *Silica* is separated in the usual manner, and the residue is treated with sulphuric and hydrofluoric acids and the loss of weight reported as silica. The residue is added to the iron and alumina precipitate. *Iron and alumina* are estimated by precipitating with ammonia from the filtrate and washings from the silica. A separation of the iron and alumina is seldom required. *Calcium.*—The filtrate from the iron and alumina is diluted, and the calcium precipitated as oxalate and ignited to oxide. Its

amount is checked by dissolving it in dilute sulphuric acid and titrating with potassium permanganate. The calcium should be reported as sulphate and chloride. *Magnesium.*—The combined filtrates and washings from the calcium are acidified with hydrochloric acid, and the magnesium precipitated with sodium hydrogen phosphate, ignited to $\text{Mg}_2\text{P}_2\text{O}_7$, weighed, and calculated to bromide and chloride. *Barium and strontium* should be looked for in the absence of sulphates. They are partially precipitated with the calcium and magnesium. When the proportion of barium and strontium is low, they may be neglected. *Ammonia* is seldom present in commercially important proportions. *Sulphuric acid.*—The barium sulphate precipitate is filtered, washed, and ignited in a porcelain crucible. It is then dissolved in a few c.c. of warm concentrated sulphuric acid and poured into 250 c.c. water, allowed to stand and then filtered, washed, ignited, and weighed. (This method of purifying the barium sulphate is very effective.) The sulphuric acid is reported as calcium sulphate. *Potassium and sodium.*—The filtrate from barium sulphate is used for determining the potassium and sodium, by the method described in "Mineral Waters in the U.S.A.," Department of Agriculture Bulletin 91. They are reported as potassium and sodium chlorides. *Chlorine* is estimated by titration with silver nitrate solution. The bromine value must be deducted. *Bromine* is liberated by treatment with chlorine and its amount determined colorimetrically. The bromine should be reported as magnesium bromide as it is so considered by the trade, but any free bromine should be reported as such. —A. B. S.

Bromides; Valuation of —. E. Rupp and E. Hollatz. Arch. Pharm., 1917, 255, 120—129. J. Chem. Soc., 1917, 112, ii, 327—328.

THE authors have developed a volumetric method for the estimation of bromides in the presence of small quantities of chlorides, which is designed especially for the valuation of pharmaceutical preparations, such as *Bromum compositum*, D.A.-B. ($\text{KBr}:\text{NaBr}:\text{NH}_4\text{Br}$, 2:2:1). The process is summarised in the following equations: $5\text{KBr} + \text{KBrO}_3 + 6\text{H}_2\text{SO}_4 = 3\text{Br}_2 + 6\text{KH}_2\text{SO}_4 + 3\text{H}_2\text{O}$; $\text{Br}_2 + 2\text{NaOH} + \text{H}_2\text{O}_2 = 2\text{NaBr} + \text{O}_2 + 2\text{H}_2\text{O}$; $\text{KBrO}_3 + 6\text{KI} + 6\text{H}_2\text{SO}_4 = 3\text{I}_2 + 6\text{KH}_2\text{SO}_4 + \text{KBr} + 3\text{H}_2\text{O}$. The reason for removing the bromine by the application of alkaline hydrogen peroxide, rather than by boiling, is that the excess of bromate is not stable in hot acid solutions. Ammonium salts tend to produce bromates at this stage, however, so the first step is really to expel any ammonia by boiling with sodium hydroxide. The solution is then cooled, acidified, treated with a definite excess of bromate, then mixed with alkaline hydrogen peroxide, and, after boiling, acidifying, and adding potassium iodide, the iodine is titrated by thiosulphate. Sufficiently trustworthy results are obtained even if the mixture contains as much as 25% of a chloride.

Perchloric ion; Micro-chemical reactions of the —. G. Denigès. Ann. Chim. Analyt., 1917, 22, 127.

THE reactions between perchloric acid and alkaloids, notably strychnine, brucine, and morphine (this J., 1917, 616), may be used conversely for the detection of the perchloric ion. A small drop of the solution of perchloric acid or a soluble perchlorate is stirred with the point of a drawn-out glass rod which has previously been dipped in a 2% solution of brucine in 0.01% acetic acid, or a 2% aqueous solution of morphine hydrochloride or of strychnine sulphate. Should a turbidity appear, either immediately or after further stirring, the drop is examined under the micro-

scope. Strychnine sulphate is capable of detecting 0.01 mgrm. of the perchloric ion (1 grm. per litre), whilst brucine acetate will detect the perchloric ion in a solution containing 2 to 3 grms., and morphine hydrochloride in a solution containing 5 grms. per litre.—C. A. M.

Alkali chromates and bichromates; Chemical evaluation of —. J. P. Sacher. *Farbenzeit.*, 1916, 22, 213. *J. Chem. Soc.*, 1917, 112, ii., 337.

THE following method is sufficiently accurate for technical purposes and permits the estimation of chromate in presence of bichromate. Potassium bichromate can be titrated with potassium hydroxide in the presence of phenolphthalein in accordance with the equation: $K_2Cr_2O_7 + 2KOH = 2K_2CrO_4 + H_2O$. The titration can be performed without the indicator, since, at the neutral point, the colour of the solution changes from reddish-yellow to greenish-yellow. Potassium chromate can be estimated by titration with sulphuric acid according to the scheme: $2K_2CrO_4 + H_2SO_4 = K_2Cr_2O_7 + K_2SO_4 + H_2O$; Congo-red can be used as indicator.

Arsenic trisulphide. E. Schmidt. *Arch. Pharm.*, 1917, 255, 45—64. *J. Chem. Soc.*, 1917, 112, ii., 331—332.

PRECIPITATED arsenious sulphide is appreciably decomposed by water and even by alcohol, with formation of hydrogen sulphide. It is also attacked to a very considerable extent by dilute hydrochloric acid, but the action with dilute acid or with water is checked by the addition of a small quantity of hydrogen sulphide. The estimation of arsenic by precipitation and weighing as trisulphide (Püller. *Chem. Soc. Trans.*, 1871, 24, 971; Friedheim and Michaelis, this J., 1896, 135) gives results which are very slightly high, but actually the precipitate diverges more widely from the composition As_2S_3 than the errors would indicate, containing to some extent both arsenic hydrosulphide, $As(SH)_3$, and arsenious oxide, the respective errors being in opposite directions and tending to neutralise each other. A slightly modified method is suggested for the treatment of precipitated arsenic sulphide in order to convert it into an arsenious solution suitable for titration with iodine.

[*Action of hydrochloric acid on alumina, thorina, and zirconia.*] *Velocity of reaction in heterogeneous systems and size of granules.* E. Podszus. *Z. physik. Chem.*, 1917, 92, 227—237. *J. Chem. Soc.*, 1917, 112, ii., 300.

CERTAIN oxides, which in ordinary circumstances are unacted on by hydrochloric acid, are dissolved by this reagent to a very appreciable extent when the oxides are reduced to a fine state of subdivision. Experiments were made with aluminium oxide, thorium oxide, and zirconium oxide, and in each case the oxide was dissolved when the diameter of the particles was of the order $1\ \mu$. The results recorded show the progress of the dissolution when the concentration of the acid and the temperature were kept constant, and, further, the influence of variation in the acid concentration.

Sulphuric acid; Method of concentrating —. J. V. Skoglund. Brooklyn, N.Y. U.S. Pat. 1,232,109, July 3, 1917. Date of appl. May 4, 1916.

SULPHURIC acid is concentrated by passing hot gases through a spray of the acid. The method is continuous, the weak acid being passed into one end of a container fitted with an arrangement for producing the spray by means of a suitable gas under pressure, and the strong acid drawn off from the other end of the container. The greater part of the spray falls back into the container, any acid which is carried over by the stream of hot gases being removed by passing these through a mass of acid-proof material.—B. V. S.

Acetic acid; Process of making —. H. Hilbert. Pittsburgh, Pa., Assignor to Union Carbide Co., New York. U.S. Pat. 1,230,899, June 26, 1917. Date of appl. Aug. 15, 1916.

ACETIC acid is produced by the action of oxygen on acetaldehyde in the presence of wood charcoal previously saturated with the strong acid.—B. V. S.

Potassium chloride; Process for obtaining — from certain waters containing borax. N. Winkle, Keeler, and W. W. Watterson, Bishop, Cal. U.S. Pat. 1,232,156, July 3, 1917. Date of appl. Dec. 11, 1916.

A SOLUTION of potassium chloride, containing also sodium borate, sulphate, carbonate, and chloride, is largely freed from carbonate by treatment with carbon dioxide and concentration to the saturation point of potassium chloride at ordinary temperatures. The clear liquor is again treated with carbon dioxide with formation of bicarbonate, cooled for the separation of part of the borate along with the bicarbonate, and further concentrated and again cooled to crystallise potassium chloride and borax. The mother liquor is returned to more fresh liquor for further treatment and the mixed crystals dissolved, treated with chlorine or an acid to convert the borax into chloride and boric acid, and again crystallised. Boric acid is removed from the resulting mass by treatment with alcohol, and sodium chloride by washing with cold water.—B. V. S.

Magnesium compounds from silicate material; Process of making —. S. Peacock, Philadelphia, Pa., Assignor to Mardon, Outh and Hastings Co., Inc., New York. U.S. Pat. 1,231,423, June 26, 1917. Date of appl. Aug. 7, 1916.

A SILICATE containing magnesium is digested with an alkali hydroxide, with the formation of an alkali silicate and magnesium hydroxide, which are separated by any suitable means.—B. V. S.

Magnesium chloride; Manufacture of anhydrous —. E. A. Ashcroft, London. U.S. Pat. 1,231,741, June 26, 1917. Date of appl. Dec. 5, 1916.

A MAGNESIUM oxy-compound "in a fused medium" is treated with chlorine in the presence of a substance which promotes exothermic reaction.—B. V. S.

Chlorides; Manufacture of anhydrous metal——. E. A. Ashcroft, London. U.S. Pat. 1,232,169. July 3, 1917. Date of appl. Dec. 5, 1916.

METAL oxy-compounds are heated "in a fused medium" with chlorine in the presence of a chlorine carrier, which is then removed by evaporation and used for a further charge. Alternatively, the metal compound may be mixed with carbon and treated with chlorine in a fused medium, dry air being subsequently passed through the mass. —B. V. S.

Oxalates; Manufacture of——. F. A. Dugan, Brooklyn, N.Y. U.S. Pat. 1,232,249, July 3, 1917. Date of appl. Sept. 27, 1916.

SODIUM or other oxalate is prepared by spraying the metal into a pebble mill in which a heated atmosphere of carbon dioxide is maintained. —B. V. S.

Thorium; Process of separating from soda solutions containing thorium oxalate. I. Kreidl, Vienna. U.S. Pat. 1,232,334, July 3, 1917. Date of appl. Apr. 18, 1916.

BY heating a very dilute solution of sodium carbonate containing a thorium salt, the thorium compound is precipitated.—B. V. S.

Furnace; Electric——for fixing nitrogen from the air. S. Garford, Oakland, Cal. U.S. Pat. 1,232,179, July 3, 1917. Date of appl. Jan. 19, 1916.

AN electric arc is produced between two electrodes, and a current of air or gas is delivered by suitable means through the sphere of action of the arc. The gas, when it leaves the arc, passes through a cup-shaped, water-jacketed, annular discharge passage, acting as cooler, and having a large area in comparison with its volume so as to cool the gas rapidly. Means are provided for rotating one or both electrodes, and simultaneously feeding them into the furnace as they are consumed in the arc, in order to maintain a uniform heating and reaction.—B. N.

Phosgene; Method of manufacturing——. N. L. G. Whitehouse, Pittsburgh, Pa. U.S. Pat. 1,231,226, June 26, 1917. Date of appl. July 26, 1916.

CARBON monoxide is bubbled through liquid chlorine maintained at a temperature below -34°C .—B. V. S.

IX.—BUILDING MATERIALS.

Portland cement; Preliminary report on blended——. E. S. McCandless. Bulletin, Feb., 1917, School of Mines and Metallurgy, University of Missouri.

PARTICLES of Portland cement which will not pass a standard No. 200 screen are stated to have no cementing properties. According to the standard specifications for fineness, 22% by weight may be retained by such a screen, and this amount is practically inert as a cement. General experience of cement shows that the economic limit of fineness of grinding of the clinker has apparently been reached, and the suggestion has been made that some cheaper material of suitable sized grain might be substituted for the coarser, inert particles of clinker; such a mixture is termed a "blended cement." Experiments were made with three commercial Portland cements, and mixtures were made of (1) the portion of each cement that easily passed a No. 200 sieve, and (2) quartz sand, all of which passed a No. 65 sieve, and of which about 17% passed a No. 200 sieve. Mixtures were made with 10, 20, 30, and 40 parts by weight of sand in 100 parts of the blended cements. The physical tests made were, tension, neat and mortar, compression, neat and mortar, normal consistency, time of setting, constancy of volume (normal and accelerated tests), fineness and sieve analysis, and specific gravity. It appears that the tensile strength of both neat cement and cement mortar develops at approximately the same rate in both Portland cement and blended cements, and the former is not superior to the latter. In the case of the neat cement tests, the 10 and 20% blended cements were slightly inferior, but the 30 and 40% blended cements were equal to Portland cement. When the blending material did not exceed 30%, the blended cement mortar was superior to Portland cement mortar. The results obtained with neat cement under compression lacked uniformity, but when the blended material did not exceed 30%, the compressive strength of the blended compared favourably with that of Portland cement. In the case of mortar, the compressive strength varied inversely with the amount of blending material used, and was less than that of Portland cement mortar. The normal consistency of Portland cements varies within narrow limits and that of blended cements varies inversely with the amounts of blending material used. The initial and final setting of cements with more than 20% of blended material takes place more slowly than that of the cements from which they are derived, but up to 40% of blended material they may still satisfy the standard specifications. Cements with less than 40% of blended material satisfy the specification for soundness, and those containing 30% approximate most nearly to Portland cement in fineness and gradation of size of particles. In brief, Portland cements which pass a No. 200 sieve may be blended with 40% by weight of quartz sand which passes a No. 65 sieve and leaves a residue of 20% on a No. 200 sieve, and still pass the standard specifications. Quartz sand is a satisfactory substitute for the inert clinker particles in Portland cement and maintains the present physical characteristics of it when added in amounts not exceeding 30% by weight.—W. C. H.

Cement-mill polish; The nature of——. R. J. Nestell and E. Anderson. J. Ind. Eng. Chem., 1917, 9, 646—651 (see also this J., 1917, 458).

THE dust in the chimney gases from cement kilns contains, *inter alia*, considerable quantities (averaging over 10%) of potash in both a readily and a slowly soluble form, i.e., partly as sulphate

and carbonate and partly as silicate. The presence of lime or of moist soil increases the rate of solution of the slowly soluble form. Hence, this dust should be valuable as a fertiliser.—A. B. S.

PATENTS.

Blocks; Method of treating porous ——. C. E. Fuller, Kansas City, Mo. U.S. Pat. 1,231,007, June 26, 1917. Date of appl., July 13, 1916.

THE method consists in heating a porous block, compressing the air in the pores, and forcing liquid asphalt into the pores at a pressure greater than that of the air, then reducing the pressure to atmospheric and suddenly cooling the block.

—W. C. H.

Artificial wood composition. L. S. Gibson, Jamestown, N.Y. U.S. Pat. 1,231,519, June 26, 1917. Date of appl., June 10, 1916.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Zinc from cadmium; A method of separating—and determination of the latter iodometrically. E. J. Eriksen. J. Ind. Chem. Eng., 1917, 9, 671.

FIVE grms. of ore is dissolved in nitric or hydrochloric acid, according to the nature of the ore, evaporated with 20 c.c. of sulphuric acid, water added, and the liquid boiled and filtered. To the filtrate a slight excess of ammonia is added, and the liquid boiled and diluted to 500 c.c., filtered, and an aliquot portion, representing 3 or 4 grms., is pipetted off and evaporated to small bulk and until a slight white precipitate appears; sulphuric acid is then added and the liquid evaporated to 80–100 c.c., and zinc sulphate allowed to crystallise out. The solution is then decanted and the crystals washed thrice with cold water. The filtrate is diluted to 200 c.c. and hydrogen sulphide passed until all the cadmium is precipitated. The precipitate is allowed to settle for several hours and is then filtered, dissolved in hot hydrochloric acid, neutralised with ammonia, and 10 grms. of trichloroacetic acid added; the liquid is diluted to 200 c.c. and reprecipitated with hydrogen sulphide. The pure cadmium sulphide may be determined by any recognised method, the gravimetric being the most accurate. An iodometric method of determining cadmium consists in mixing the separated sulphide with about 125 c.c. of water, adding a measured excess of N/10 iodine solution, and then 30–50 c.c. of dilute hydrochloric acid. The liquid is shaken and titrated with sodium thiosulphate, using starch as the final indicator: 1 c.c. of N/10 iodine solution = 0.00562 gm. Cd.—A. B. S.

Phosphor-tin and a volumetric method for its analysis. R. E. Lee, W. H. Fegeley, and F. H. Reichel. J. Ind. Eng. Chem., 1917, 9, 663–668.

PHOSPHOR-TIN alloys contain 0.1–6% phosphorus. They are insoluble in 5N sulphuric acid or 5N hydrochloric acid, but dissolve immediately in sulphuric acid of sp. gr. 1.84 and in hydrochloric acid of sp. gr. 1.2 with quantitative evolution of phosphine. With *aqua regia*, they apparently ignite and burn with a blue flame. The following method of analysis is advocated:—0.5 gm. of the sample, in the form of sawings which have been freed from adventitious particles of iron by means

of a magnet, is placed in a flask fitted with a tap-funnel and connected to a train of three absorption vessels, each containing 90 c.c. of 0.2% potassium permanganate solution and 10 c.c. of nitric acid (sp. gr. 1.12). A current of carbon dioxide or coal gas is then passed through the apparatus to remove the air, after which 30 c.c. of hydrochloric acid (sp. gr. 1.20) is admitted through the tap-funnel into the flask. The contents of the flask are boiled until the alloy is completely decomposed, and carbon dioxide or coal gas is again passed through the apparatus for 3 mins., after which, without stopping the flow of gas, the train is disconnected from the flask. A known weight, between 1 and 2 grms., of ferric chloride (free from ferrous salts) is added to the contents of the generating flask and the solution is titrated at once with standard potassium bichromate solution (containing 4.126 grms. of the crystals dried at 105° C. in 1 litre) using potassium ferricyanide as external indicator. 1 c.c. of the bichromate = 0.005 gm. Sn. The contents of the three absorption vessels are transferred to a 500 c.c. flask and boiled for one minute, removed from the hot plate, and potassium nitrite added in small portions until the solution is colourless. The liquid is boiled to expel nitrous acid, cooled to 50° C., and made slightly alkaline with ammonia. The precipitated manganese phosphate is dissolved in a minimum quantity of nitric acid (sp. gr. 1.12) and 10 c.c. added in excess. The solution is then heated to 85° C., 50 c.c. of clear ammonium molybdate solution added, and the liquid stirred vigorously for 5 mins. The yellow precipitate of ammonium phosphomolybdate is filtered and washed with an acid solution of ammonium sulphate until the washings give no brown colour with ammonium sulphide. The precipitate is then dissolved in 7 c.c. of ammonia (sp. gr. 0.88) and 15 c.c. of water, the filter being subsequently washed with water until the filtrate and washings have a total volume of about 60 c.c., and 10 c.c. of sulphuric acid (sp. gr. 1.84) is added. The solution is passed through a Jones' reductor charged with amalgamated zinc; 2 c.c. more sulphuric acid is added and the solution is passed a second time through the reductor, followed by 200 c.c. of water, and titrated with N/10 potassium permanganate, of which 1 c.c. = 0.00008829 gm. P. Control tests showed that the phosphorus in the alloy is completely evolved as phosphine and that the latter is completely oxidised to phosphoric acid by the permanganate solution. The time required for determining both tin and phosphorus when the sample has been weighed is 15 mins.—A. B. S.

Mercury; Simple method for the purification of ——. H. B. Dunncliffe. Chem. News, 1917, 116, 41–42.

THE mercury is distilled slowly from an ordinary glass retort supported with its neck vertically downwards on a retort stand. Through the tubulure of the retort, the stem of a dropping funnel suitably bent, and a piece of glass tubing, are passed, and packed in place by means of asbestos. The neck of the retort passes through a perforated glass cover, into a glass beaker, and a sheet of asbestos board is placed between the retort neck and the Fletcher burner. Asbestos paper is placed over the retort to prevent loss of heat. The mercury is fed into the retort at about the same rate as it distils (about an ounce in four minutes).—T. H. B.

Germanium; Occurrence of — in Missouri and Wisconsin blenders. G. H. Buchanan. J. Ind. Eng. Chem., 1917, 9, 661–663 (see also this J., 1916, 894).

ZINC oxide or blende was mixed with twice its weight of concentrated hydrochloric acid, and

chlorine was passed through the mixture, which was then distilled in a slow current of chlorine until about half its volume was obtained in the receiver. The distillate was diluted with an equal volume of water and any germanium present precipitated by passing hydrogen sulphide through it. The precipitate was collected, dissolved in hydrochloric acid, re-precipitated as before, dissolved in ammonia, the solution evaporated to dryness, the residue moistened with concentrated nitric acid, again evaporated to dryness, and then ignited. The residue was treated with a little water and hydrofluoric acid, saturated with potassium chloride, and allowed to stand in the cold for 15 mins. Germanium, if present, forms a greyish, gelatinous precipitate, soluble on heating or diluting the solution. Positive results were obtained with Joplin and Wisconsin Separator ores, with "Special leaded oxide of zinc" from Mineral Point, a Mexican ore (La Bufa), ore from Austinville, Va., and with New Jersey "XXX oxides." None of these ores contained more than 0.01% of germanium, but larger proportions were observed in the residues in the zinc retorts, as germanium is not very volatile at 1350° C. In zinc oxide furnaces, the germanium is converted into oxide and passes off with the zinc smoke into the bags.—A. B. S.

Metals: The passive condition of—J. Slapenhorst. *Z. physik. Chem.*, 1917, **92**, 238—254. *J. Chem. Soc.*, 1917, **112**, ii., 290—291.

Iron which has been rendered passive by the action of chromic acid becomes active under the influence of hydrogen dissolved in the metal. In this experiment, the hydrogen was generated electrolytically on the opposite side of a thin iron plate, the hydrogen diffusing through the plate to the surface in contact with the chromic acid solution. This change cannot be explained by the removal of dissolved oxygen or by the destruction of an oxide film. Under suitable conditions, the reverse change may be brought about by the diffusion of nascent oxygen. The potential assumed by a metal in a neutral electrolyte depends on the quantity of oxygen present in the solution. If the surface of the metal is renewed by grinding with an emery-wheel, the potential changes from that characteristic of the passive form to the value peculiar to the active form of the metal. Hydrogen and nitrogen tend to preserve the potential of the active form, but otherwise behave as indifferent gases. Oxygen, on the other hand, is not an indifferent gas. Both in the gaseous and dissolved states it exercises a very considerable influence on the electrode potential and conduces to the appearance and maintenance of the passive condition.

Nickel alloys resistant to sulphuric acid. R. Irrmann. *Metall u. Erz.* 1917, **14** [N.F. 5], 21—30, 37—42. *Z. angew. Chem.*, 1917, Ref., 210. (See also this J., 1916, 425.)

THE system Ni-Cu forms a single series of solid solutions. The maximum resistance to acid attack is found in the 50% alloy. On treatment with acid, nickel passes into solution, but very little copper. Ternary alloys of nickel, copper, and tungsten were examined. Nickel-tungsten can take up copper to a limited extent which diminishes as the proportion of tungsten increases. These ternary alloys are more resistant to sulphuric acid than the Ni-W alloys, especially the following:—2% W, 20% Cu; 5% W, 45% Cu; and 10% W, 15% Cu. Electrical resistance is high—in all mixtures greater than that of constantan. The tensile strength is high—up to 47 kilos. per sq. mm., and the alloys roll well, especially the

most acid-resistant. Resistance to corrosion by acid and electrical resistance increase with the tungsten content. A series of quaternary alloys (Fe, Cu, Ni, W) was prepared from ferro-tungsten; the introduction of iron led to increased resistance to acid corrosion and better working properties. Alloys high in copper and iron and low in tungsten are both cheap and resistant to cold sulphuric acid. Other mixings are better for warm acid solutions. The addition of 0.2% of tungsten to German silver doubles its resistance to corrosion; probably, however, this is only an apparent improvement due to the formation of a surface layer of sulphate. Nickel in Cu-Ni alloys appears to prevent solution of the copper, and in the ternary and quaternary alloys studied, this is still more marked, leading to the production of mixtures with excellent acid-resisting properties.—H. J. H.

FERRO-SILICON containing about 50% of silicon is produced by charging the blast furnace with ore and fuel and supplying a blast containing substantially equal parts by weight of oxygen and nitrogen.—W. R. S.

Iron and steel alloys; Deoxidation of—by ferro-silicon and silicon carbide. L. Treuheit, Elberfeld-Vanesbeck. Ger. Pat. 292,682, July 27, 1915.

COMPLETE deoxidation is effected by the addition of a mixture of cryolite and silicon compounds to the melt, which obviates the use of manganese or aluminium; e.g., equal weights of cryolite and ferro-silicon are placed in the ladle and the steel is poured on. The formation of blowholes and slag enclosures is almost entirely eliminated.

—H. J. H.

Iron; Production of a protective coating of mixed oxides on—A. Prettnner, Spandau. Ger. Pat. 298,207, Oct. 16, 1915.

THE articles to be treated are dipped in a melt of alkali polychromates or of a mixture of chromates and chromic acid. A coating of chromic and iron oxides is produced, the process requiring only a few minutes to complete. Excessive heating causes decomposition of the chromates and is to be avoided.—H. J. H.

Copper; Process of recovering —. F. J. Pope and A. W. Hahn, Douglas, Ariz. U.S. Pat. 1,232,080, July 3, 1917. Date of appl., July 29, 1914.

THE ore is leached with sulphuric acid whereby the copper and part of the iron and aluminium are converted into sulphates. The copper is deposited and the acid regenerated by electrolysis, the liquor being used again for leaching. To prevent fouling, a calculated quantity of liquor is withdrawn periodically and treated with material containing copper oxide to precipitate iron and aluminium. The filtered liquor is electrolysed and returned to the circuit.—W. R. S.

Copper alloys; Production of deoxidised —. Vereinigte Hüttenwerke Burbach-Eich-Dudelingen, Luxemburg. Ger. Pat. 297,859, June 24, 1916.

SUBSTANCES capable of combining with oxygen are added to the alloy in the melting bath. They should be in briquettes or in other form that can be easily added—metal filings, carbon, cyanides, water glass, borax, etc.—and should preferably be of such a nature as to produce a slag containing alkali manganosilicates.—H. J. H.

[Copper] slags; Process of treating —. J. B. Herreshoff, jun., New York. U.S. Pat. 1,231,349, July 3, 1917. Date of appl., Apr. 9, 1915.

THE molten slag is washed by agitating it with a series of baths (e.g., of copper matte) containing less copper than the original matte from which the slag was separated, each bath of the series containing less copper than the preceding one.—W. R. S.

Metals [lead, etc.]; Process for the recovery of — from ores. C. S. Vadner, Butte, Mont. U.S. Pat. 1,231,101, June 26, 1917. Date of appl., Nov. 18, 1916.

THE crushed oxide or roasted sulphide ore is treated with sulphur dioxide in presence of moisture. The excess of sulphur dioxide is oxidised by manganese peroxide, whereby lead is precipitated as sulphate. The insoluble portion is separated from the liquor and leached with a saturated solution of salt from which lead is recovered by precipitation with iron. The liquor is treated for the recovery of the dissolved metals.—W. R. S.

Ores; Conversion of ferrous to ferric sulphate in wet extraction of —. W. Borchers and A. Boever, Aachen. Ger. Pat. 298,342, Apr. 16, 1916.

PROCESSES for wet extraction from sulphide ores can be improved by conversion of the ferrous sulphate in the roasted ore to ferric sulphate. This may be effected by heating the roasted ore, mixed with iron hydroxide and water, in presence of air at 150°—200°C.; when the ferrous sulphate is in solution, the liquor may be concentrated with admixture of iron hydroxide and the crystalline product heated at 150°—200° in presence of air.—H. J. H.

Metal distillation furnace. E. E. Cherry, Assignor to M. Movshovitz, Trenton, N.J. U.S. Pat. 1,231,239, June 26, 1917. Date of appl., Mar. 30, 1917.

AN inclined retort is mounted within the combustion chamber of a distilling furnace, the roof of which is inclined at the same angle as the retort. Exhaust flues within the upper portion of the side walls communicate with the combustion chamber at a point near the front wall immediately below

the roof, and at their rear ends with each other and with a descending flue within the rear wall.—W. R. S.

Amalgamating process for recovering metals from ores. P. Kuehn, Detroit, Mich. U.S. Pat. 1,231,176, June 26, 1917. Date of appl., Dec. 17, 1912.

A BODY of mercury presenting an extended surface is surmounted by columns of ore pulp flowing quietly by gravity, with decreasing velocity, from the bottom of one to that of the other column. A gentle flow of ore pulp is maintained in proximity to the surface of the mercury without substantially agitating the pulp or disturbing the mercury, limiting the flow to a rate sufficient to keep in suspension the particles of lower specific gravity than the metals to be amalgamated.—W. R. S.

Metals; Process for electrolytically precipitating —. G. C. Westby, Ludwig, Nev., Assignor to Western Process Co. U.S. Pat. 1,231,829, July 3, 1917. Date of appl., Mar. 21, 1916.

A SLOWLY-SOLUBLE anode, such as iron, is employed in an acid solution, heavily charged at the commencement with the sulphate of the metal of which the anode is composed, and containing varying amounts of sulphur dioxide and copper sulphate, both electrodes being caused to rotate in the electrolyte.—B. N.

Gold coatings on metals; Electro-deposition of hard —. T. L. Tesdorf, Kiel. Ger. Pat. 298,687, Aug. 4, 1916.

THE metal article is covered with a thin deposit of gold from a potassium cyanide bath and then a second deposition is made from an acid solution of gold salts. A micro-crystalline gold deposit of unusual hardness and stability is produced.—H. J. H.

Tin-plate; Process of making —. F. Mueller, Vienna, Assignor to F. Mueller, Chicago. U.S. Pat. 1,231,285, June 26, 1917. Date of appl., June 18, 1914.

A PROCESS for tinning black plate on one side only consists in coating one side of the annealed and pickled plate with fat, dipping it into an acid copper solution, converting the copper deposit into copper sulphide, and subjecting the prepared plate to the tinning process.—W. R. S.

Tungsten, molybdenum, and tantalum, etc.; Production of alloys of — with highly infusible metals having oxides which cannot be completely reduced by hydrogen. E. Podszus, Neukölln. Ger. Pat. 293,952, Dec. 19, 1913. Addition to Ger. Pat. 292,483.

ALLOYS containing zirconium, thorium, boron, and titanium can be prepared by mixing the oxides with tungsten or other metal the oxide of which is reducible by hydrogen, and subjecting the mass to a current of ammonia in an electrically-heated furnace at a temperature at which the nitrides dissociate, followed by a rapid cooling to inhibit re-formation of nitrides. Pure alloys in compact form can be prepared by this process.—H. J. H.

Ores and the like; Apparatus for treating —. N. C. Christensen, Assignor to Holt-Christensen Process Co., Salt Lake City, Utah. U.S. Pat. 1,231,707, July 3, 1917. Date of appl., Mar. 30, 1915.

AN apparatus for leaching and sedimentation

comprises a vertical cylindrical tank with a central discharge opening at the bottom, an overflow rim launder at the top, a series of stationary superposed horizontal decks with openings alternately at the centre and the periphery, and rabble arms above each deck mounted on a central vertical revolving shaft, which move the ore through the openings on to a lower deck and finally discharge it. The ore is fed to the upper, and the leaching liquor to the lower part of the tank. Connecting-pipes provided in the periphery of the upper deck lead to the space above one of the lower decks.

—W. R. S.

Metal plates; Apparatus for treating and cleaning — [after tinning]. J. H. Cole, and Abertillery Works, Ltd., Abertillery. Eng. Pat. 107,552, Mar. 7, 1917. (Appl. No. 3391 of 1917.)

Classifying and concentrating apparatus for minerals and the like. W. W. Richardson, London. Eng. Pat. 107,927, Dec. 27, 1915. (Appl. No. 18,450 of 1916.)

Rabbles for mechanical roasting furnaces. W. Hommel, Zürich, Switzerland. Eng. Pat. 101,549, Sept. 18, 1916. (Appl. No. 13,238 of 1916.) Under Int. Conv., Mar. 6, 1915.

SEE U.S. Pat. 1,220,510 of 1917; this J., 1917, 509.

Lead plating metals; Processes for —. R. J. Shoemaker and J. C. McClintock, Topeka, Kans., U.S.A. Eng. Pat. 107,285, Aug. 7, 1916. (Appl. No. 11,138 of 1916.)

SEE U.S. Pat. 1,195,376 of 1916; this J., 1916, 1067.

Metals; Electrolytic recovery of — from their solutions, and apparatus therefor. U. C. Tainton and M. F. L. A. Aymard, Johannesburg, Transvaal. U.S. Pat. 1,231,967, July 3, 1917. Date of appl., Nov. 14, 1914.

SEE Eng. Pat. 12,669 of 1913; this J., 1914, 1013.

Gold and silver; Process for extracting — from ore containing gold, silver, and manganese dioxide. M. H. Caron, Weltevreden, Java. U.S. Pat. 1,232,216, July 3, 1917. Date of appl., Apr. 18, 1916.

SEE Eng. Pat. 101,665 of 1916; this J., 1916, 1161.

Replacing and thickening apparatus. Process of replacement [for treating slimes and pulp]. U.S. Pat. 1,231,409 and 1,231,410. See I.

Devaltering and replacement apparatus. U.S. Pat. 1,231,411. See I.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Electrolytic cell structure. H. B. Slater, Riverside, Cal. U.S. Pat. 1,231,955, July 3, 1917. Date of appl., Mar. 21, 1914.

SEVERAL tubular electrodes, with perforated walls for the passage of the electrolyte, are detachably and rigidly mounted in openings in a conduit by screw-threaded T-connections, the conduit extending into the receptacle of the electrolytic cell, and carrying off the electrolyte passing into the inner parts of the electrode tubes. The upper ends of the electrodes are closed by conducting

plugs, which are all connected to an electrical conductor. Each electrode tube is fitted with a sleeve of porous insulating material acting as a diaphragm.—B. N.

Furnace; Electric —. C. G. Miner, Berkeley, Cal. U.S. Pat. 1,232,362, July 3, 1917. Date of appl., Feb. 17, 1917.

The space between the outer and inner walls of the furnace is packed with heat-insulating material, and the space enclosed by the inner wall forms a reaction chamber in the form of two opposed "paraboloids." A crucible of conducting material, placed in the principal foci of the paraboloids, acts as a centre or common electrode for two arcs in series or in parallel. A second crucible may be substituted for the first one, and is adapted to co-operate with the upper electrodes to constitute a resistance heating device.—B. N.

Process of recovering copper. U.S. Pat. 1,232,080. See X.

Electro-deposition of hard gold coatings on metals. Ger. Pat. 298,687. See X.

Process for electrolytically precipitating metals. U.S. Pat. 1,231,829. See X.

Electric furnace for fixing nitrogen from the air. U.S. Pat. 1,232,179. See VII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Oil of turpentine from various species of pine; Optical activity of —. D. E. Tsakalotos. Gaz. Chim. Ital., 1917, 47, I., 285—287.

OIL of turpentine obtained from the Aleppo pine (*Pinus halepensis*), which is the variety cultivated in Greece, consists largely of dextrorotatory pinene, $[\alpha]_D = +47^\circ$ to $+48^\circ$, whereas the oil of turpentine derived from *P. maritima*, the variety cultivated in France, Spain, and Italy, has for its main constituent levorotatory pinene, $[\alpha]_D = -40.5^\circ$. According to Gildemeister (*Die ätherischen Öle*, 1913, II., 133), however, the oil of turpentine derived from the buds of the Aleppo pine consists largely of levorotatory pinene. The author has therefore examined a sample of the bud oil of this pine, and has found its specific rotation to be $[\alpha]_D = +39.4^\circ$. He finds that this variety of pine produces an essential oil, the principal constituent of which is dextrorotatory pinene, whatever the part of the plant, or the locality (Greece, Provence, Algiers), or the period at which the oil is distilled.—C. A. M.

PATENTS.

Pigment and process for making same. S. Kohn, Westfield, N.J. U.S. Pat. 1,231,617, July 3, 1917. Date of appl., July 18, 1916.

A PURPLE pigment is produced by adding a solution of a metallic salt (lead acetate) to a warm aqueous solution of an alkali (ammonium) salt of purpuric acid in presence of free alkali.—E. W. L.

Stencil emulsions; Method of preparing —. J. A. Bailey and H. E. Kalusowski, Washington, D.C., Assignors to Addressograph Co., Chicago, Ill. U.S. Pat. 1,231,554, July 3, 1917. Date of appl., June 27, 1916.

A HARD wax, such as paraffin, ceresin, or carnauba

wax, or a mixture, is melted with lanolin, and the mixture dissolved in a volatile solvent. The solution is then emulsified in a solution, preferably of gelatin, water, and glycerin, to which has been added a toughening agent such as potassium bichromate.—E. W. L.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchouc percentage in latex; Determination of —. Communication from the Netherlands Government Institute for advising the Rubber Trade and Industry. *India-Rubber J.*, 1917, 54, 95—96.

A RAPID method for determining the percentage of caoutchouc in latices is of the greatest importance on the plantation. Up to now three methods have been proposed:—(1) by means of densi-

mers; (2) by trial coagulations; (3) by determination of total solids, and deduction of a constant percentage for non-rubber compounds. Each of these methods has its disadvantages. Van Iterson has now devised an apparatus (see fig.) by means of which the caoutchouc content is estimated by comparing the opacity of a given sample of latex with that of a standard sample with which the instrument has been calibrated. The determination is carried out by adjusting the thickness of a central, circular film of latex, confined between an upper glass plate, *b*, and a lower ebony disc, *a*, until its colour matches that of an encircling annular surface, *c*, of a standard colour (oil-paint), applied to the under side of the observation glass. The adjustment is effected by moving the brass cylinder, *f*, up or down by means of the screw. The instrument is graduated to read direct in percentages of caoutchouc. With high concentrations the error may reach a few per cent., but with average and low concentrations the results are very satisfactory. —E. W. L.

XV.—LEATHER; BONE; HORN; GLUE.

Drum tannage. O. Riethof. *J. Amer. Leather Chem. Assoc.*, 1917, 12, 322—336.

For successful drum tannage of sole or belting leather, the hides must be pliable and therefore not too plump before entering the drum, otherwise tannage will be much retarded and the yield of leather very low; the pliability should be maintained throughout the process. The natural acidity of extracts is usually sufficient to make

and keep the stock sufficiently plump. It is further necessary to have the temperature low in the drum until the hides are well struck through; afterwards it is beneficial to let the temperature rise. Clear liquors should be used, since sediment fills up the pores and retards tannage. Oakwood extract should not be used until the final stages; if used too soon it causes a rapid surface tannage, and prevents tannin from reaching the interior, so that a raw streak in the leather may easily result. On analysis, drum tanned leathers usually show a lower degree of tannage than do leathers tanned in pits, though this does not necessarily indicate inferior quality. It is possible to get as high a yield of leather by drum tannage as by any other method.—F. C. T.

Tannery wastes; Purification of —. H. B. Donnon. *J. Amer. Leather Chem. Assoc.*, 1917, 12, 307—321.

In tests carried out at two large leather works, it was found that spent tan liquors were too concentrated to be economically filtered even when diluted and partly precipitated by other tannery liquors containing lime. The spent liquors were therefore treated with sludge from lime pits, the concentration being thus reduced by about one-half. Other liquors (including wash waters, lime liquors, waste from bleaching vats, etc.) were mixed and treated with ferrous sulphate (10 grains per gallon) which reduced their concentration considerably. The treated liquors were then combined and passed into settling tanks, where they remained for four hours, after which filtration was effected first by cinder filters (coke offers no advantage) and then by sand beds. By this treatment, suspended matter was reduced from about 1000 parts per million to 30, working at a rate of 250,000 and 200,000 gallons per acre per day for the cinder and sand filters respectively. The filtered effluent was only slightly coloured, and developed no odour on storage for 10 days in a warm room. Fish were able to live in it for over a month. The sludge from the settling tanks was black and finely divided, with little odour, and dried to a workable consistency in ten days when applied to a depth of ten inches over a bed of fine cinders one foot deep. The dry material contained about 2% of organic nitrogen, 20% of calcium as oxide, 0.3% of potassium as oxide, and 0.5—1.0% of phosphates, and proved to be a useful fertiliser. —F. C. T.

PATENT.

Tennis-gut; Process for manufacturing —. S. Kimata, Kobe, Japan. U.S. Pat. 1,231,911, July 3, 1917. Date of appl., June 10, 1916.

ANIMAL tendons are twisted into a string or cord, which is then degreased, bleached, impregnated with a mixture of sodium peroxide and magnesium sulphate, dipped into a mixture of gum treated in dilute sulphuric acid, and dried.—E. W. L.

XVI.—SOILS; FERTILISERS.

Soil solution. J. P. van Zyl. *J. Landw.*, 1916, 64, 201—275. *J. Chem. Soc.*, 1917, 112, i., 439—440.

VARIOUS methods of obtaining representative soil solutions were compared, and it was found that extraction by pressure gave the best results. Using this method, the soil from a particular field was studied in detail, samples being taken from a limed and from a dunged plot in summer and in

winter. These were subjected to pressure and the solutions obtained were analysed; the concentration of the solutions varied according to both the manurial treatment and the season of the year, but the percentage composition of the ash remained constant, thus lending support to the Cameron-Whitney theory of soil solution. The author points out that in order to get a true knowledge of the physical structure of a soil, its mechanical analysis should be carried out in its own soil solution. Comparative sedimentation tests were made, using distilled water and soil solution; when soil solution was employed the liquid cleared much more quickly, but fifteen washings only removed 2% of the clay; on the other hand, when distilled water was used, deflocculation was more complete and fifteen washings removed all the clay from the soil. Two series of mechanical analyses were then undertaken on the soil samples mentioned above (that is, limed and dunged plots in summer and winter); in one case distilled water was used and in the other soil solution. The results again showed evidence of the deflocculating action of the soil solution, so much so that the separation of the three finest fractions from one another was not attempted. These groups of three fractions (0.006 to 0.0005 mm.) were afterwards treated with distilled water and complete separation effected. It was found that the number of washings required for the operation varied from 80 to 120, was higher on the dunged plot than on the limed plot, and higher in winter than in summer.

Organic matter in the soil; Influence of soil conditions on the decomposition of —. E. J. Russell and A. Appleyard. *J. Agric. Sci.*, 1917, 8, 385—417.

OBSERVATIONS were made on field plots over a long period and determinations were made of the number of bacteria in the soil, the amount of nitrate in the soil water, and of carbon dioxide in the soil air, as being factors accompanying the decomposition of plant residues and other organic matter. The results were plotted in curves, and there was sufficient resemblance between all the curves to justify the conclusion that they were related. The curve for nitrate was always behind that for bacterial numbers, the lag amounting to 2—3 weeks, indicating that the stage of ammonia production must depend in part on organisms other than those counted or on some other factor. Decomposition does not take place below 5° C.; as soon as the temperature rises action begins and increases rapidly, but it is limited by the amount of moisture; in the summer, when the moisture in unmanured soil fell to 10%, decomposition was at a minimum. Decomposition was active after rain, due to the dissolved oxygen in the rain. The crop growing in the soil exerted a depressing effect on decomposition from causes not yet determined.—J. H. J.

Nitrification as a factor in soil fertility; Significance of —. P. L. Gainey. *Soil Sci.*, 1917, 3, 399—416.

CULTIVATED soils under normal conditions contain nitrifying organisms which transform ammonia into nitrate as rapidly as it is formed, as is shown by the fact that there is no accumulation of ammonia beyond a constant quantity. When conditions are abnormal and nitrification becomes impossible, then ammonia accumulates; and when conditions become normal again, the excess is rapidly nitrified. There is no relation between ammonia content and nitrifying power, nor between ammonia content and productivity; so that, although nitrification is associated with, and may be essential to, fertility, it is not the limiting factor.—J. H. J.

Soil bacteria and streptothrices: Are all the — that develop on dextrose-agar azoifiers? P. Emerson. *Soil Sci.*, 1917, 3, 417—421.

EXPERIMENTS were made to determine whether the organisms other than *Azotobacter* which grow on culture media free from nitrogen, are nitrogen-fixing organisms. The medium used was dextrose-agar without peptone and with added mineral salts. This was inoculated with dilutions of a soil suspension. The number of colonies capable of growing on this medium at the ordinary temperature was 2.4 millions per grm. of dry soil. The colonies on the plate cultures could be classified into four groups: a streptothrix group, a radiclecola group, a fluorescent group, and an opalescent group. Nitrogen-fixation experiments were made by inoculating sterile soil with cultures of the members of each group. At the end of three weeks, analysis showed that the amount of nitrogen in the cultures had increased on the average by 13—15 mgrms. per 100 grms. of air-dried soil. Only one organism failed to fix any nitrogen.—J. H. J.

Soil reaction; Effect of — on the availability of ammonium sulphate. R. C. Cook and F. E. Allison. *Soil Sci.*, 1917, 3, 487—498.

POT experiments with buckwheat were made on an acid soil supplied with ammonium sulphate, to determine whether lime was necessary to secure the production of sufficient nitrates to yield a good crop. It was found that small applications of lime produced as good a crop as a large application sufficient to neutralise all the acidity. The total crop on the more acid soils was smaller, but its percentage of nitrogen was higher, so that the recovery of nitrogen from an acid soil may be as great as from an alkaline one. The beneficial effects of lime were more noticeable on a sandy soil than on a silt loam. The addition of lime allows the soil nitrogen to be made available to a sufficient extent to satisfy the crop. Buckwheat was able to utilise the nitrogen from ammonium sulphate at an acidity equivalent to 3000—4000 lb. of lime per acre. Either the nitrogen was taken up directly as ammonia, or else there was much nitrification in the acid soil.—J. H. J.

Fixation of nitrogen in faeces. E. H. Richards. *J. Agric. Sci.*, 1917, 8, 299—311.

WHEN horse faeces is fermented aerobically in presence of moisture and calcium carbonate, there is a considerable fixation of nitrogen in varying amounts up to 30% of the nitrogen present originally in the faeces. Under the most favourable conditions 1 grm. of dry matter in the faeces fixes 4 mgrms. of nitrogen. The fixation varies with the diet of the animals, and faeces from animals fed on grass alone gave rise to no fixation of nitrogen. This is true of bullocks as well as of horses. The organisms concerned in the process were the same as those contained in garden soil, but *Azotobacter* alone did not bring about the fixation in quantity; it was necessary for *B. lactis aerogenes* to be present also.—J. H. J.

Peas; Influence of mineral matters on the germination of —. L. Maquenne and E. Demoussy. *Comptes rend.*, 1917, 165, 45—51.

COMPARATIVE experiments on the rate of germination (rootlet growth) of peas in sand moistened with solutions of salts of various metals, indicate that calcium exerts a much greater accelerating influence than other common metals.—J. H. J.

Smelter smoke problem; Results of recent investigations of the —. A. E. Wells. *J. Ind. Eng. Chem.*, 1917, 9, 640—646.

RECENT investigations have shown that the

damage to vegetation by dust and fume particles and acid mist from smelters is practically negligible. The recovery of solid matter from the smoke evolved in smelting lead, copper, and zinc ores may be made remunerative because of the value of the recovered material. The recovery of sulphurous gases is important because of their damage to vegetation, even 1 part of sulphur dioxide per million parts of air being injurious to the colour though not necessarily to the growth of the crops. Before injury to plants occurs with air containing sulphur dioxide, four factors must operate simultaneously in sufficient amount, namely, light (plants are not injured by this gas at night), humidity, wind prevalence, and temperature. Thus, air containing 1 part of sulphur dioxide per million, with a humidity of 70% and at a temperature of above 4° C., must remain for 3 hrs. in contact with the plants in daylight for bleaching to occur. The concentration of the sulphur dioxide is reduced by the use of a high chimney. It is better to discharge the chimney gases into the atmosphere at a high temperature after removing 85% of the impurities than to obtain a greater purification and discharge them at a much lower temperature. With a concentration of 0.45% of sulphur dioxide, the gases being discharged at 65% purification from a chimney 450 ft. high, the possibility of injury to vegetation appears to be negligible. It is desirable to ascertain the periodical occurrence of the critical times when all the factors resulting in injury to vegetation are present and to curtail the production of sulphur dioxide at these periods. Experiments in which the sulphuric acid, sulphur dioxide, and sulphur recovered from the chimney gases were used as fertilisers have proved successful, some of the treated crops yielding double the normal amount.—A. B. S.

Calcium phosphates; Solubility of — in citric acid. A. A. Ramsay. J. Agric. Sci., 1917, 8, 277—298.

NUMEROUS analyses were made of samples of calcium phosphate of commerce and of the same substance prepared by the methods usually recommended. It was found that the substances sold as "phosphate of lime" and "calcii phosphas B.P." were mixtures of di- and tri-calcium phosphates. Disodium phosphate added to ammoniacal calcium chloride, and bone ash dissolved in hydrochloric acid and precipitated with ammonia, both yield mixtures of di- and tricalcium phosphates and calcium hydroxide. When three equivalents of lime are made to act on one equivalent of phosphoric acid and the precipitate is filtered off at once, pure tricalcium phosphate is obtained; but when two equivalents of lime are used, the product is a mixture of di- and tricalcium phosphates. With regard to solubility in the prescribed 2% citric acid solution, it was found that 1% of the total phosphoric acid in pure tricalcium phosphate was soluble after 30 mins. shaking, but that the addition of calcium carbonate reduced the solubility to 84%. Extraction with the citric acid solution is not an exact criterion of the availability of the phosphoric acid, since the availability was reduced from 91% to 84.5% by the addition of 14% of lime as carbonate, and to 4.3% by addition of a further 14%. The citric acid is a solvent for the lime rather than the phosphoric acid, since all the lime not present as tricalcium phosphate is extracted. Dicalcium phosphate is soluble in the citric acid solution, so that it is not possible to distinguish between the di- and tricalcium phosphates by this solvent, and therefore the use of citric acid as indicating the manurial value of phosphates is questionable.—J. H. J.

Manganese slag; Manurial experiments with —. M. Popp. Pöhlings Landwirtsch. Zeit., 1916, 65, 354—360. Bull. Agric. Intell., 1916, 7, 1600—1601.

THE manufacture of ferromanganese and spiegel-eisen in Germany yields as by-product large quantities of manganese slag, of which the average composition is:—24.4% Mn, 30.5% SiO₂, 9.8% Al₂O₃, 33.4% CaO, 6.3% MgO, 1.2% S, and traces of iron. The manganese is insoluble in water but slowly soluble in weak acids. A series of pot experiments were carried out to compare its manurial value with that of anhydrous manganese sulphate. White Petkus oats were sown in pots each containing 10 kilos. of sandy soil (with 0.28% CaO, 0.14% P₂O₅, 0.13% K₂O, and 0.15% N), which received further 1.5 grms. of potash, 1 gm. of phosphoric acid, 1.5 grms. of nitrogen, and 60 grms. of calcium carbonate in the form of marl, besides dressings ranging from 0.5 to 10 grms. of manganese either as finely powdered slag or as sulphate. The manganese slag increased the yield of both grain and straw, and the increase was greater the larger the amount applied, except for the maximum dressing (10 grms.). In small amounts (0.5 and 1 gm.) the sulphate was more effective than the slag, but with the larger dressings (2.5 and 5 grms.) the reverse was the case. With manganese slag the yield of grain was affected more than that of straw, whilst the sulphate affected the yield of straw most.—J. H. L.

Phosphoric acid determinations in phosphate rock. C. C. Semple. Eng. and Min. J., 1917, 103, 1140—1141.

FROM $\frac{1}{2}$ to 1 gm. of the phosphate rock is decomposed by means of nitric and hydrochloric acids, and the silica is removed by evaporating twice to dryness in the customary manner. The dried mass is taken up by 10 c.c. of concentrated hydrochloric acid and after dilution with boiling water, the solution is filtered from the insoluble matter, and the latter is washed until the bulk of the filtrate and washings measures 175—200 c.c. Ammonia is added, with constant stirring, to this filtrate until a gelatinous precipitate of calcium, iron, and aluminium phosphates begins to form, and then 30 c.c. of ammonia solution (sp. gr. 0.9) is added in excess and the whole stirred vigorously; 10 c.c. of a saturated solution of citric acid is now added, and the solution is stirred for 2 minutes, at the end of which time, if the precipitated phosphates have not redissolved, more citric acid solution is added, drop by drop, until the phosphate solution is quite clear. 30 c.c. of the magnesium mixture is now added, and the solution is stirred until the precipitate of magnesium ammonium phosphate begins to form; after standing for three hours it is filtered. The volume of citric acid required to clear the solution is proportional to the amount of phosphoric acid present in the liquid, and by use of a solution of citric acid of known strength for this purpose, an approximate idea of the strength of the sample may be obtained. The results agree closely with those obtained by the molybdate method.—J. B. C. K.

Blood; Adulteration of dried —. M. Sirot and G. Toret. Ann. Falsif., 1917, 10, 220—227.

THE valuation of dried blood for use as a manure is discussed, and it is pointed out that, in its sale based on the "organic manure" content, the latter should not include any hide, etc., mixed with it. The content of nitrogenous matter is determined by multiplying the nitrogen content by the necessary factor (for hide, 6.25; for horn, 5.95); the content of organic matter is calculated by difference after determination of moisture and

mineral content. In all the adulterated samples examined the difference between the percentage of organic matter and of nitrogenous matter exceeded 3.5. In case hide only has been added, differences of 4.5, 8.0, and 11.5 correspond to 10, 20, and 30% of hide respectively.—F. W. A.

Manuring of sugar cane in Java. Comparative results with calcium cyanamide and ammonium sulphate. Geerts. See XVII.

Fertiliser material; Process of producing —. Process for treating distillery by-products. W. W. Haughey, Assignor to By-Products Reclaiming Corporation, New York. U.S. Pats. (A) 1,232,032 and (B) 1,232,416, July 3, 1917. Date of appl., Nov. 11, 1916.

DISTILLERY "slop" is (A) concentrated, dried at about 300° F. (about 150° C.), and then roasted at about 700° F. (about 370° C.) to render the material non-hygroscopic without driving off the nitrogen; or (B) continuously concentrated, dried in thin films, and roasted at a predetermined temperature—about 700° F.—sufficient to render the material non-hygroscopic without driving off the nitrogen.—E. W. L.

Fertilisers; Process for manufacturing —. W. D. Richardson, Assignor to Swift and Co., Chicago, Ill. U.S. Pat. 1,232,452, July 3, 1917. Date of appl., Aug. 28, 1915.

The insoluble potash in silicate rock is rendered soluble by mixing with calcium phosphate and a fluoride (fluoride material containing calcium phosphate) together with an acid capable of decomposing fluoride, conveying the mixture to a den or pile to complete the reaction, and afterwards drying it.—E. W. L.

Superphosphate reaction chambers; Apparatus for emptying —. H. W. Hall, Zürich, Switzerland. U.S. Pat. 1,232,295, July 3, 1917. Date of appl., Feb. 6, 1915.

See Eng. Pat. 2077 of 1915; this J., 1915, 881.

XVII.—SUGARS; STARCHES; GUMS.

Sugar cane cultivation; The effect of lime in —. W. E. Cross. Revista Industrial y Agrícola de Tucumán, 1916, 7, 173—178. Intern. Sugar J., 1917, 19, 312—315.

By the application of lime to soils in Tucumán, Argentina, a total increase of 26.1 tons of cane was obtained, or nearly 2 tons of sugar per hectare, as compared with plots not so treated. In this Province the soils are particularly deficient in this constituent, and the experiments undertaken indicate that this fact may explain in a certain degree the almost negative results which fertiliser experiments have generally hitherto given there.—J. P. O.

Sugar cane in Java; Manuring of —. Comparative results with calcium cyanamide and ammonium sulphate. J. M. Geerts. Arch. Suikerind. Nederland. Indie, 1916, 24, No. 44. Bull. Agric. Intell., 1917, 8, 244—245.

In 59 out of 78 comparative trials with ammonium sulphate and calcium cyanamide, during 1905—

1914 in Java, the former gave better results than the latter, yielding on the average 2.5% more cane and 2% more sugar. It appears probable that calcium cyanamide gives better results in light than in heavier soils, but in both cases it is less satisfactory than ammonium sulphate. In using calcium cyanamide it is best to apply a portion before planting. If, for example, a portion is given not less than a week before planting and the remainder in 3 or 4 lots at intervals after planting, without allowing it to touch the plants, the cyanamide is decomposed before it reaches the rootlets and there is scarcely any danger of injurious action. Partial substitution of cyanamide for ammonium sulphate is better than complete substitution, but the cyanamide should always be applied before the sulphate. Cyanamide has no influence on the ripening of the cane.

—J. H. L.

Sugar estimation; Modification of Fehling's method of —. E. Lenk. Deutsch. Med. Woch., 1917, 43, 43—44. J. Chem. Soc., 1917, 112, ii., 341—342.

The addition of 1 mgrm. of magnesium sulphate to each c.c. of the copper sulphate solution ensures rapid sedimentation of the colloidal cuprous oxide. Calcium salts are harmful in this respect. For example, on adding urine, drop by drop, to boiling Fehling's solution containing magnesium, the cuprous oxide suddenly cakes together and the next drop makes the solution perfectly clear; this point corresponds with the disappearance of copper from the solution, and is therefore the true end-point.

Sucrose and invert-sugar; Conservation of solutions of — by means of various antiseptics. H. Pellet. Bull. Assoc. Chim. Sucr., 1916, 35, 136—138.

HALF-LITRE portions of 5% sucrose solution were treated respectively with 0.5 gm. of thymol, 2 c.c. of toluene, 5 grms. of sodium fluoride, and 1.7 gm. of sodium salicylate, and left at the ordinary temperature. Some inversion occurred in presence of sodium salicylate within 2 days; only the solution containing thymol remained unaltered for 13 days, and that showed signs of hydrolysis within 20 days. In similar tests made with 5% neutral solutions of invert-sugar, the rotatory power remained unchanged in all cases for 38 days, though slight growth of mould was visible in the solution containing sodium fluoride. The experiments were made as a guide in the use of antiseptics for inversions by means of invertase at the ordinary temperature, which sometimes occupy 8—10 days.—J. H. L.

Molasses; Influence of amino-acids and of l-glutamic acid in the estimation of raffinose and sucrose in — by the inversion method. V. Staněk. Z. Zuckerind. Böhm., 1916, 41, 154—160. J. Chem. Soc., 1917, 112, ii., 342.

The presence of glutamic or l-glutamic acid diminishes the amount of sucrose found in all cases in which the ordinary methods of estimation are employed, only acid polarisation and the Clerget-Herzfeld formula giving accurate results. Aspartic acid increases the amount of sucrose given by ordinary direct polarisation or by inversion and polarisation. Acid polarisation gives correct results if the Clerget-Herzfeld formula is used, but the raffinose formula gives low numbers. In presence of aspartic or glutamic acid a positive amount, and in presence of l-glutamic acid a negative amount, of raffinose is indicated when this sugar is absent; the errors thus incurred are halved when acid polarisation is used. With pure

beet molasses it is well to discard the raffinose formula entirely and to determine the sugar content by the acid polarisation method and application of the Clerget-Herzfeld formula. No method is known by which raffinose may be estimated in presence of amino-acids.

Raffinose: Influence of — contained in beet molasses, on the determination of sucrose by double acid polarisation or by inversion with invertase. H. Pellet. Bull. Assoc. Chim. Sucr., 1916, 35, 112—117. (See also this J., 1917, 153.)

SAMPLES of beet molasses were found to contain 0.7—1.5% of raffinose by the method of Hudson and Harding (this J., 1915, 1065). The determination of raffinose in presence of sucrose by double polarisation and application of Herzfeld's raffinose formula, is vitiated by the presence of other optically active substances even if these remain unaffected by inversion, as is the case when invertase is used and the readings before and after inversion are made on neutral solutions (cp. Ogilvie, this J., 1911, 62). It is shown, for instance, from the known constants relating to raffinose and sucrose, that if a molasses contains non-sugars which influence the polarisations before and after inversion to the extent of -3 sugar degrees, the apparent sucrose-content, calculated by means of the raffinose formula, will be higher than the direct polarisation in spite of the presence of 1 or 2% of raffinose. The ordinary inversion formula:—

$$\text{Sucrose \%} = 100 (P - P_1) / (142.66 - t/2),$$

gives results higher than the true sucrose-content, to the extent of 0.67% for every 1% of anhydrous raffinose present, irrespective of the presence of other optically active substances which are not changed by inversion. If the raffinose-content is determined independently, e.g., by Hudson and Harding's method, and the direct polarisation and apparent sucrose-content (calculated by the above formula) are corrected accordingly, their difference will represent the rotation of the optically active substances present other than sucrose and raffinose. The author has compiled a short table showing the combined effects of 0.7—1.5% of raffinose and 0—3% of levorotatory non-sugars on the polarisation and apparent sucrose-content of molasses containing 44% of sucrose.—J. H. L.

Beet-molasses; Pentose-content of —. H. Pellet. Bull. Assoc. Chim. Sucr., 1916, 35, 117—121.

APPLYING the methods of investigation previously described (see this J., 1916, 1075), the author concludes that beet molasses normally contains no appreciable quantity of pentoses. It is probable, however, that small quantities of pentosans are present, as stated by Stiff and Komers (see this J., 1898, 475), who found 0.47—1%. The small amounts of reducing sugars often found in vinasses from beet molasses do not represent non-fermentable sugar, but probably consist of invert sugar which has escaped fermentation owing to the high alcohol-content and acidity of the vinasses at the close of fermentation.—J. H. L.

Molasses; Nitrogenous pigments of —. V. Staněk. Z. Zuckerind., Böhm., 1917, 41, 298—306. J. Chem. Soc., 1917, 112, i., 381—382.

WHEN dried molasses is extracted with alcohol, there remains undissolved a small percentage of non-saccharine substances which contain about 94% of the total pigment and 10% of the nitrogen of molasses. The author has separated the residue into various fractions. One of them apparently contains a fairly definite substance which is pre-

cipitated by lead acetate, is soluble in alcoholic hydrogen chloride solution, but not in ether, and contains 7.1—7.3% of nitrogen and about 0.2—0.3% of ash. It seems to be a product of the condensation of amino-acids with sugars, and is designated fuscazinic acid. The alkali salts of this account for about half of the colour of molasses.

Starch; Direct method for the estimation of —. T. von Fellenberg. Mitt. Lebensmittelunters. Hyg., 1916, 7, 369—383. J. Chem. Soc., 1917, 112, ii., 342—343.

THE method depends on the solubility of starch in calcium chloride solution, its precipitation by iodine, and the decomposition of the precipitate by alcohol. From 0.3 to 1.0 gm. of the finely-divided, fat-free substance under examination is moistened with water and mixed with 20 c.c. of 50% calcium chloride solution; the mixture is heated in a boiling water-bath for thirty minutes, then boiled for five minutes, cooled, diluted to 100 c.c., and filtered through cotton-wool and then through asbestos. If the filtrate is not perfectly clear, it must be submitted to centrifugal action. Fifty c.c. of the filtrate is treated with N/50-iodine solution until a flocculent precipitate is obtained; a large excess of iodine is to be avoided. After about twenty-four hours a quantity of asbestos is added, the precipitate and asbestos are collected in a Gooch crucible containing a layer of asbestos, and the contents of the crucible are washed four times with 5% calcium chloride solution containing a few drops of iodine solution. The precipitate is then washed with 60% alcohol (this is allowed to act on the precipitate for five minutes), then with 85% alcohol, and finally with 100 c.c. of 90% alcohol. If the contents of the crucible are not now colourless, a quantity of hot alcohol is added. After further washing with cold 95% alcohol, 5% calcium chloride solution, and dry ether, the crucible and its contents are dried, weighed, ignited, and re-weighed. The loss in weight gives the quantity of starch present.

PATENT.

Sugar-washer; Automatic — and reater-measurer for the same. J. Sailer, Oxnard, Cal. U.S. Pat. 1,230,328, June 19, 1917. Date of appl., May 5, 1915.

THE apparatus comprises a "film nozzle" through which the washing fluid is fed against the charge of sugar in the centrifugal machine, means for holding the nozzle in its extreme upper position so that it is clear of the basket and for reciprocating it between its extreme lower position inside the basket, and an intermediate position near the top of the basket. The actuating device comprises a main cylinder and piston, a nozzle carried by the piston, a water supply to the nozzle, valves for applying pressure to raise or lower the main piston, an auxiliary piston which actuates the valves, and means whereby the main piston automatically controls the pressure on the auxiliary piston.—J. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Wines; Sulphurous acid in chemical combination in musts and —. Laborde. Rev. Viticulture, 1916, 45, 309—314, 373—376, 421—423, 437—440, 453—459. Bull. Agric. Intell., 1916, 7, 1676—1685.

WHEN quantities of 160 or 200 mgrms. of sulphur

dioxide per litre are added to grape must, by far the greater part enters into combination, chiefly with dextrose; though also to some extent with non-sugars, but not with levulose. The ratio of free to combined sulphurous acid increases with the amount added, but is not appreciably affected by changes in the acidity of the must nor by the direct action of *Botrytis cinerea* (cp. Müller-Thurgau and Osterwalder, this J., 1915, 1066; 1916, 900). In spite of the greatly reduced antiseptic properties of sulphur dioxide in the combined form, its presence in a fermenting must can modify the physiological action of the yeast; the production of aldehydes is increased (cp. *loc. cit.*), the rate of fermentation is slightly reduced, especially at first, and to a greater extent at 25° than at 15° C., and the yeast appears to ferment rather more levulose than dextrose. In respect of the proportion of added sulphur dioxide which enters into combination, cheap table wines (*vin ordinaire*) do not differ very much from the musts which produce them; but musts infected with *Botrytis cinerea* and very rich in sugar, generally yield sweet wines of much lower combining power, very much the same as that of *vin ordinaire*. The addition of sulphur dioxide to a must changes but little the combining power of the wine produced from it (*i.e.*, with respect to further additions), for the initial quantity is taken up by aldehyde formed during fermentation. The checking of fermentation may be effected in contact with living yeast without using excess of sulphurous acid, so long as sufficient is added to stop the fermentation completely and the lees are withdrawn as speedily and completely as possible to diminish risk of slow secondary fermentation, which would produce aldehyde and so reduce the amount of free sulphur dioxide. Since the total amount of added sulphur dioxide is subject to statutory limitation and only the free acid inhibits fermentation, it is important to avoid those conditions which favour the production of substances capable of combining with the acid; among these conditions are excessive aeration, too prolonged fermentation, precipitation in presence of sulphurous acid, and secondary fermentation after sulphiting. During 3 or 4 years (the normal period of preservation of wines) a certain increase in the amount of combined sulphur dioxide must be expected.—J. H. L.

Pentose-content of beet-molasses. Pellet. See XVII.

PATENTS.

Worts, fermented and distilled beverages, and other products resulting from the mashing of starchy materials; Manufacture of —. Wahl-Henius Research Laboratory, Assignees of R. Wahl, Chicago, Ill., U.S.A. Eng. Pat. 101,406, Apr. 7, 1916. (Appl. No. 5153 of 1916.) Under Int. Conv., Sept. 9, 1915.

MATERIALS such as wheat bran, offal of pearl barley, cortex of maize, and certain products of the milling of dried peas and beans, which contain translocation diastase and considerable amounts of proteins and phosphates, are used in place of malt as saccharifying agents in the preparation of mashes and worts for the manufacture of beers, spirits, non-alcoholic beverages, vinegar, etc. For example, beers may be prepared from wheat bran and cooked amylaceous materials, since under suitable conditions bran will saccharify 2 or 3 times its weight of gelatinised starch. The required malt flavour may be imparted by caramel malt or other known preparations, or bran which has been moistened and heated to 150°–200° C. may be used for flavouring. To render soluble the nitrogenous and phosphatic constituents of the saccharifying agents mentioned, the mashes may be acidified by addition of lactic acid or by use of

lactic bacteria (cp. U.S. Pat. 1,028,508; this J., 1912, 655) and held at temperatures favourable to proteolysis; or wheat bran which has been thus mashed with acid and subsequently dried may be used instead of raw bran. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 2587 of 1896; this J., 1896, 368.)—J. H. L.

Hops; Extraction of oils and resins from —. F. W. Wolff, London. Eng. Pat. 107,155, Nov. 9 and Dec. 13, 1916. (Appl. Nos. 16,104 and 17,932 of 1916.)

Hops are exposed to the action of steam containing alcohol vapour, to dissolve out the resins and volatilise the oils, at temperatures below that at which the resins would become hardened. The hops may be subjected, first, at a temperature below 100° C. to the action of a current of vapour of low alcohol-content (*e.g.*, produced by passing steam through 8% alcohol) by which the oils are volatilised and carried over into a separate vessel; next, at a low temperature to the action of vapours of high alcohol-content (*e.g.*, produced by passing steam through 67% alcohol), which condense on the hops and extract the soft resins, and finally the hops are submerged in warm water (with or without a small proportion of alcohol) and acted upon by vapours of low alcohol-content to dissolve the hard resins. The first operation may be omitted and the oils and soft resins extracted together by condensed vapours of high alcohol-content and afterwards recovered separately from the extract, the hops then being treated as before to extract the hard resins. An apparatus for carrying out the process is also claimed, consisting of a jacketed still in which the hops are supported on a perforated false bottom. For the volatilisation of the oils, heating liquid is circulated through the jacket, and the alcoholic steam is injected below the layer of hops so that it passes upwards through them to the still-head, which is connected with a condenser. For the extraction of the soft resins, cooling liquid is circulated through the jacket, the still-head outlet is closed, and the alcoholic vapour is admitted above the layer of hops and drawn off, after condensation, from the bottom of the still. Several features of minor importance are also claimed.—J. H. L.

Water [for brewing]; Process for eliminating carbonate hardness of —. G. Hess, Vienna. Ger. Pat. 297,873, June 25, 1914. Under Int. Conv., June 4, 1914.

SULPHATES of aluminium, iron, or other trivalent alum-forming metals are added to the water to convert alkali or alkaline-earth carbonates into alum or sulphates. Water thus treated yields light-coloured and highly palatable extracts in brewing. The excellent brewing properties of the water at Pilsen are ascribed to the presence of aluminate in the neighbouring rock strata. Water so treated has proved satisfactory in the extraction of sugar from beetroots.—H. J. H.

Hops; Process of leaching out —. H. Schneider, Essen, Germany. U.S. Pat. 1,232,098, July 3, 1917. Date of appl., Aug. 17, 1912.

SEE Fr. Pat. 447,382 of 1912; this J., 1913, 248.

Process of producing fertiliser material. Process for treating distillery by-products. U.S. Pats. 1,232,032 and 1,232,446. See XVI.

XIXa.—FOODS.

Beef; Changes in fresh — during cold storage above freezing-point. R. Hoagland, C. N. McBryde, and W. C. Powick. U.S. Dept. Agric., Bull. No. 433, Feb. 15, 1917, pp. 100.

SAMPLES of beef were kept in cold storage at temperatures above freezing-point for periods ranging from 14 to 177 days. It was found that the principal chemical changes were increases in the acidity, protease, non-coagulable, amion, and ammoniacal nitrogen, and in the soluble inorganic phosphorus; whilst decreases took place in the amounts of coagulable nitrogen and soluble organic phosphorus. There was also a pronounced increase in the acid value of the kidney and external fats. These changes were, in the main, progressive, and were of similar character to, though less pronounced than, those which took place when lean beef was autolysed under aseptic conditions for periods of 7 to 100 days. The chemical changes in the muscular tissue had no appreciable effect upon the wholesomeness or nutritive value of the beef, but the changes in the kidney fat and external fatty tissue after the longer periods of storage rendered those parts unfit for food. Bacteria and moulds which developed upon the surface did not penetrate the muscular tissue to any great depth, and the increased tenderness of meat which has been stored cannot be attributed to bacterial action. The chemical changes may be attributed largely to enzymic action. In practice beef is ordinarily stored at a temperature between 34° (1° C.) and 36° F. (2° C.), whilst 40° F. (4.5° C.) is regarded as the upper limit of safety. The condition of the beef is an important factor in the practicable length of storage, the meat from prime grain-fed cattle keeping much better than that from old animals or grass-fed cattle. Another factor is the degree of humidity. For example, beef could be kept for 177 days in an experimental cooler with 0 to 85% of humidity, whereas it could only be kept for 55 days in a modern packing house cooler with 92 to 95% of humidity.—C. A. M.

Potatoes; Desiccation of — in Germany. Parow, Georgine, Königsberg, 1916, 572. Bull. Agric. Intell., 1916, 7, 1685—1686.

THE number of factories for drying potatoes in Germany increased from 3 in 1903 to 488 in 1914; in 1916 there were 841, of which 551 were in the provinces of Brandenburg, Pomerania, Posen, and Silesia. With the present number of factories working day and night for 200 days, 12 million tons of dried potatoes can be produced from 30 million tons of raw material, but this output does not meet the requirements for cattle as well as human beings. The technology of desiccation is made rapid strides. Roller apparatus (*Walzenapparate*) and drum driers (*Trommelapparate*) are now generally used. The former can deal with 1.2—1.5 tons of potatoes an hour and the latter with quantities up to 5 tons an hour. The product can be preserved almost indefinitely. It is made in the form of flakes and cubes for cattle, and various flours for human consumption. The machines are easy to run, those of medium size requiring 8—10 H.P. and the larger ones 15—25 H.P. On an average, 12—14 tons of coal is used for 100 tons of potatoes, for the flaked product, and 8—10 tons of coke for cubes. Machines for making cubes can be used also for drying beetroots, peas, cereals, grass, and other vegetables.—J. H. L.

Cottonseed meal; Nutrition experiments with —. H. A. E. Richardson and H. S. Green. J. Biol. Chem., 1917, 30, 243—258. (See this J., 1916, 860.)

THE protein in a diet containing 50% of refined

cottonseed flour, protein-free milk, and butter-fat is sufficient for the normal growth of the albino rat and for reproduction to the third generation, but more general well-being and fertility was obtained by the addition of 5% of casein to the diet. The cottonseed flour employed contained 51% of protein and 11.4% of fat. Normal growth is not obtained with a diet of 50% of cottonseed flour in which there is a deficiency of butter-fat or protein-free milk; but 50% of cottonseed flour with 5% of casein and butter fat, without additional mineral other than that furnished by the cottonseed flour, supports normal growth and reproduction, although the second generation does not grow quite normally on this diet. No toxic effect is apparent in feeding 15—50% of cottonseed flour through prolonged periods and several generations, but the addition of the petroleum spirit extract of the entire cottonseed to a well-balanced diet has a depressing effect on the weight of the rat. The ethyl ether extract of the petroleum-extracted seed and the ethyl ether extract of the refined cottonseed flour have, on the other hand, no harmful effect. The addition of crystallised gossypol is injurious.—J. F. B.

Milk product; Self-preserving acid — and process of making the same. W. P. M. Grelek, Evanston, Ill., Assignor to B. H. Grelek, Lincoln, Nebr. U.S. Pat. 1,230,179, June 19, 1917. Date of appl., May 10, 1915.

SOURD milk is heated to precipitate the casein, and simultaneously agitated to prevent aggregation of the precipitate; heating may be continued at a higher temperature until the finely-divided particles of casein become permanently non-adherent, after which the surplus fluid may be evaporated.—J. H. L.

[Milk]; Composition of matter for preparing foods, and process of making the same [from —]. H. W. Wiley, Washington, D.C. U.S. Pat. 1,230,452, June 19, 1917. Date of appl., Mar. 7, 1917.

SKIMMED milk is strongly acidified, e.g., by means of *B. Bulgaricus*, and then rendered homogeneous and quickly dried. The dry powdered product may be mixed with a carbonate or bicarbonate and a filler of dried milk.—J. H. L.

Food composition [containing milk and cocoa]. J. M. W. Kitchen, East Orange, N.J. U.S. Pat. 1,230,091, June 12, 1917. Date of appl., Nov. 20, 1916.

POWDERED cocoa seeds and a thickening material, e.g., a powdered cereal, are mixed with skimmed milk; the product may be partially desiccated under reduced pressure. Claim is particularly made for the dehydration of mixtures of skimmed milk and powdered cocoa seeds under reduced pressure, whereby a thorough emulsion is secured.—J. H. L.

Coffee substitute. W. A. Lorenz, Hartford, Conn. U.S. Pat. 1,230,184, June 19, 1917. Date of appl., Aug. 2, 1916.

CLAIM is made for products consisting of granulated roasted cotton seeds and granulated roasted vegetable colouring and flavouring matters, and in particular for one made from granulated roasted cotton seeds, rye, and figs.—J. H. L.

Fruits and vegetables : Method of preserving — fresh. H. C. M. Franks, Brooklyn, N.Y. U.S. Pat. 1,232,271, July 3, 1917. Date of appl. Apr. 21, 1917.

The fruit is placed in a container which can be hermetically sealed, and is introduced into a pressure apparatus into which carbon dioxide is forced at a pressure of 60—70 lb. per sq. in., which is maintained for 10 mins. The pressure is then gradually released and gas and air are pumped out of the apparatus to a vacuum of about 16 in. of mercury. Carbon dioxide is allowed to enter the apparatus slowly again to the same high pressure, which is maintained for 1 hr. The apparatus is slowly evacuated, and the vessel containing the fruit is sealed before removal. The second treatment with carbon dioxide may be replaced or followed by a similar treatment with nitrogen.—J. H. J.

Coconut ; Process of preparing or treating —. F. Baker, jun., Philadelphia, Pa. U.S. Pats. 1,203,364, 1,203,365, and 1,203,366, June 19, 1917. Dates of appl., (A) May 11, (B) and (C) June 17, 1916.

(A) COCONUT is preserved in a natural, moist, condition, by separating the milk from the kernel, hermetically sealing the cut, grated, or shredded kernel, together with a portion of the milk (which may first be heated, e.g., at 100° C.), in suitable receptacles, and sterilising by heating, e.g., at about 220° F. (104·5° C.) for half an hour. (B) Coconut kernels, cut, grated, or shredded, are packed in receptacles, which are then subjected, open, to the action of steam at a temperature not exceeding 250° F. (121° C.), e.g., 220° F., to destroy bacteria, and afterwards hermetically sealed and heated for a short time at a temperature not exceeding 250° F. (C) The process is similar to (A), except that instead of coconut milk, aqueous sugar solution is introduced into the receptacles. The sealed receptacles may be finally heated for a short time at a temperature not exceeding 250° F.—J. H. L.

Cereal food ; Process of preparing —. J. E. Engstad, Minneapolis, Minn. U.S. Pat. 1,231,143, June 26, 1917. Date of appl., Mar. 29, 1916.

CEREAL food products are prepared by subjecting the granular meal as it comes from the mill to dry steam under pressure at 235°—250° F. (113°—121° C.) for a sufficient time to break up the envelopes of the starch pellicles.—F. W. A.

XIXB.—WATER PURIFICATION ; SANITATION.

Hydrogen sulphide in water ; Determination of — at the source. G. Incze. Z. anal. Chem., 1917, 56, 308—311.

To 300 c.c. of the water is added 3 c.c. of a solution containing 85 grms. of silver nitrate and 200 grms.

of ammonium nitrate in a total bulk of 500 c.c. In the presence of the ammonium nitrate no silver carbonate is deposited, the precipitate consisting of silver chloride and silver sulphide. The excess of silver is measured by allowing the precipitate to settle for an hour and then titrating 101 c.c. of the clear liquid with N/50 ammonium thiocyanate. By performing a parallel experiment with water from which the hydrogen sulphide has been expelled by boiling, the quantity of silver nitrate consumed by the chlorides present can be determined.—D. F. T.

Carbon dioxide in water ; Determination of —. J. Tillmans and O. Heublein. Z. Unters. Nahr. Genussm., 1917, 33, 289—304. J. Chem. Soc., 1917, 112, ii., 332.

FREE carbon dioxide and that present as bicarbonates in water cannot be estimated accurately by precipitation with barium hydroxide and titration of the excess of the latter after the barium carbonate has settled; the inaccuracy of this method is due to the occlusion of barium hydroxide in the precipitated carbonate. The method is applicable, however, to solutions of carbon dioxide and bicarbonates in distilled water provided that the whole mixture (liquid and precipitate) is titrated, using phenolphthalein as indicator; the presence of magnesium salt renders this modification useless in the case of many drinking waters. The free carbon dioxide in water may be estimated by adding 1 c.c. of 0·0375% phenolphthalein solution to 200 c.c. of the water contained in a stoppered flask and then titrating the solution with N/20 sodium hydroxide solution until a pink coloration is obtained which persists for five minutes. If, at the end of the titration, the solution contains more than 440 mgrms. of carbon dioxide in the form of bicarbonate, the estimation must be repeated after the sample has been diluted with water free from carbon dioxide. Winkler's method (this J., 1915, 1111) is considered to be untrustworthy.

Sewage purification at Worcester ; Activated sludge process of —. T. Caink. Assoc. Managers of Sewage Disposal, July 7, 1917. Engineering, 1917, 104, 49—51.

THE tank employed in the process has a capacity of 626,000 galls. It is divided into rectangular bays, of which twenty are devoted to aeration and eight to settling. The floor is formed on the ridge and furrow principle, and in the furrows are porous tiles through which air is delivered to the sewage. These diffusers are placed 5 ft. apart in the first bays of the tank receiving the raw sewage, and 10 ft. apart in the other bays. The air escapes at the surface, and the circulation of the sewage tends to be a forward one. The floors of the settling bays are in the form of inverted pyramids, in the apices of which are air lifts whereby the sludge is raised to a main conveying it back to the sewage inlet channel for re-treatment. Excess sludge is drawn off to a sand filter for drying and disposal. The purified effluent is decanted from the settling tank. The volume of sewage treated is 750,000 galls. per day with 8 hrs. aeration and 2½ hrs. settling, the tank being worked on the continuous flow principle. The total area of the diffusers is about a tenth of the area of the aeration bays, and the volume of air used is 0·8 cu. ft. per gall. of sewage. The sludge from the settling bays when drained contains 95% of water. The analyses of the sewage and the effluent are respectively as follow in parts per 100,000: Solids in suspension, 10·4, trace; solids in solution, 151, 143; sodium chloride, 68·3, 67·7; free ammonia, 2·0, 2·6; albuminoid ammonia, 0·57, 0·17; oxygen absorbed in 4 hrs., 2·1, 0·56; nitrites and nitrates, 0, 0; dissolved

oxygen absorbed in 5 days by the effluent, 0.63. The effluent showed no putrefaction in 5 days by the incubation test. The standard to which the effluent has to conform is that it shall be incapable of putrefaction and shall not contain more than 4 parts per 100,000 of suspended matter. This has been fulfilled in the case of the dry weather flow but not in the case of the wet weather flow. The author recommends several alterations in the tank, of which the most important is that it should be provided with an air-tight roof, so that the air would have to travel horizontally over the sewage under the roof before leaving the tank, thus imparting a horizontal motion to the surface layer of sewage.—J. H. J.

Rain-water; Dissolved oxygen in —. E. H. Richards. J. Agric. Sci., 1917, 8, 331—337.

DETERMINATIONS of the dissolved oxygen in the rain falling at Rothamsted in 1915 were made by Winkler's method. The rain, collected at temperatures below 15° C. was only slightly below full saturation, average 93%. At temperatures above 15° C. the degree of saturation was much less, average 85%.—J. H. J.

Bacteria of the coli-aerogenes family; Improved chemical methods for differentiating —. W. M. Clark and H. A. Lubs. J. Biol. Chem., 1917, 30, 209—234.

ACCORDING to the method of Keyes (J. Med. Research, 1909, 21, 69) the ratio of the volumes of the gases CO₂:H₂ liberated in the anaerobic fermentation of dextrose by bacteria of the coli-aerogenes group affords an excellent means for the differentiation of these organisms, the species being divided into those which furnish a low gas ratio (*B. coli* group) and those with a high ratio (*B. aerogenes* group). The "methyl red test" has been devised to arrive at a correlated classification without the tedious gas analysis. This test is based on a differential production of acidity in the region of p_H=5.0 by the two groups of bacteria provided the quantity of dextrose available be restricted within certain well-defined limits. A medium suitable for this differential test is composed of 0.5% of dextrose, 0.5% of dipotassium hydrogen phosphate, and 0.5% of Witte's peptone. In view of the scarcity of Witte's peptone a revised formula has been worked out containing per litre 1 gm. of anhydrous disodium hydrogen phosphate, 2 grms. of potassium hydrogen phthalate, 1 gm. of aspartic acid, and 4 grms. of dextrose. The details to be attended to in performing the culture-tests are described and a satisfactory concordance between the methyl red test and the gas ratio test is recorded. Cultures showing low gas ratios turn the indicator red, while cultures with high gas ratios give yellow. The former type of bacteria occur in faeces and the latter in grain. The revised synthetic medium is also well adapted for carrying out the Voges-Proskauer colour reaction, but it is necessary to add some alkaline solution of casein to complete the development of the colour. This test affords a third means of differentiating the two types of bacteria and, although it is not always sharp and definite, perfect correlation with the gas ratio and methyl red tests is established.—J. F. B.

Benzene derivatives; Toxicity of various — to insects. W. Moore. J. Agric. Res., 1917, 9, 371—380.

ALL the benzene derivatives tested were more toxic to flies, molecule for molecule, than carbon disulphide. Physical characters such as the b. pt. and vapour pressure had a greater influence

than the chemical composition upon the toxicity of the compounds. Up to 250° C. the toxicity of the compounds increases with the b. pt., but in the case of compounds boiling above that temperature too little of the substance evaporates at the ordinary temperature to be effective. Lipoids are very soluble in benzene derivatives of low b. pt., but only sparingly soluble in those of high b. pt., so that there may be a relationship between the solvent action of the substances upon lipoids and their toxicity to insects. Compounds of low b. pt., such as xylene, chlorobenzene, and bromobenzene, will penetrate grain better than those of higher b. pt., and although less toxic, will probably be preferable for the fumigation of grain. For the fumigation of animals a compound of high b. pt. is necessary, and salicylic aldehyde is probably the best.—C. A. M.

Muscicides and other fly-destroying agencies; Experimental studies with —. E. B. Phelps and A. F. Stevenson. Hygienic Lab., Bull. No. 108. U.S.A. Public Health Service, Dec., 1916, pp. 37.

THE relative toxic action of solutions of various substances upon flies was determined, a N/1000 solution of sodium arsenite being taken as the standard basis for the comparison. It was found that quassia syrup and potassium bichromate were of little value, but that formaldehyde in 0.5 to 1% solution was a more efficient muscicide than the arsenite solution. Sodium salicylate in 1% solution, was almost equal to formaldehyde as a toxic agent, and was somewhat superior to solutions prepared from commercial fly-papers. Under the experimental conditions either of these solutions was much more effective than any sticky preparation.—C. A. M.

PATENTS.

Sterilised liquids; Apparatus for the production and aseptic storing of —. Sanitätsgesellschaft M. Schaerer A.-G., Bern-Wabern, Assignees of E. L. Hug, Bern, Switzerland. Eng. Pat. 100,744, June 19, 1916. (Appl. No. 8638 of 1916.) Under Int. Conv., June 19, 1915.

THE apparatus consists of a boiler surrounded by a casing open at the bottom. The cover of the boiler is bolted on and carries a central hollow pillar with a screw-on top and two side arms. One arm is connected to a bacteriological air filter; the other may be connected on the inside by a screw-down valve either to the air space in the boiler or to a vertical pipe leading down nearly to the bottom of the boiler, and on the outside to a pressure gauge and draw-off cock. When the boiler has to be charged the top of the hollow pillar is removed and the liquid to be sterilised is poured in; the top is screwed on again and heat applied either externally at the bottom or internally by a low-pressure steam coil. During the heating, the air space in the boiler is placed in communication with the two side arms, and the escaping steam sterilises the two arms and connections. When sterilisation is completed, the draw-off cock is closed, the draw-off arm placed in connection with the vertical pipe leading to the liquid, and the whole allowed to become cold. Air or other gas is then pumped through a cooling coil and the air filter into the boiler. The desired pressure being reached, the valve on the air pipe is closed. When it is desired to withdraw some of the liquid,

the draw-off cock is opened, and the air pressure inside forces the liquid up the vertical pipe and through the side arm. The apparatus is specially suited for the storage of physiological and surgical solutions.—J. H. J.

Distilling and evaporating [water]; Method of and apparatus for —. J. S. Forbes, Philadelphia. U.S. Pat. 1,232,269, July 3, 1917. Date of appl., Oct. 10, 1913.

HEATED water from the discharge pipe of a condenser is submitted in a finely-divided form to a vacuum or heated by the exhaust steam of an engine obtained at the beginning of the exhaust; a portion is vaporised, the unevaporated portion being removed by the incoming body of water, and the vapour is condensed.—J. H. J.

[Water] still. G. W. Crispell, Albany, N.Y. U.S. Pat. 1,231,857, July 3, 1917. Date of appl., Sep. 29, 1916.

The raw water is contained in an air-tight vessel, the bottom of which is connected by a horizontal narrow-bore pipe with the bottom of the still, which has a greater diameter than the raw water vessel. Another rather wider pipe connects the top of the raw water vessel with the lower part of the still, which is a vessel of conical shape, the neck of the cone being surrounded by a condensing chamber surmounted by a cold water vessel.—J. H. J.

Water-softeners; *Chemical-feeding device for* —. C. A. Cartwright, Chicago, Ill. U.S. Pat. 1,231,128, June 26, 1917. Date of appl., Mar. 13, 1915.

A CONTAINER for chemicals is connected by a conduit to a receiver, to which also is connected the water supply conduit. A motor is placed in the water supply conduit and is operated by the flow of water. The motor operates an air pump which delivers air to the chemical container, and also operates a water pump which delivers into the container and has an injector relation with the chemical supply conduit.—J. H. J.

Trichloride of iodine; Method for preservation of solutions of — for purifying contaminated water. U. Corbelli and E. Antolini, Rome. U.S. Pat. 1,231,853, July 3, 1917. Date of appl., Nov. 7, 1916.

A CONCENTRATED solution of iodine trichloride is saturated, or preferably supersaturated, with chlorine at a low temperature, and the product is immediately put into small tubes which are hermetically sealed at the same low temperature.—J. H. J.

Cake for insecticidal and fungicidal purposes; Soluble — and composition therefor. F. D. Houghton, Worcester, Mass. U.S. Pat. 1,231,741, July 3, 1917. Date of appl., Oct. 6, 1915.

LIME is slaked with hot water, flowers of sulphur being added during the slaking process; caustic soda is then added and the mixture boiled and stirred until the particles of sulphur disappear, when it is poured into moulds and allowed to set. The cakes are capable of retaining their shape and composition in the air, and are soluble in water; they contain about 22 % of lime and 22 % of sulphur.—J. H. J.

Insecticide. J. B. Barrett, Annapolis Royal, Nova Scotia. U.S. Pat. 1,230,648, June 19, 1917. Date of appl., Aug. 4, 1916.

The insecticide consists of naphthalene, 90 %

naphthalic acid, 8 %; and phenol, 2 %, mixed with an inactive agent as a filler. When exposed to the atmosphere a vapour is evolved and a "mineral oil" is liberated which coats the particles of the active agents and prevents too rapid an evolution of the vapour.—J. H. J.

Disinfectant. H. Bechhold, Frankfurt, Assignor to Chem. Fabr. Ladenburg Ges., Ladenburg, Germany. U.S. Pat. 1,232,187, July 3, 1917. Date of appl., Dec. 28, 1909.

SEE Eng. Pat. 25,472 of 1909; this J., 1910, 975. The halogenated β -naphthol derivative is specified to contain not less than three nor more than four halogen atoms per molecule.

Process for eliminating carbonate hardness from [brewing] waters. Ger. Pat. 297,873. See XVIII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Quinine bisulphate; Decomposition of —. B. F. Howard and O. Chick. Brit. Pharm. Conf., 1917. Chemist and Druggist, 1917, 89, 612.

THE conditions have been ascertained under which quinine bisulphate is converted into quinicine or quinotoxin. Quinine bisulphate (containing $7H_2O$) decomposes to the extent of 0.25 % at 60° C., while if previously exsiccated at 35°–40° C., no decomposition at 60° C. takes place. The addition of small quantities of water (e.g., half its weight), at any dangerous temperature, increases the decomposition, while larger quantities of water retard it. The limiting temperature at which quinine bisulphate, heated alone or in very strong solution for 24 hours, first decomposes is 60° C. At 90° C., 50 % decomposes in 24 hours, and 75 % in 48 hours. In an open vessel, the decomposition is only 17 % in 24 hours, owing to exsiccation. Melting the hydrated salt probably always causes decomposition. The formation of a bright yellow melt, giving a highly coloured, very refractive solution, is a certain indication of decomposition. The authors suggest the use of the bihydrochloride or the bihydrobromide for solutions requiring sterilisation by heat.—F. Sp.

Extractum Cinchonæ Liquidum, B.P. O. Chick. Brit. Pharm. Conf., 1917. Chemist and Druggist, 1917, 89, 612.

PAUL'S statement that only about 20 % of the total alkaloids can be obtained from red cinchona bark by macerating with dilute hydrochloric acid, is confirmed. The finished extract may contain more glycerin than the authors of the B.P. process intended. It is therefore better to add a definite amount of glycerin to the extract when standardising it, particularly as glycerin has no solvent action on the alkaloids of the bark. The gummy substance often deposited on evaporation of the extract appears to consist of quinovic acid and cinchona red, probably produced from quinovin and cinchotannin by hydrolysis. The standardisation test in B.P. 1898 sometimes causes trouble owing to the formation of a mucilage when the extract is made alkaline with caustic potash and extracted with benzolated amyl alcohol. The B.P. 1911 therefore replaces the aqueous caustic potash with a solution of caustic potash in 90 % spirit; this, however, gives inaccurate results, because

about 4% of the total alkaloids is left in the rejected caustic liquor, and about 4% passes, with amyl alcohol, into the wash waters. The author therefore prefers the 1898 test, and states that there is little trouble with matelage formation if the solvents are used hot and thorough shaking is given.—F. Sp.

Alkaloids; Microchemical precipitation of — with zinc chloride-iodine solution. O. Tunmann. Apoth.-Zeit., 1917, 62, 76—78. J. Chem. Soc., 1917, 112, ii., 345—346.

THE results described were obtained with more or less impure alkaloid residues, such as are prepared by the Stas-Otto method. The reagent does not yield crystalline products with arecoline, brucine, cocaine, quinine, cinchonine, coniine, colchicine, narceine, nicotine, eserine, or veratrine. On the other hand, it is well adapted for the identification of strychnine, sparteine, the opium alkaloids, morphine, papaverine, cryptopine, and codeine, as well as atropine and hyoscyamine. With atropine, brown or dark red to blackish-red crystals, mostly rhombs, are immediately produced, which, at the commencement of the reaction, vary greatly in size. All the crystals shine but little between crossed Nicols, and do not exhibit pleochroism. The crystal crosses, consisting of four rhombs, are particularly characteristic. The limit of sensitiveness is 10—20 μ g. The iodide crystals of hyoscyamine shine feebly in polarised light, they are very small (4—8 μ), almost black, and without pleochroism. The platelets have generally a far less regular circumference than the atropine crystals. Limit of sensitiveness, 10 μ g. Zinc chloride-iodine yields crystals even with very impure morphine preparations; initially, fine, pale brown needles are formed, which after ten to twenty minutes unite to sheaves, and are then transformed into prismatic crystals with direct extinction. The latter are brown, the larger ones being nearly black; they do not exhibit pleochroism and scarcely shine between crossed Nicols. Limit of sensitiveness, 5 μ g. Papaverine and cryptopine give long, dull red, yellowish-red, or greenish-red crystals from 2—3 μ diameter, which have direct extinction, show red to blue polarisation colours, and exhibit pleochroism. The latter phenomenon yields an excellent method of differentiating between the three opium alkaloids considered here. Limit of sensitiveness, about 10 μ g. In addition to the crystals described above, deep red drops are also formed which, after some hours, pass into deep red aggregates; this points to the presence of a second alkaloid (? cryptopine) or papaverine. Codeine behaves very differently. A powdery precipitate is first obtained, which when warmed deposits larger and smaller particles, from which very slender, generally curved, pale brown crystals grow. The limit of sensitiveness is about 40 μ g. Excess of the reagent is to be avoided. Sparteine is preferably converted into the sulphate, and this gives with the reagent fine, yellowish-red crystal threads, which form sheaves and brushes at their ends. When warmed, coarser prismatic crystals appear after about thirty minutes, and in addition, when further heated, yellow aggregates are occasionally obtained. All the crystals shine strongly in polarised light, have extinction parallel to the long axis, and show very marked pleochroism. When warmed with zinc chloride-iodine, strychnine gives brownish-red or blackish-red spheres or aggregates which attain a diameter of 50 μ , and lie separately or are grouped in chains. They glow red between crossed Nicols, but do not exhibit pleochroism. Limit of sensitiveness, 15 μ g. Unless specific mention to the contrary is made, the above data refer to the crystals which are produced after one to two hours' action.

Atropine and related mydriatic alkaloids; Detection of —. R. Eder. Schweiz. Apoth. Zeit., 54, 501—504, 517—520, 534—537, 544—548, 560—563, 609—612, 621—624, 657—661, 669—670, 685—687, 717—719. J. Chem. Soc., 1917, 112, ii., 346—347.

THE methods employed in the detection of atropine and related mydriatic alkaloids are critically reviewed, and two new reagents for the detection and differentiation of the more important of these bases are described. Bromine water and bromine-potassium bromide are recommended as reagents for the microchemical detection of the *Solanaceae* bases. A drop of the solution of the alkaloid in N/2-sulphuric acid is brought on to an object-glass, and a drop of the reagent is added; after a short time, with small magnification, a fine turbidity appears, followed more or less rapidly by the formation of minute crystals, which present the appearance of fine, pale yellow needles. The crystals rapidly increase and sink to the bottom of the liquid, which gradually becomes clear. In the inner portions, individual needles frequently grow to stout, yellow rods; at the edge of the drop, on the other hand, the needles speedily begin to disappear, whilst the solution becomes colourless. The crystals also disappear more or less rapidly from the inner portions, and the solution becomes colourless as the bromine evaporates. The shape of the crystals is best studied with a 180—250 times magnification, and the solution should be protected with a cover-glass, thus rendering the crystals more stable. The reaction of atropine towards bromine water has the advantage over other atropine reactions that it can be repeated as often as desired with one and the same specimen. When the solution has become clear and colourless, the characteristic precipitate can be again obtained by renewed application of bromine water. The reaction is distinctly obtained at dilution of 1 in 3000. The macrochemical behaviour of atropine in N/2-sulphuric acid solution towards bromine-potassium bromide (Br 1 gm., KBr 2 gms., water 20 gms.) is similar to its action on bromine water, but the reaction is considerably more sensitive.

Hyoscyamine reacts with bromine water in much the same manner as atropine. The yellow, cloudy precipitate rapidly becomes crystalline, and disappears as the bromine evaporates. The highly magnified crystals, however, have a very variable character. For this reason, bromine water is a less suitable reagent for the detection of the alkaloid than bromine-potassium bromide. The limit of sensitiveness of the latter is reached at a dilution of about 1 in 5000. By means of the reaction, atropine can be detected in the presence of hyoscyamine in a mixture of the alkaloids.

The macrochemical behaviour of homatropine and scopolamine towards bromine water and bromine-potassium bromide exactly resembles that of atropine. The yellow precipitate obtained from scopolamine with bromine water appears under the microscope to consist exclusively of amorphous drops, crystallisation only occurring infrequently and at isolated points. Similar results are observed with bromine-potassium bromide. The precipitate of homatropine with bromine water is at first amorphous, but rapidly becomes crystalline, whilst that with bromine-potassium bromide closely resembles the precipitate with atropine.

With the exception of caffeine, the remaining alkaloids, which yield yellow or otherwise coloured precipitates with bromine water or bromine-potassium bromide, give only amorphous deposits. The crystalline compound from caffeine may be useful in the detection of the latter. Iodine-potassium iodide gives reddish-brown, crystalline precipitates with atropine, hyoscyamine, and homatropine, which are less characteristic than the

bromine-potassium bromide compounds. With scopolamine, as with most other alkaloids, the precipitates are amorphous.

There is no single reaction on which dependence can be placed for the detection of atropine and related alkaloids. Of the many reactions which have been previously proposed, only a few are suited to the practical detection of the bases. The following are to be recommended: physiological examination, Vitali's reaction, behaviour towards concentrated sulphuric acid in the cold (no coloration) and in the warm (odour after addition of water). Of colour reactions, with the exception of the negative tests with Froehde's and Erdmann's reagents, only Wasicky's reaction with dimethylaminobenzaldehyde and, possibly, Arnold's reaction need to be considered. Among microchemical methods and reactions, micro-sublimation, the iodine-atropine salt, and, particularly, the reactions with bromine water and bromine-potassium bromide, give good results. In the presence of other alkaloids which give amorphous precipitates with the bromine reagents a separation is necessary which can frequently be effected by micro-sublimation.

Solanine. A. Heiduschka and H. Sieger. Arch. Pharm., 1917, 258, 18—44. J. Chem. Soc., 1917, 112, i., 407—408.

ON account of the tendency of solanine to decomposition and to sublimation, the m. pt. of the substance is rather indefinite; a more valuable characteristic is the optical activity in 2% hydrochloric acid, $[\alpha]_D^{20} = -42.16^\circ$. The composition of the pure substance isolated from potato shoots agreed best with a formula $C_{22}H_{39}O_{16}N$. The hydrochloride ($C_{22}H_{39}O_{16}N, HCl$) was obtained in a crystalline condition, m. pt. $212^\circ C$. (decomp.), after sintering at $177^\circ C$. Hydrolysis of solanine is best effected with 2% hydrochloric acid solution; the resulting solanidine, m. pt. $207^\circ C$., judged by its composition and molecular weight in phenol, possesses the formula $C_{24}H_{45}O_4N$. Each molecule of solanine gives one molecule each of solanidine, dextrose, galactose, and rhamnose. Dehydration of solanidine by concentrated hydrochloric acid or other agents yielded not only solanine, $C_{24}H_{45}ON$, but also a base intermediate between this and solanidine, probably derived from solanidine by the elimination of semi-molecular proportion of water. Solanine forms an additive compound with phytosterol, and, when heated, evolves vapours which reddens a pine shaving. An examination of solanine from the *Palo Natri* of Chile showed this substance to be identical with the product from potatoes.

Medicinal substances; Preliminary work at the Soukhom Experiment Station, Caucasus, on the extraction of — from local plants (eucalyptus, wild mint, camphor, castor oil, etc.). M. N. Kozlov. Agric. of the Coast of the Black Sea, Soukhom (Russian), 1916, 13, 20—39. Bull. Agric. Intell., 1916, 7, 1621—1622.

NUMEROUS observations made by the Acclimatisation Section of the Soukhom Station have shown that it is quite practicable to cultivate species of eucalyptus, rich in essential oils, on the Batumi coast. The first attempt to extract these oils was successfully made in 1899—1900, but the work was not continued. The quantity of essential oils in the eucalyptus is greatest in the spring and early summer. Beklemichev extracted from *E. globulus*, for example, 0.8% in September, 0.7% in December, and 0.9% in March. In September the author extracted 0.6% from *E. viminalis*, 1.8% from *E. pulverulenta*, and 1.1% from the fresh leaves of *E. globulus*. The drying of the leaves reduces the cost of distillation without loss of oil. *E. globulus*,

E. maideni, and *E. pulverulenta*, all of which grow well on the Batumi Coast, yield very similar oils containing over 40% of eucalyptol. *E. maideni* yields a greater total leafage, of higher oil-content, than *E. globulus*. It is estimated that, assuming capital for laying out plantations at £19 per acre, and annual expenditure about £8 per acre, a return of £19—£22 per acre may be expected, representing interest at the rate of 13—30% on a capital of £2600—£3000 laid out on 25—30 acres of land and on the building of a factory. Investigations on the wild mint (*Mentha pulegium*) and castor oil plants, gave satisfactory results; 0.4% of essential oil was obtained from fresh mint and 1.09% from the air-dried material, whilst the proportion of oil in castor oil seeds reached 49.5%. From the fresh leaves of a tree of *Cinnamomum camphora* Nees, about 20 years old, 0.9% of raw camphor was obtained, consisting of 22.6% of oil of camphor and the rest camphor. With large branches 1.5—2 inches in diameter, negative results were obtained.—J. H. L.

Ninhydrin reaction with glycerol, etc.; The alleged —. V. J. Harding. J. Biol. Chem., 1917, 30, 205—208.

THE colouring matter produced in the ninhydrin reaction with amino-acids has been shown by Ruhemann (Chem. Soc. Trans., 1911, 99, 1486) to be the ammonium salt of diketohydrindylidene-diketohydrindamine. The same reaction is given with ammonium salts, provided the concentration is sufficient; the reaction with amines depends on the concentration of the amine and its constitution; with amides the results are negative. Halle, Loewenstein, and Pribram (Biochem. Zeits., 1913, 55, 357) have stated that glycerol gives a ninhydrin reaction, and the same statement has been made concerning other aldehydes, ketones, and alcohols, in all cases, however, only at high concentrations. The author has found that the reaction with glycerol varies with the purity of the sample and that it probably depends on the presence of a nitrogenous impurity in the glycerol, most likely an ammonium salt, which, owing to its small proportion, only reacts at a high temperature when the reaction is assisted by the reducing action of the glycerol. On the other hand, the reaction with amino-acids takes place in presence of small quantities of these substances at a moderate temperature and is not influenced by the action of alkalis and the presence of oxygen.—J. F. B.

Ammonium thiocyanate with formaldehyde; Condensation product of —. Schmerda. Z. angew. Chem., 1917, 30, 176.

AMMONIUM thiocyanate combines with formaldehyde in concentrated aqueous solution in equimolecular proportions without production of carbon dioxide. The condensation product can combine with further quantities of formaldehyde forming products which readily part with formaldehyde. The products were amorphous yellow compounds without definite melting-point, and were practically insoluble except in strong acids and strong alkalis, which decomposed them into their components. It is believed that the products may find some use for pharmaceutical purposes, for if placed on wounds they induce the growth of a protective skin.—J. B. C. K.

Odour and constitution; The relation between —. H. J. Prins. Perf. and Essent. Oil Rec., 1917, 8, 222—223.

MAJEWSKI's theory (Ber., 33, 3401) that the

odour of substances is due to the presence of "osmophoric" groups was modified by Marchand (Deuts. Parf. Z., 1915, 232, 243, 287), who concluded that the non-osmophoric part of the molecule determined the class of the odour, while its shade or tinge depended on the osmophoric groups. It is more correct to regard all groups as osmophoric, but different in strength. Thus the odour of benzene derivatives is similar because the substituting groups cannot entirely overcome the osmophoric influence of the benzene molecule. On the other hand, the different odours of octyl alcohol, octyl aldehyde, and octylic acid demonstrate the weak osmophoric influence of the aliphatic hydrocarbons. Chemically homologous substances have similar odours, e.g., octyl, nonyl, and decyl aldehydes, and octyl, nonyl, and decyl alcohols. If an alteration in the hydrocarbon part of an aromatic substance has a great influence on the chemical character of the strongest osmophoric group, there will be a considerable change in the odour (cf. the difference in odour between lauraldehyde and methyl-nonylacetic aldehyde). Double bonds in the neighbourhood of an alcoholic, aldehydic, or carboxylic group have a strong influence on odour (cf. decyl aldehyde with undecylene aldehyde, nonyl aldehyde with 2,3-nonylene aldehyde, citronellal with citral, α -ionone with β -ionone). Of two changes in the constitution of a compound, the odour will be most affected by that change having the strongest influence on the most powerful osmophoric group. The influence of formic acid preponderates over that of alcohols in the formic esters, the preponderance being least in the formates of strongly osmophoric alcohols such as borneol and menthol.—F. Sp.

Protective colloids. VIII. Tubera salep as protective colloid. Colloidal silver, arsenic, and antimony. A. Guthier and N. Kräutle. Kolloid Zeits., 1917, 20, 83—101, 123—127, 186—198. J. Chem. Soc., 1917, 112, ii., 244, 298—299.

THE preparation of colloidal solutions of silver by the action of sodium hydrosulphite in presence of extract of *Tubera salep* as protective colloid is described. The silver sols thus obtained are of great stability, and this stability does not seem to be affected by the fact that the colour of the solutions in transmitted light varies with the conditions.

The protective action of extracts of various plant colloids on colloidal arsenic, prepared by the reducing action of sodium hydrosulphite on lightly acidified solutions of arsenious oxide, is very marked, and it has been found possible to obtain by evaporation solid colloids containing about 3% of arsenic which are completely soluble in water. The protected solutions of colloidal arsenic are not appreciably influenced by the addition of hydrochloric acid, sulphuric acid, sodium chloride, and barium chloride, whereas sodium hydroxide and sodium carbonate change the colour from dark brown to light yellow.

Colloidal solutions of antimony, prepared by the action of sodium hydrosulphite on a solution of potassium antimoniate acidified slightly by the addition of tartaric acid, are found to have their stability considerably increased in presence of the extract of *Tubera salep*. The dialysed solutions may be evaporated to give solid colloids containing about 10% of antimony which dissolve completely in water. The stability of the protected solutions is not affected by the addition of acids and neutral salts, but alkalinity reduces the stability to a large extent. In this respect, the behaviour of the colloidal antimony solutions resembles that of solutions of the protective colloid.

Stabilization of bromides. Rupp and Hollatz. See VII.

PATENTS.

Chlorinated hydrocarbons; Production of —. B. T. Brooks and D. F. Smith, Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,231,123, June 26, 1917. Date of appl., Dec. 10, 1915.

ETHYLENE and propylene are separated in approximate purity from oil gas by liquefaction and fractionation, and are chlorinated by passing them with chlorine into a liquid which dissolves both the chlorine and the hydrocarbons. The liquid employed contains dichlorinated ethylene hydrocarbons resulting from the reaction, the product of which is chiefly ethylene and propylene dichlorides.—F. Sp.

Arsenophosphorus compounds and process of making same; Organic —. A. Mouneyrat, Paris. U.S. Pat. 1,232,373, July 3, 1917. Date of appl., Feb. 16, 1915.

ARSENOPHOSPHORUS compounds are produced by treating aminophenylarsinic acid with phosphorus oxychloride. They form yellow powders soluble in dilute sodium carbonate solutions.—F. Sp.

Cinchona alkaloids and 2-phenylquinoline-4-carboxylic acid; Compounds of —. A. B. Davis, Indianapolis, Ind. Eng. Pat. 106,430, Nov. 27, 1916. (Appl. No. 16,995 of 1916).

A COMPOUND having antipyretic and antiphlogistic properties, and acting as a uric acid eliminant, is produced by adding a solution of a salt of quinine or other cinchona alkaloid to a solution of an alkali salt of 2-phenylquinoline-4-carboxylic acid.—F. Sp.

Apparatus for the production and aseptic storing of sterilised liquids. Eng. Pat. 100,744. See XI XB.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Cinematograph films and the like; Process for the quick drying of —. E. Planchat, Turin, Italy. U.S. Pat. 1,232,077, July 3, 1917. Date of appl., Nov. 18, 1915.

CINEMATOGRAPH film is dried by passing it downward through a column of mercury or of liquid amalgam of a height sufficient to squeeze out the greater part of the water. The film passes upward through a second column separated by a partition from the first, to avoid contact between the film and the expressed moisture.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

PATENTS.

Explosive composition and method of producing same. H. Hibbert, Pittsburgh, Pa. U.S. Pat. 1,231,351, June 26, 1917. Date of appl., Apr. 17, 1916.

AN explosive composition is produced by dissolving a carbohydrate in a mixture of 1,2-glycols containing ethylene-, propylene-, and butylene-glycols

and polyglycols, nitrating the resulting solution to produce a mixture of nitro-carbohydrate, nitrated 1,2-glycols, and nitrated polyglycols.

Picric acid: Recovering — from wash water.
H. A. Gardner, Washington, D.C. U.S. Pat.
1,231,009, June 26, 1917. Date of appl. Dec.
16, 1915.

PICRIC acid is recovered from wash water by adding sodium bisulphate in sufficient quantity to form a solution of high specific gravity in which picric acid is practically insoluble. It separates in flocculent form on the surface and is removed, and the wash water is decolorised by adding bleaching powder.—F. Sp.

XXIII.—ANALYSIS.

Gas density: Effusion method of determining —.
J. D. Edwards, U.S. Bureau of Standards.
Gas J., 1917, 139, 108.

A PRELIMINARY report on a study of the Bunsen effusion method of determining gas densities is given. Platinum-iridium alloy (85:15) is recommended as material for the plate containing the orifice. The results obtained depend on the initial pressure of the gas. Mercury is preferable to water as confining medium. With the former, the orifice may be fouled by the condensation of water on expansion. Either displacement or expansion forms of apparatus may be used. The latter require a smaller quantity of containing medium, an advantage when mercury is used. With careful standardisation and correcting factors the effusion method applied to gases of a similar general nature gives results correct to within 2%, but with a given size of orifice there is no effusion pressure at which correct results are obtainable with different gases, and the necessary corrections are too complicated to admit of use in the form of tables.—H. J. H.

Gases: Specific gravity balance for —. J. D. Edwards, U.S. Bureau of Standards, Technol. Paper No. 89, Feb. 23, 1917. 19 pages.

THE effusion method of determining the density of natural gas has proved unreliable in practice (see preceding abstract), and other methods have therefore been investigated. If the pressures on two gases are regulated so that both gases exert the same buoyant force on the same body, then the two pressures will be inversely proportional to the densities at normal pressures. An apparatus has been devised for comparing the pressures of gases under these conditions. It consists of a balance beam carrying a sealed hollow globe at one end, counterpoised by a weight on the other. The balance beam is pivoted on a support mounted inside a gas-tight chamber to which a mercury manometer is attached. In practice the case is first filled with dry air and the beam brought to its zero position by adjusting the pressure of the air. The air is then replaced by the gas, the density of which is to be measured, and the pressure adjusted until the beam is again brought to zero. Descriptions are given of the construction of several instruments, differing in sensitiveness and portability. The accuracy of the method is such that the results agree with those obtained by the weighing method to 0.2% except with gases which show considerable deviation from Boyle's law. By making allowance for their deviations, an agreement to 0.2% can be obtained in these cases

also. Advantage is claimed for the speed of operation and also because no preliminary calibration of the instrument is necessary.—H. J. H.

Methyl red as an indicator. F. Lehmann and G. Wolff. Arch. Pharm., 1917, 255, 113—119. J. Chem. Soc., 1917, 112, ii, 326—327.

METHYL red (*p* - dimethylaminoazobenzene-*o*-carboxylic acid) is more sensitive to hydroxyl ions than is methyl orange, and has about the same general value for the titration of bases of all strengths that phenolphthalein has for acids. It is also more sensitive than methyl orange towards hydrogen ions, and might therefore be of more extended use in acidimetry. Oxalic and picric acids can be titrated readily with it, and also alkali borates and cyanides. Sulphites do not give sharp end-points, and sulphides and carbonates give intermediate orange tones which should be ignored, the titration being continued until the final change to bright pink occurs. The change from red (acid) to yellow (alkaline) is as sharp as the change from yellow to red, and solutions standardised with the aid of phenolphthalein are found to be practically of the same normality when tested with methyl red. The best results are obtained with two or three drops of a 0.1% solution in about 100 c.c. of liquid.

Carbon dioxide and carbonates in solution: Determination of —. D. D. van Slyke. J. Biol. Chem., 1917, 30, 347—368.

A SIMPLE one-piece apparatus is described for the determination of carbon dioxide or carbonates in aqueous solutions. It was devised primarily for the analysis of 1 c.c. samples of blood plasma but is applicable to aqueous solutions generally and to the determination of dissolved gases other than carbon dioxide. The apparatus consists essentially of a 50 c.c. pipette with 3-way cocks at top and bottom and a scale on the upper stem graduated in 0.02 c.c. divisions. The bottom of the apparatus is connected with a mercury levelling bottle and the lower cock with a bulb into which the solution is drawn after the extraction of the carbon dioxide and with a passage for the release of the vacuum by admission of mercury. The upper 3-way cock communicates with a graduated funnel and a capillary tube. The pipette is filled with mercury, and the solution is introduced and acidified in the pipette, the total quantity of water being preferably 2.5 c.c. A Torricellian vacuum is produced by lowering the reservoir; the carbon dioxide is extracted from the water by shaking for half a minute in the evacuated chamber and the water is drawn out of the 50 c.c. chamber into the lower bulb. Mercury is then admitted through the by-pass and the volume of the gas is read in the finely graduated upper stem. The observed volume is corrected by the subtraction of the amount of air dissolved in the water (0.04—0.05 c.c. according to temperature) and the addition of the 4—5% of the total carbon dioxide which remains dissolved in the water; these corrections may be determined directly or calculated with a high degree of accuracy from known data. The operation is performed at the ordinary temperature in about 3 minutes and the results are accurate within 1% of the amount determined.—J. F. B.

Zinc: Volumetric methods for the determination of —. J. W. Springer. Z. angew. Chem., 1917, 30, 173—174.

THE author discusses the various volumetric methods for the determination of zinc that have been proposed and tried experimentally, and points out the effects produced by the presence of manganese and iron in most zinc ores upon

the accuracy of these methods. The method which has been found most useful in the author's laboratory is a modification of that proposed by L. Blum (*Z. anal. Chem.*, 1892, 60). The following is a description of the modified method:—2 to 5 grms. of the ore is heated in a covered beaker with 20–25 c.c. of concentrated hydrochloric acid until the hydrogen sulphide is driven off; 10–25 c.c. of nitric acid is now added and the heating is continued until complete solution is effected. The contents of the beaker are evaporated to dryness, and the evaporation is repeated after moistening the residue with hydrochloric acid. After expelling the last traces of nitric acid the residue is taken up with 20–50 c.c. of hydrochloric acid, and is diluted to 200 or 400 c.c. and boiled. Hydrogen sulphide is now passed through the hot solution until it cools, the mixture is made up to 250 or 500 c.c., well shaken, and filtered. 50 c.c. of the filtrate is treated with bromine water and heated until the solution has become clear, after which the iron and manganese are precipitated by adding 25 c.c. of ammonia solution and the liquid is again boiled. The zinc is now titrated with potassium ferrocyanide in this hot solution. It is important to keep the volume of the solution approximately the same as that used for the check-test, which is carried out with 0.25 grm. of chemically pure zinc, 4 to 5 c.c. of hydrochloric acid, and 20 c.c. of ammonia solution.—J. B. C. K.

Manganese; Use of the platinised glass anode in electrolytic determination of—. F. A. Gooch and M. Kobayashi. *Amer. J. Sci.*, 1917, 44, 53–56.

ATTEMPTS to deposit hydrated manganese dioxide electrolytically from manganous sulphate solution, using rotating platinum electrodes, as described in a previous paper (this J., 1917, 671), were unsuccessful owing to the superoxidation to permanganic acid. The use of deoxidising agents to neutralise this led to unsatisfactory results. Successful results were obtained, however, by using a modified form of the rotating electrode of platinised glass described by Gooch and Burdick (*Amer. J. Sci.*, 1912, 34, 107). The anode used was made by heating, to a temperature sufficient to volatilise glycerin, a tube of lead glass shaped like a test tube, painting upon it a viscous emulsion of dry chloroplatinic acid in glycerin, and burning the film of deposited platinum into the glass by the softening point of the latter. The manganese was completely deposited from electrodes containing about 0.1 grm. Mn (as sulphate) in 100 c.c., in presence of acetic acid; the time required was 2½ hrs. when chrome alum was added to the electrolyte and 3½ to 4 hrs. with alcohol and ammonium sulphate.—T. H. B.

Ammonium molybdate; Recovery of— from the filtrates obtained in the estimation of phosphoric acid. H. Kinder. *Stahl u. Eisen*, 1916, 36, 1094. *J. Chem. Soc.*, 1917, 112, ii., 321.

THE following method is stated to be more simple than that described by Friedrich (this J., 1916, 5). The molybdic acid is precipitated by adding lithium phosphate to the solution, and the yellow precipitate is washed by decantation with 0.1% lithium sulphate solution until free from soluble phosphate and iron salts. The precipitate is then dried; each 325 grms. of it is dissolved in 1100 c.c. of ammonia (sp. gr. 0.96), the solution is treated with a mixture of 30 grms. of magnesium chloride and 130 grms. of ammonium chloride dissolved in water to make 100 c.c.; the precipitate is separated by filtration, and each 420 c.c. of filtrate is mixed with 1200 c.c. of nitric acid (sp. gr. 1.2).

The blue molybdic acid residues obtained in the gravimetric estimation of phosphoric acid may be treated in a similar way (dissolved in ammonia, acidified with nitric acid, precipitated with sodium phosphate, etc.).

PATENTS.

Radiation-pyrometer. C. B. Thwing, Assignor to Thwing Instrument Co., Philadelphia. U.S. Pat. 1,232,408, July 3, 1917. Date of appl., May 4, 1914.

A HOLLOW refractory cylinder is mounted in the wall of a furnace so that its closed end projects within the furnace. A thermocouple is mounted in a casing at the opposite end of the cylinder so that its hot junction does not project beyond the furnace wall, and is acted on by heat radiated from the heated end of the cylinder. The cold junction of the thermocouple is contained within a cap closing the outer end of the refractory cylinder.
—W. F. F.

Flash-point tester. F. Von Bichowsky, Berkeley, Cal. U.S. Pat. 1,232,413, July 3, 1917. Date of appl., July 25, 1914.

OIL or other inflammable liquid is heated in a container and automatically stirred. Sparks are periodically passed above the surface of the heating oil and means are provided for registering the temperature at which the vapour ignites. The container is provided with vents having closing members which are normally held open by a string against the action of a closing weight. When the vapour ignites, the string is burnt and the weight allowed to fall, thus closing the vents and extinguishing the flame.—W. F. F.

Methane detector. C. M. Means, Assignor to W. A. McCutcheon, Pittsburgh. U.S. Pat. 1,231,045, June 26, 1917. Date of appl., Jan. 27, 1916.

GAS to be tested is passed through a casing containing two wires connected in series to a source of electric current, one wire being catalytically active and the other inactive. The amount of methane is estimated by a comparison of the relative luminosities of the two wires. The catalytic wire has a positive resistance coefficient, the presence of methane thus reducing the current flowing in the second wire, the temperature of which is not affected by the gas. Means may be provided for short-circuiting the second wire so as to cause increased current to flow in the catalytic wire to restore its catalytic properties in the event of deterioration.—W. F. F.

ROYAL ONTARIO NICKEL COMMISSION. REPORT AND APPENDIX. 1917. A. T. Wilgress, Toronto. XLVIII. +765 pages. 9½×6½ in.

THE introductory portion of this volume contains the text of the Commission of September 9th, 1915, and of the Supplementary Commission of March 19th, 1917, and also the summary and conclusions, of which an abstract has already appeared (this Journal, 1917, 490).

The Report is divided into chapters as follows:— I. Agitation for home refining of nickel. II. Historical sketch of nickel discoveries. III. The operating nickel companies. IV. Nickel deposits of the world. V. Properties and uses of nickel and its compounds. VI. Non-ferrous nickel alloys. VII. Nickel steel and other nickel alloys containing iron. VIII. Smelting nickel ores. IX. Refining processes. X. Recovery of metals of the platinum group. XI. Recovery and utilisation of sulphur. XII. Statistics. XIII. Taxation of mines and mining industries. XIV. Bibliography of nickel. The Appendix contains the Minutes of Evidence, memoranda, and papers presented to the Commission. The volume is fully illustrated and forms a most valuable addition to the literature of the subject.

INDUSTRIAL AND MANUFACTURING CHEMISTRY. PART II. INORGANIC. Vol. II. By G. MARTIN. Crosby Lockwood and Son, 7, Stationers' Hall Court, London, E.C. 482 pages, 9½×6½ in. Price 25s.

THE sections into which this volume is divided, and their authors' names, are as follows:—LII. Disinfectants and antiseptics (G. Martin). LIII. Insecticides, fungicides, and sheep-dips (G. Martin). LIV. Artificial manures (A. S. Carlos). LV. The industry of aluminium compounds (G. Martin). LVI. The artificial zeolite or permutite industry (G. Martin). LVII. The artificial gem industry (G. Martin). LVIII. Aluminium-thermics. "Thermit" and its applications (H. S. Redgrove). LIX. The calcareous cements industry (E. A. Dancaster). LX. Sorrel cement (J. Shelton). LXI. Artificial stone (J. Shelton). LXII. Sodium silicate, water-glass, soluble glass (J. Shelton). LXIII. Lutes and miscellaneous cements (G. Martin). LXIV. Clays and allied materials (A. B. Searle). LXV. Pottery (A. B. SPECIAL NOTICE TO MEMBERS.

At a Special General Meeting of the Society held on *Wednesday, August 15th, 1917*, the resolution to increase the yearly subscription and the amounts payable for life composition, which was adopted at the Annual General Meeting at Birmingham on July 18th last, was unanimously confirmed.

It is therefore hereby intimated that on and after 1st January, 1918, the yearly subscription will be £1 10s., and the sums payable under By-law 11 for life composition will each be increased by £5.

J. P. LONGSTAFF.

Broadway Chambers, *General Secretary.*
Westminster, S.W. 1.

PROHIBITED EXPORTS.

ORDER-IN-COUNCIL, 28TH AUGUST, 1917.

The following headings are deleted* :—(B) Beeswax; (A) Saccharin; (A) Malt extract, and preparations containing malt extract; (A) Malt sugar; (A) Quercitron bark extract; (A) Tanning extracts and substances for use in tanning, including cutch; (C) Vanillin; (A) Wire, iron; (A) Wire, steel.

The following headings are added :—(A) Beeswax; (C) Dyes, vegetable, and dyestuffs and their extracts used in the preparation of vegetable dyes, and articles containing such dyes, dyestuffs and extracts, not otherwise prohibited; (A) Saccharin, and articles, mixtures, and preparations containing saccharin; (A) Cutch and extracts thereof; (A) Gall nuts and extracts thereof; (A) Gambier and extracts thereof; marjoram leaves; (A) Invert sugar, and articles, mixtures and preparations containing invert sugar; (A) Malt sugar (maltose), and articles and preparations containing malt sugar; (C) Pyrites cinders; (A) Quercitron bark and extracts thereof; (A) Tanning extracts and substances for use in tanning; (C) Thyme leaves; (B) Vanadium ore; (C) Vanillin, vanilla and vanilla pods; (A) Wire, iron, and articles wholly manufactured thereof; (A) Wire, steel, and articles wholly manufactured thereof.

TRINITROTOLUOL.

ORDER IN COUNCIL, AUGUST 22ND, 1917.

On Order in Council, dated Aug. 22nd, revokes the Order made on June 11th, 1910, whereby trinitrotoluol was exempted from certain of the provisions of the Explosives Act, 1875.

STEEL SCRAP, WROUGHT IRON SCRAP, AND TINPLATES AND TERNEPLATES.

The Minister of Munitions has issued an Order dated Aug. 28th, according to which steel scrap is classed as "War material"; maximum prices are fixed for dealings in such material. On the same date certain modifications of the general permit relating to dealings in wrought iron scrap came into effect.

* The prohibition of exports is as follows :—

Goods marked (A), to all destinations;
Goods marked (B), to all ports and destinations abroad other than ports and destinations in British Possessions and Protectorates;

Goods marked (C), to all destinations in foreign countries in Europe and on the Mediterranean and Black Seas, other than France and French Possessions, Russia, Italy and Italian Possessions, Spain and Portugal, and to all ports in any such foreign countries, and to all Russian Baltic ports.

A Ministry of Munitions Order, dated Aug. 24th, regulates dealings in tinplates and terneplates and fixes maximum prices for these.

The above Orders and notices are printed in full in the "Board of Trade Journal" for August 30th.

BLAST-FURNACE DUST.

An Order, dated 7th August, 1917, has been issued by the Ministry of Munitions to the effect that :—

1. No person shall buy, sell, deal in or dispose of any blast-furnace dust except under and in accordance with the terms of a licence issued on behalf of the Minister of Munitions by the Controller of Potash Production.

2. No person shall treat any such dust so as to extract any component part thereof except under and in accordance with the terms of a licence issued as aforesaid.

3. All persons producing or in possession of blast-furnace dust shall make returns in regard to rate of production, stocks, purchases, sales, dealings, or other matters relating to blast-furnace dust in such form and at such times as may be required by the said Controller.

4. Samples of any blast-furnace dust produced by or in the possession of any person shall be furnished to the said Controller by such person in such form and quantity and at such times as the said Controller may prescribe. Such samples shall be taken in such manner as the said Controller or his authorised representative may prescribe.

5. For the purpose of this Order blast-furnace dust shall mean dust deposited or otherwise derived from the gases of any furnace used for treating ores for the production of iron or any of its alloys.

6. All applications in reference to the above Order should be made to the Controller of Potash Production, Ministry of Munitions, 117, Piccadilly, W.1.

BASIC SLAG.

A Notice, dated 1st August, 1917, has been issued by the Food Production Department, relating to basic slag. It is stated that the slags which are now available for grinding have a low phosphatic content, and the supply of high-grade slag is therefore much less than was formerly the case. All the suitable slag available is being ground, and the total tonnage is fully equal to what it was before the War. As no export is now allowed, the quantity available for home consumption is much larger, though it is still below the demand. Arrangements are being made in certain cases to grind a low-grade slag, which has not hitherto been used as a manure. It can be economically used on land within a moderate distance of the works. The Food Production Department, in conjunction with the Ministry of Munitions, has come to an arrangement with makers in regard to the maximum prices to be charged by them, and the Notice in question enumerates these prices.

DEALINGS IN CHROME ORE.

The Minister of Munitions has made an Order, dated 31st August, ordering that as from that date, until further notice, no person shall purchase

or take delivery of chrome ore of any grade, except under and in accordance with the terms of a permit issued under the authority of the Minister of Munitions; and, further, that no person shall sell, supply or deliver chrome ore of any grade except to the holder and in accordance with the terms of such a permit to purchase or take delivery as aforesaid.

DEALINGS IN CRUDE BENZOL, CRUDE NAPHTHA, AND LIGHT OILS.

The Minister of Munitions has issued an Order, under date 29th August, ordering that as from 1st October, until further notice, no person shall supply to any person, or take or accept or attempt to obtain delivery of any crude benzol, crude naphtha or light oils containing recoverable quantities of benzol or toluol, except under and in accordance with the terms and conditions of a licence issued by or under the authority of the Minister of Munitions, or under and in accordance with the terms and conditions of a contract in writing for the delivery of such articles existing at the date of this Order.

All persons engaged in producing, treating, distributing, storing, selling or dealing in crude benzol, crude naphtha or light oils, or in any manufacture, trade or business in which the same or any of them are used, shall make all such returns with regard to their businesses as may from time to time be required by or under the Authority of the Minister of Munitions.

For all purposes of this Order the following expressions shall have the meanings stated below:

"Crude benzol" and "crude naphtha" shall mean crude benzol and crude naphtha obtained by distillation of coal tar or extracted from coal gas, including benzolised wash-oil before separation of the crude benzol.

"Light oils" shall mean light oils obtained by the distillation of coal tar.

NOTE.—All applications in reference to this Order, including applications for Licences, should be addressed to the Director of Raw Materials Supply, Ministry of Munitions, Department of Explosives Supply, Storey's Gate, Westminster, London, S.W.1.

DEALINGS IN COAL TAR.

The Minister of Munitions has issued an Order, under date 14th September, which is to the following effect:—

1. No person shall as and from 1st October, until further notice, purchase or offer to purchase any coal tar (whether crude or dehydrated) except under and in accordance with the terms and conditions of a licence issued by or under the authority of the Minister of Munitions. Provided that no licence shall be required—

(a) By a tar distiller for the purchase of coal tar in any quantities, provided that the whole quantity purchased is intended to be and is in fact distilled by such distiller.

(b) By any person for the purchase of coal tar (whether crude or dehydrated) in quantities not exceeding ten gallons, provided that the total quantity purchased by any one person during any one calendar month does not exceed 50 gallons.

2. No person shall as from 1st October, until further notice, except under and in accordance with the terms and conditions of a licence issued by or under the authority of the Minister of Munitions, accept delivery of or make payment for any coal tar tendered for delivery under any contract existing at the date of the Order unless (a) such contract is in writing, and (b) full written par-

ticulars of such contract have been furnished to the Minister of Munitions before 1st October by the person for the time being entitled to deliveries thereunder.

3. For the purpose of this Order the expression "coal tar" shall mean and include tar produced or derived from the destructive distillation of bituminous material by any means other than blast furnaces.

NOTE.—All applications in reference to this Order (including applications for licences) should be addressed to The Ministry of Munitions, Department of Explosives Supply, Storey's Gate, Westminster, London, S.W.1, and marked "E.G.S."

Communications.

THE CATALYTIC BLEACHING OF OILS, FATS, AND WAXES.

BY HASHMAT RAI.

The general methods used for bleaching oils, fats, and waxes are:—

1. Spontaneous clarification, the oils and fats being allowed to rest for some prolonged time, when moisture, mucilaginous matter, etc., settle out.

2. Filtering over char or fuller's earth, or through a suitable filter at a suitable temperature.

3. Washing with boiling water.

4. Exposure to air and sunlight.

5. Exposure to ultra-violet rays.

6. Blowing air, oxygen, or ozone through the material at a suitable temperature.

7. Treating with manganese dioxide or potassium bichromate, and sulphuric acid.

8. Treatment with chlorine, bleaching powder, or potassium bichromate and hydrochloric acid.

9. Treatment with reducing agents alone or in presence of certain catalytic agents.

10. Blowing air, oxygen, or ozone through the heated substance in presence of certain catalytic agents.*

The processes adopted on a manufacturing scale vary essentially with the nature of the individual oil or fat.

The object of this investigation was to ascertain how far it is possible to bleach oils, fats, and waxes by blowing air through them at a suitable temperature in presence of certain catalysts.

Catalysts.

The catalysts used consisted of air-bleached palm-oil, oleates of manganese, copper, cobalt, lead, iron, and nickel. Silkstone soap of Messrs. A. Finlay and Co., Ltd., Belfast, and the cobalt salt of Silkstone soap. The metallic soaps were prepared by treating the chloride or the nitrate of the metal concerned with a boiling solution of sodium oleate or Silkstone soap, filtering the metallic soap in a Buchner funnel, and ultimately drying in a desiccator for a few days.

Apparatus.

The apparatus consisted of a glass flask fitted with a cork through which two holes were bored. Through one of them passed a glass tube flush with the cork and connected to a filter pump. A wash-bottle was interposed between the pump

* English Patent 17,784 of 1913 (this J., 1914, 1018). S. G. Sastry, Journ. Chem. Soc., 1915, 1828 (this J., 1916, 126).

and the bleaching flask. Through the other hole passed another tube reaching to the bottom of the flask. The bleaching flask was placed in a water-bath, the temperature of which was maintained throughout the experiments at 80°–90° C. Air was drawn by means of the filter-pump through the oil, fat, or wax contained in the bleaching flask, with or without the catalysts. Samples were taken at regular intervals on glass plates and compared with the best bleached sample supplied by Messrs. Alexander Finlay and Co. Temperature readings were taken after every fifteen minutes.

Palm-oil.

Two sets of experiments were performed with palm-oil. Two varieties, commercially known as "Sherbro" palm-oil and "Semi-soft" palm-oil, were used. The commercial oil was melted in a corrugated bucket and a little powdered common salt was added to the molten material. The oil was allowed to cool and to stand for 24 hours so as to separate water and other impurities which settled at the bottom. On cooling, the top portion was ladled off to an enamelled bucket and preserved for all the experiments. One pound and a half of the treated oil was used for an individual experiment and the desired amount of the catalyst was added to the heated oil. Samples were taken out after every hour.

presence of metallic soaps the time of bleaching is considerably shortened, especially in the case of cobalt and manganese salts, the cobalt salts being by far the best catalysts. It is remarkable and highly significant that both the oleate and the "Silkstone" soap of cobalt behave in exactly the same way. Thus "Silkstone" soap, which is cheaper than pure sodium oleate, can be used with advantage instead of the latter. Another striking point noticeable in Table I. is that manganese oleate acts as the second best catalyst of all, but at the same time it must be observed that cobalt salts are far dearer than manganese salts. On the whole it would be economical to use manganese soap for the commercial bleaching of oils in general and for palm-oil in particular.

Tallow.

Some experiments were tried with two commercial varieties of tallow, both treated and untreated. It was first heated and allowed to stand for some time to remove the impurities which settled at the bottom. The amount of tallow taken for each experiment varied between 24 oz. and 26 oz. Samples were taken out every half an hour in the case of the untreated tallow, and after every fifteen minutes in the case of the treated variety.

Table III. gives the experimental results :—

TABLE III.

No. of expt.	Variety of tallow.	Range of temperature.	Catalyst.	Percentage of catalyst.	No. of hours air was passed in.	Colour after expt.
.....	Untreated	100° C.	None	0.00	3.5	White
.....	Untreated	100° C.	Cobalt oleate	0.10	3.5	No improvement
.....	Treated	85°–90° C.	None	0.00	2.25	White
.....	Treated	85°–90° C.	Cobalt oleate dissolved in stearine.	0.11	2.25	Better white

The results of the experiments are summarised in the following tables :—

TABLE I.

Weight of "Sherbro" palm-oil, 1½ lb. Mean temperature, 80° C.

No. of expt.	Catalyst.	% of catalyst.	No. of hours that air was passed in.	Colour after expt.
1.	None.	0.00	19.5	White.
2.	Bleached oil from expt. 1.	0.12	19.0	White.
3.	Manganese oleate.	0.10	5.0	White.
4.	Copper oleate	0.10	9.0	Greenish.
5.	Cobalt oleate.	0.03	4.0	White
6.	Lead oleate.	0.10	16.0	White.
7.	Iron oleate.	0.10	17.0	Dirty white.

TABLE II.

Weight of "Semi-soft" palm-oil, 1½ lb. Mean temperature, 80° C.

No. of expt.	Catalyst.	% of catalyst.	No. of hours that air was passed in.	Colour after expt.
1.	None.	0.00	20.0	White.
2.	Nickel oleate.	0.10	15.0	White.
3.	Cobalt soap (Silkstone).	0.09	5.0	White.
4.	Cobalt oleate.	0.03	5.0	White.
5.	"Silkstone" soap.	0.12	17.0	White.

It will be seen from the above results that in

It is evident from the above results that cobalt oleate by itself does not act as a catalyst, but when dissolved in stearine before adding to tallow it does behave as a catalyst. This may be partially explained by the fact that cobalt oleate does not by itself dissolve in tallow and consequently does not take part in the reaction. On the other hand, when cobalt oleate is dissolved in stearine, it is diffused throughout the entire mass of tallow in a fine state of division and is in quite a suitable form to act as a catalyst. It may be that stearine also acts as a partial catalytic agent.

Beeswax.

Air was passed through about 4 oz. of beeswax for fourteen hours at a temperature varying between 85° C. and 100° C., but there was no visible sign of bleaching. Subsequently 0.37 grm. of cobalt oleate, i.e., 0.33%, was added, and the experiment continued at 100° C. for 6.5 hours without any effective bleaching. Then 2 grms. of tallow was added and the experiment again continued at 100° C. for 8.5 hours, but with no effect. Thus during a run of 29 hours; even on the addition of cobalt oleate and tallow, no improvement was obtained.

Commercial-scale experiments.

The laboratory experiments with palm-oil being highly successful, a few experiments on a commercial scale were conducted.

Palm-oil was heated in an autoclave by means of steam, and air was blown through it from an air-compressor.

The results are given in the following table :—

TABLE IV.
Weight of palm-oil, 25 cwt.

No. of expt.	Catalyst.	% of catalyst.	No. of hours that air was passed in.	Colour after expt.
1.	None.	0.00	14	White.
2.	None.	0.00	12—14	White.
3.	Cobalt soap (Silkstone).	0.08	4	White.
4.	Cobalt soap (Silkstone).	0.02	6	Dirty white.
5.	Cobalt soap (Silkstone).	less than	8	White.
6.	Manganese soap (Silkstone).	0.10	4	White.

Experiments 3, 4, and 5 were performed one after the other. In experiment 4 the colour of the oil was dirty white because of the suspended impurities; probably iron scale in a very fine state of division came off the bleacher. In experiment 5 no fresh catalyst was added, but only the bottom residues from experiments 3 and 4 were put in.

From the above results it is evident that cobalt and manganese soaps act as catalysts, and that both act equally well. Further it is found that even the bottom residues retain their catalytic properties. In experiments 3 and 4 the amount of catalyst is different, being in experiment 4 only one-quarter of that used in experiment 3. The difference in the duration of bleaching, though not great, is still appreciable.

Palm-oil is largely used in the manufacture of soaps and is generally bleached with potassium bichromate, which gives a very fine bleach to the oil. Hence it was considered desirable to compare the qualities of soaps prepared from the oil bleached by the bichromate and the catalytic processes respectively.

Two frames of soap about 20 cwt. each were made, one with the air-bleached palm-oil and the second with oil bleached by the bichromate process under similar conditions. The colour of the soap from the air-bleached oil was lighter than that of the soap from the oil bleached by the bichromate process. As regards hardness, there was no marked difference between the two qualities. The bichrome-oil looked cleaner but was far deeper in colour.

Summary and conclusions.

This investigation on the whole elucidates the following points :—

1. Most metallic soaps act more or less as catalysts in the bleaching of palm-oil and tallow, but not in the case of beeswax.
2. Different metallic soaps possess different catalytic properties.
3. With the same substance the catalytic effect depends to some extent on the amount introduced.
4. As regards the soap-forming quality, palm-oil bleached by the catalytic process is in no way inferior to oil bleached by the bichromate process.
5. The catalyst after being once used still retains its catalytic properties.

This work was carried out in the works of Messrs. Alexander Finlay and Co., Belfast.

I am indebted to Prof. F. G. Donnan, who suggested this work, for his valuable suggestions, and to Mr. Robert Finlay for his material help and the keen interest which he took in the investigation.

VULCANISATION CATALYSTS.

BY S. J. PEACHEY

(Municipal School of Technology, Mancheste.).

In a paper brought before the Annual Meeting of the Society by Dr. D. F. Twiss on the chemistry of vulcanisation (this Journal, 1917, 782), a comparison is made between the accelerating effect of *p*-nitrosodimethylaniline and that of certain alkalis, ammonium salts, and ammonia derivatives. Dr. Twiss prefaces the account of his experiments with the statement that "almost the whole of the known effective organic accelerators are basic, a rough proportionality apparently existing between their activity and their alkalinity, relatively feeble bases like aniline and methylaniline having little influence on the rate of vulcanisation," and his line of investigation appears to have been directed wholly from this standpoint. The erroneous impression that basicity is an invariable concomitant of accelerating power is thereby likely to gain ground, and as this may mislead other workers in the field, I think it is desirable to place on record one or two new facts which are opposed to the above view.

There can be little doubt that in the case of most of the known vulcanisation catalysts the accelerating power is in some manner bound up with the possession of basic or alkaline properties; further the results of numerous experiments which I have personally carried out point to the fact that the dissociation constant 1×10^{-8} referred to in Bayer's patent does actually form a dividing line between accelerating and non-accelerating bases and that all the useful accelerators of the basic type appear to be covered by their claim. Organic (and inorganic) bases, however, constitute merely a particular class of accelerator; there undoubtedly exists at least one other class represented at the present moment by certain organic compounds which contain the nitroso group directly linked to a benzene ring or similarly constituted nucleus. Of these *p*-nitrosodimethylaniline was the first to be discovered and is probably the most effective. The activity of accelerators of this type appears to be in no way connected with the possession of basic properties and such activity may be exhibited even by substances of distinctly acidic character. Even where accelerators belonging to this group are basic their basicity is naturally low and would probably in every case fall far below that represented by the dissociation constant 1×10^{-8} .

The following facts will suffice for the present to show that nitroso compounds owe their accelerating properties to the presence of the nitroso group directly connected with a carbon nucleus and not to any basic properties which they may happen to possess.

(1) Dimethylaniline (dissociation constant 2.4×10^{-10}) is destitute of any appreciable accelerating properties although it is a stronger base than *p*-nitrosodimethylaniline (dissociation constant 1.9×10^{-10}).

(2) *p*-Nitrosodimethylaniline possesses a dissociation constant lying far below 1×10^{-8} . Up to the present all the known powerful accelerators of the basic type possess a dissociation constant lying above this figure.

(3) *p*-Nitrosophenol and its homologues, although acidic in character, exhibit marked accelerating power.

(4) *p*-Aminophenol, in which the basic NH_2 group replaces the acidic NO group of the nitrosophenol, exhibits no appreciable activity.

(5) Whilst nitroso-bases are powerful accelerators the isomeric nitrosoamines (in which the nitroso group is not in direct combination with the nucleus) are inert.

Industrial Notes.

REPORT OF THE COMMITTEE OF THE PRIVY COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH, 1916-1917.

This Report has just been issued as a Government Paper (Cd. 8718, price 3d.). The Committee reports the progress made during the twelve months ending July 31st, 1917, and mentions the creation of the Imperial Trust for the Encouragement of Scientific and Industrial Research. The fund which the Government have placed at the disposal of the Committee will be deposited with the Trust and spent in the form of grants in aid of research undertaken by firms in any industry which may combine to conduct it on a co-operative basis. The Committee has approved the establishment, under the Companies' Act, of Associations for Research limited by guarantee and trading without profit.

During the year in question negotiations have been concluded with the Royal Society for the transfer of the property of the National Physical Laboratory, together with the responsibility for its maintenance and development, to the Department. The scientific management of the Laboratory will remain in the hands of the Executive Committee, which will be appointed as heretofore, but which, on its appointment, will become a Committee of the Department.

Mention is made of the appointment of the Fuel Research Board (see this J., 1917, 203), and the appointment by this Board of an Irish Committee of Inquiry into peat as a source of power (this J., 1917, 741).

The Committee has considered and approved recommendations in respect of aid to forty-four researches of industrial importance, and has expended some £3550 on grants to individual students and research workers.

Report of the Advisory Council.

This Report is divided into two parts, the first describing the steps taken to organise a systematic approach to the problem of industrial research, on a co-operative basis wherever possible; reference is also made to the appointment of new Standing Committees and to the development of Research organisations in the Dominions. In the second part an account is given of sporadic investigations aided or initiated by the Department and of grants made to research workers. The Report concludes with a discussion of means of encouraging inventors and aiding individual manufacturers.

Research Associations. The Council sees no difficulty in the establishment of trade research associations which could, where necessary, co-operate with existing corporations having similar objects. During the next few years the fund provided will be applied in founding and maintaining Research Associations in co-operation with the industries of the country; afterwards it is expected that the larger industries, at any rate, will be able and willing to carry on the work of the Associations without assistance. The Government intends to make a contribution to the assured income of such Associations from the subscriptions of their members, varying in amount according to circumstances. A model Memorandum of Association has been drafted, and notes prepared for the guidance of those desiring to draft the articles of an Association for Research; a short statement of the conditions under which the Department will make grants to such an Association is also given. In the constitution of the Governing Body

of an Association for Research, capital, management, and science must be represented, and it is believed further that provision should also be made for the inclusion of labour. It is intended that these Research Associations should include as many of the firms in each industry as possible, but it is recognised that where there is a great variety of applications as in the engineering industry, it may be advisable to form a series of distinct associations for research purposes. Everything possible will be done to encourage co-operation between different Associations. Progress has already been made in the establishment of an Association for Research in Cotton, and the woollen and worsted manufacturers have appointed a Committee to draft the Constitution for an Association. The Irish flax spinners are taking the same step, and the Scottish shale oil industry and photographic manufacturers have also decided to establish Associations immediately. The hope is also expressed that an Association for research into non-ferrous metals may soon be formed. In regard to chemical industries, the tendency towards financial combination among heavy chemical and allied manufacturers is noted, and it is pointed out that such combination will render co-operation for research alone less attractive, if not unnecessary.

Fuel research. The Council describes the steps which led up to the formation of the Fuel Research Board, and mentions some of the work which the Board is undertaking, including a survey of the coal resources of each district, the collection, examination, and classification of typical specimens of various coal seams, investigations into the nature and origin of the various types of coal, and into the chemical and physical behaviour of their constituents under the action of heat and other agents, the utilisation of peat, town gas standards, domestic heating, atmospheric pollution, etc.

Other researches. The Concrete Institute is controlling with the aid of the Department a series of tests of concretes made from selected local aggregates. Tests are also being made to ascertain the fire-resisting properties of different forms of concrete. Progress has also been made in research on refractory materials used by glass manufacturers, and with investigations into methods of stirring and melting which will protect the glass from furnace gases, etc. The development of the electric furnace, particularly for burning refractories at a very high temperature, has proceeded satisfactorily, and a new type of resistance furnace has been developed.

Investigations into the composition of optical glasses has been carried out, and the batch mixtures for several varieties of glass hitherto made exclusively at Jena, including fluor-crown glass, have been defined. Three new glasses, with properties hitherto unobtainable, have also been discovered. An investigation of abrasives and polishing powders, primarily in relation to their use in grinding and polishing glass, is about to be started. In this connection mention is made of the establishment of the Glass Research Institute at Sheffield University and of the Society of Glass Technology. Systematic surveys are being made of other fields for research, and it is mentioned that a report on iron and other metalliferous ores has already been issued (see this J., 1917, 698). A survey of the field for research in tungsten has been entrusted to a Sub-Committee under the chairmanship of Sir Robert Hadfield. Surveys are also being prepared in connection with the zinc industry, the smelting and refining of copper, the qualities of copper and the copper alloys, lubricants and lubrication, etc. A Sub-Committee has also been appointed to make a survey of the field for research in illuminating engineering.

A short account is given of certain researches which have been aided or initiated by the Council. These include work on light alloys, the corrosion of non-ferrous metals, refractories, hard porcelain, insulating oils, heat treatment of high speed steel, recovery of tin and tungsten, salting and disintegration of salts, and the degumming of silk. No details of the results of these researches are given, but it is indicated that satisfactory results have been obtained in several cases.

Assistance to inventors and manufacturers. The Department has no funds with which to assist patentees to exploit their inventions, but in certain suitable cases where funds are needed to work out on a full scale a process or device already patented, the Department is prepared to recommend a grant for the purpose. In suitable cases the Department will also consider applications for assistance towards researches necessary to perfect for commercial use patented or protected inventions or processes. Assistance will also be afforded to inventors through the medium of the Research Associations. To assist manufacturers, arrangements have been made with the Royal Society by which they assist the Council in selecting an institution or worker best fitted to undertake a research on behalf of a manufacturer; the Department will then in suitable cases provide the problems for research and also the funds for an assistant if necessary. Where a manufacturer shows keen anxiety to place his works on a scientific basis, the Department is prepared to entertain proposals to attach a young research worker to the works' laboratory, and to pay his salary during the early part of the term of his employment.

REFRACTORIES RESEARCH AND STANDARDISATION.

At the Second Conference on Refractories Research and Standardisation, held on July 11th, 1917, the Report of the Committee appointed at the first conference (see this Journal, 1917, 370) was adopted.

The Report is divided into three parts, dealing respectively with—(I.) Information as to refractory materials required by the various industries represented at the conference. (II.) Laboratory facilities for research work on refractories in public institutions in Great Britain and Ireland. (III.) The facilities existing in this country for publishing information on refractory materials and for collecting information and making it generally available.

Part I. is divided into seven sections. Section 1 deals with general requirements in regard to: (a) Particulars as to the distribution, resources, and properties of raw materials in Great Britain and Ireland, India, the Dominions, and the Colonies. (b) The investigation of certain physical, physico-chemical, and mechanical properties of refractories under service conditions. (c) Standardisation of tests and formulation of specifications in each class of material. (d) A study of the properties of all refractories and metallic oxides associated with them, up to the highest attainable temperatures, with special reference to their physico-chemical transformations. (e) Development of micro-technology as applied to refractories. (f) A special study of the rarer refractories.

Section 2.—Iron and steel industry. (a) *Raw materials.* (1) A comparative investigation of the special clays and other special raw materials used abroad, or formerly imported into this country, and their nearest British equivalent. (2) Complete analyses, approximate and ultimate, and mineralogical description of the principal raw materials available in this country. (3) Influence

of impurities on the inversion temperatures of the principal compounds used in the manufacture of refractory products. (4) An inquiry into the practicability of eliminating lime from dolomite with a view to manufacturing magnesite bricks. (5) The concentration, purification, and preparation of the raw material for the manufacture of chromite, bauxite, zirconia, and other rare refractory materials. (b) *Refractory products.* (1) An investigation of the physico-chemical changes that occur during the manufacture and subsequent utilisation under service conditions of the more important refractory products. (2) The influence of texture, bond, and previous thermal history of the principal refractory products on their durability under service conditions. (3) The erosion of refractory materials by rapidly moving currents of liquid steels and gases. (4) Physical and chemical properties of the more important refractory products at various temperatures, especially at the highest to which they are subjected during industrial service. (5) See also Section 3, Clauses *g* and *h*. (c) *Metallic alloys.* Reference is made to the use of metallic alloys whose particular properties render them valuable as refractory materials. The use of alloys of silicon and iron where acid liquors are contained or transferred is firmly established in practice, and might be extended if their properties were more widely known. Certain alloys with chromium as a dominant constituent, possessing great mechanical strength and retaining the high degree of thermal conductivity that characterises the metals, can be subjected to temperatures in the neighbourhood of 1000° C. under oxidising conditions without deterioration. The significance of this can hardly be over-estimated, for it would only be necessary for a comparatively small rise in the upper limit of the available temperature range to be achieved, when the claims of counter-current recuperation as opposed to reversible regenerators or stoves for smelting, melting, and reheating by-product coke-ovens, gas-retorts, furnaces, etc., would have to be seriously considered. Certain alloys of titanium and iron are insoluble in molten steel, and have a melting-point certainly higher than 1600° C. and probably near 1850° C. The possibilities of titanium alloys as refractory materials are thus strongly suggested. There is little reason to doubt that an investigation of the metallic alloys mentioned, and of others that might suggest themselves, with a view to determining their properties as refractory materials, could not fail to furnish results not only of limited application, but possibly of far-reaching significance.

Section 3.—Non-ferrous metal industry. (a) In the copper industry research is particularly necessary in the direction of securing bricks—or other forms of refractories—having a high resistance to the cutting action of copper slag; the question of brick bottoms for reverberatory furnaces used in copper smelting and refining also needs attention. (b) In the aluminium industry there are needed:—(1) Improved refractory insulating material in reduction furnaces. (2) Improved bricks for use in furnaces for calcining coke. (3) Researches relating to the manufacture of carbon (graphitic and amorphous) electrodes, including the construction of saggars for baking electrodes. (c) Refractories for retorts used in zinc distillation. (d) Problems connected with plumbago and other crucibles. (e) Investigation into the best material for linings of pit-fired type furnaces used for:—(1) Brass and alloys at about 1150° C. (2) Cupro-nickel and similar alloys above 1400° C. (3) Crucible melting of steel. (f) Linings for coke, gas, and oil-fired tilting furnaces with air or gas under pressure. Effect of the blast on refractory linings.

Section 4.—The gas industry. (a) See Section 2, Clauses (a) 1, 2 and 3, (b) 1 and 2, and (c). The clauses apply to the gas industry also. (b) Study of clay for jointing purposes. Influence of adding grog to cement used in retort settings. (c) Relative effects of oxidising and reducing gases on refractoriness, and on after expansion and contraction. (d) The influence of the flue dust carried into the settings with the furnace gases, and of the mineral constituents of the coal carbonised on the refractoriness and life of the material employed. (e) Investigation of the effect of the admixture of highly silicious rock, such as ganister (raw or calcined), on the working quality of fire-clay goods. (f) Further investigation of the most suitable means to be used in the manufacture of the retorts used for the carbonisation of coal, in order that these may withstand temperature fluctuations to which they are exposed, owing to their periodic filling with cold coal when at high temperature, and at the same time render them impervious to the passage of gases. (g) Coke-oven and retort linings to resist action of salt vapours and steam. (h) The development of a material which will conduct heat more quickly to the charge.

Section 5.—The chemical industry. The industry requires materials to withstand both acid and alkali gases and liquids at moderately high temperatures. Effects of reducing and oxidising flames must be studied. Information at present is in the hands of users and not manufacturers of refractories. There is no uniformity in material at present available. Enamels to resist acids and alkalis and which will transmit heat are required in the fine chemical industry.

Section 6.—The glass industry. (1) Study conditions which determine corrosion, dissolution, and pitting of bricks, blocks, and pots in glass furnaces. Consider especially effect of composition, texture, and impurities (e.g., titanium oxide). (2) Investigation with regard to materials best suited for glass furnaces. Substitutes for some of the best grade materials at present used. (3) Study of protective coating and washes. (4) Methods of purifying fire-clay. (5) Use of non-calcined material, such as stone blocks. (6) Study of possibilities of water-cooled tanks. (7) A geological research in all measures to find out where the change from fresh-water to salt-water conditions of deposition took place. (8) A geological research in the Lancashire coal beds for refractory materials.

Section 7.—The pottery industry. The firebricks employed in pottery manufacture for oven, muffle, and kiln building are covered by the requirements indicated for the other industries. Similar remarks probably obtain for the bricks used in frit-kiln bottoms, for they are required to withstand the action of highly corrosive molten lead and alkali silicates and borates. The saggar question is an important one, since saggars require a high tenacity and high temperature crushing strength, resistance to sudden or abrupt changes of temperature, and they must also be free from impurities which are liable to spurt. The question of high-temperature porcelains will be taken in hand shortly, and this will require much more resistant saggars than are at present in use. Study of porcelains for high voltages, or having a high electrical resistance when heated.

Part II. deals with laboratory facilities for research work on refractories in public institutions in Great Britain and Ireland, and Part III. details the facilities existing in this country for publishing information on refractory materials and making it generally available. In this connection the Committee, having given consideration to the present position as to abstracts, submitted the following Resolution:—"Resolved, that with a view to

rendering the work hitherto done by the Ceramic Society more readily useful, the Societies and Institutions represented at the Conference on Refractories held on March 22nd, 1917, co-operate in the preparation of a complete index with Abstracts of important papers on Refractories, and their publication in a form that will render them available for the members of the co-operating Societies."

WOMEN IN CHEMICAL INDUSTRIES.

In a pamphlet issued by the Home Office and the Board of Trade on the employment of women in chemical industries, it is stated that substitution of women for men has taken place in all the principal centres of the industry and has made appreciable advance both in direction and extent during the past fourteen months. Owing to the heavy nature of some of the work and to the fact that in the past it has been customary for the same man to be employed on different kinds of work, some too heavy for women, some comparatively light and suitable for them, a certain amount of re-organisation and adaptation is necessary in order to enable women to be successfully brought in.

The following is a list of the processes in which women have, under suitable conditions, already been or can be successfully substituted for men. Processes not included in the list are those in which inquiry has not at present discovered cases of successful substitution:—

Alkali and acid manufacture.

1. *Alkali.*—Emptying roll sulphur moulds. No substitution has been found in the process of alkali manufacture proper.

2. *Acid.*—Filling, stoppering, and packing carboys.

Manufacture of light chemicals.

1. *Filter press work.*—Scraping and cleaning ordinary filter presses. Manipulating pump or valve regulating the flow of liquor. Screwing-up, emptying and cleaning gravity filter press. Working hydraulic press; for example, for compression of guncotton and for oil extracting.

Centrifugals or hydro extractors.—Loading, working, and emptying centrifugals (up to 50-inch cage diameter).

Electro-chemical processes.—Refining and separation of metals. (The adoption of women's labour to any great extent in this department, e.g., in copper refining, depends on the size of the cells and on the use of lifting tackle when the anodes and cathodes are too heavy.*) Feeding cells with solution. Removing deposit of precious metals from cells. Fitting cells with carbons and making plastic parts of cells. Making cell luting.

Management of stills.—Supervision of water distillation plant.

Feeding or working the following machines.—(i.) Feeding only: Disintegrator. Mechanical sieve. Grinder. Bucket elevator. Edge runner. (ii.) Working: Band saw. Using hand, over-head, lifting tackle (for moving drums up to 1 ton in weight).

Laboratory work—skilled and unskilled.

Emptying cooling or crystallising tanks. † (Use

* The Factory Inspectors consider that women could satisfactorily be employed to a greater extent than has been yet attempted on the management of cells.

† (i.) Women have been found employed on coolers (or crystallising tanks) 5 feet 6 inches deep. Two women emptied and one carried away. A strong type of woman is essential. One cooler containing over two tons of material would be emptied daily. Women have been employed on borax coolers for years and are considered satisfactory.

(ii.) It is desired to call the attention of employers to the possibility of employing women on the analogous operation of emptying sulphur tanks in the chance recovery process—in which the work is certainly less arduous than that involved in the above case.

of lighter picks and shallower coolers desirable.) Breaking up solid crystals (except large blocks requiring the use of a heavy pick or crowbar). Drying-cupboard work. (i.) Conveying drying shelves or solids. (ii.) Spreading out and raking over solids. Emptying subliming chambers. Stacking blue beds in white lead works. (Performed in some factories prior to the war.) Feeding and supervision of small boiling pans, and of reaction vessels. Supervision of evaporating tanks. Washing crystals in fine chemical works. Siphoning liquors into crystallising tanks.

Dry packing generally. Wet packing. Soldering tins and tin-paper linings of cases. Weighing and packing copper ingots. Storekeeping. Checking for dispatch.

General labouring work.

Unloading boats and trucks of slack, coal, coke, fire-bricks, timber, sand, and drain pipes. Loading barges with coal, etc., and trucks with sacks. Filling and wheeling barrows (loads up to 1½ to 2 cwt., including barrow). Wheeling carboys of acids. Washing, rolling, and painting iron drums. Bagging coke, chemical manure, etc. Cleaning and emptying evaporating tanks. General cleaning operations. Trimming coal for furnaces, and levelling ashes. Washing bogies. Breaking up pyrites. Carting.

The greater part of the operations performed require no special training or skill apart from careful instruction at the works in methods of tackling and of systematically arranging the work. Practice in hard manual labour and strict intelligent attention to instructions are chiefly necessary. In certain exceptional operations—for example, management of vacuum stills—long experience appears requisite for rapid appreciation and successful control of different combinations of causes which may affect the work, and which it is said to be almost impossible to schedule for the guidance of the new worker.

Women of strong physique are required for much of the work and intelligent women of a superior type for that which is more responsible. A careful selection of workers, with reference to the particular class of operation, is the primary condition of successful substitution. It is not anticipated that there will be any difficulty in securing the right type of worker if suitable arrangements are made and adequate remuneration is offered.

In certain branches, the necessity of carrying on the work continuously makes the introduction of women dependent on some relaxation of the law. Applications for such relaxations will be favourably

considered by the Home Office where they are needed to facilitate production of supplies for the Crown, or to enable other work required in the national interest (e.g., manufacture for export) to be carried out. The attention of employers is particularly directed to the arrangement found in certain parts of the country of working in eight-hour shifts, which appears specially suited for introduction of women's services.

Special arrangements of a simple and practical character are necessary to render the heavier and more dangerous work suitable for women. A good example of labour-saving arrangements in connection with the loading and unloading of trucks is the erection of rough platforms with access by planks on a gentle incline, which have been found of great service. Other mechanical appliances, such as arrangements for "blowing over" liquors instead of carrying by hand; introduction of lifting tackle where heavy plates, etc., have to be lifted and of lighter implements (barrows, pulleys, spades, etc.); and the provision of suitable protective clothing for wet, dangerous, and dirty processes, have facilitated introduction of women.

Correspondence.

SIR,

I have read with interest Mr. McLellan's note on "Boiler Corrosion" (this J., 1917, pp. 853—856) and I think that in the addendum he has proved that the corrosion was due to electrolytic action. Nitrogen, in apparatus with rubber connections, is more satisfactory than hydrogen.

A layer of oil is useless for preventing the transmission of the gases of the air. This fact, though mentioned by two speakers in the discussion, is not well known. I found some time ago that the absorption of oxygen from air by water under relatively thick layers of various oils was considerable. Gniewosz and Walfisz (Zeits. physik. Chem., 1, 70) found that "the coefficient for the absorption of oxygen and many other gases by petroleum is much higher than that for water. The authors consider it illusory therefore to try to protect liquids from oxidation by covering them with a layer of petroleum." (Abstract; this J., 1888, 772.) The petroleum layer is a weak point in Ramsay and Homfray's method for the determination of dissolved oxygen (this J., 1901, 1071).

Yours, etc.,

Aug. 30, 1917.

J. H. COSTE.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Feron 8, Paris (2e.)

Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Granular calcium chloride as a drying agent. A. T. McPherson. J. Amer. Chem. Soc., 1917, 39, 1317—1319.

Air containing a known amount of water vapour was aspirated over a long column of anhydrous granular calcium chloride and the residual moisture absorbed and weighed in a glass-stoppered phosphorus pentoxide tube. The calcium chloride had been previously dried at 260°—275° C. in a current of air dried over phosphorus pentoxide. A tube

100 cm. long and 2 cm. diam., filled with the dry calcium chloride and kept at 25° C., removed at a rapid rate (9 litres per hr.) the whole of the weighable moisture from a fairly large volume of air (40 litres) saturated with water vapour at 25° C. The amount of air that may be dried at maximum efficiency decreases as the rate of passage increases but not in the same proportion, the rate at 23 litres being about half as great as at 5 litres per hour. Experiments showed that the efficiency of a calcium chloride drying tube depends upon the volume of gas and the rate of flow rather than on the amount

of moisture in the gas, and that granular calcium chloride when absolutely dry will remove every trace of moisture from a gas passed over a sufficiently long column of it.—J. H. P.

PATENTS.

Refrigeration; Process of mechanical — J. C. Bertsch, Edgewood Park, Pa., U.S.A. Eng. Pat. 101,514, Sept. 13, 1916. (Appl. No. 13,015 of 1916.) Under Int. Conv., Sept. 17, 1915.

The working liquid used has a higher specific gravity but a lower boiling point than water, as for example carbon tetrachloride. It is sprayed into the refrigerating chamber, evaporated, and the vapour withdrawn by a vacuum pump and compressed. The compressed vapour is delivered into a condenser below the level of the condensed liquid. The condensed liquid is sealed by a layer of water, or water and glycerin, which also serves as a lubricant. The condenser is open to the atmosphere and is provided with a coil through which water is passed to carry away the heat of condensation, and with an overflow by which the sealing water can pass to the compressor to serve as a lubricant. The liquid to be cooled is passed through a coil in the evaporator chamber.

—W. H. C.

Separators; Magnetic — O. C. Jones, Maidstone, Eng. Pat. 107,284. (Appl. Nos. 11,064, Aug. 5, and 15,643, Nov. 2, 1916.)

Two or more permanent or electro magnets are provided with pole pieces and so arranged that a narrow tunnel-like passage is left between the pole pieces through which the material to be treated is passed from a non-magnetic duct. The apparatus is intended primarily for separating particles of iron from semi-liquids such as paper pulp, potters' slip, etc., but may also be used with granular or finely-divided materials.—W. H. C.

Furnaces; Heating — Stein and Atkinson, Ltd., and J. S. Atkinson, London, and Kayser, Ellison and Co., Ltd., and C. W. Kayser, Sheffield, Eng. Pat. 107,332, Nov. 18, 1916. (Appl. No. 16,550 of 1916.)

The furnace is furnished with two sets of flame inlets and outlets, which have separate regulators in order that the rate at which the material is heated or cooled may be varied at will. A recuperator is provided below the furnace in which the air and/or gas flow vertically upwards through small passages and the heating agent flows horizontally through relatively wide passages.

—W. H. C.

Furnaces; Gas-fired — I. Hall, Birmingham, Eng. Pat. 107,876, Sept. 20, 1916. (Appl. No. 13,318 of 1916.)

In a gas-fired furnace using air under pressure, the gas and air are supplied to the burners from separate distributing chambers, and the nozzles or burner caps (see Eng. Pat. 12,695 of 1915) which deliver the mixture of gas and air tangentially into the combustion chamber, have conical mouths and are arranged just outside the apertures, so that the gaseous mixture will induce a current of secondary air into the openings.—W. H. C.

Steam and gas superheaters, heating and cooling appliances — E. E. Tasker, Brentwood, Eng. Pat. 107,821, July 14, 1916. (Appl. No. 9923 of 1916.)

The ends of the superheater pipes are connected with the steam-chests by means of conical plugs and seats. The ends of the pipes are provided with flanges over which a collar fits. The joints are tightened by nuts and studs which pass through the collars.—W. H. C.

Cleansing various materials or objects for domestic and industrial purposes; Process for — O. Röhm, Darmstadt, Germany, Eng. Pat. 107,191, May 18, 1916. (Appl. No. 7091 of 1916.) Under Int. Conv., Apr. 12, 1915. Addition to Eng. Pat. 2151 of 1915 (this J., 1915, 1204).

An aqueous liquid prepared by adding pancreatic or tryptic enzymes to water, approximately in the proportion of 0.5—1 gm. of pancreatin to 100 litres of water, is employed for cleansing furniture, fittings, bottles, and utensils other than textile articles.—J. F. B.

Condensers for refrigerating machines — B. S. McClellan, Chicago, U.S.A. Eng. Pat. 108,196, July 27, 1916. (Appl. No. 10,623 of 1916.)

SEE U.S. Pat. 1,201,208 of 1916; this J., 1916, 1206.

Apparatus for harvesting the constituents of wood and vegetable substances, distilling and purifying them — U.S. Pat. 1,231,247. See V.

Appliances for ascertaining the hardness of metals and other solid materials — Eng. Pat. 107,685. See XXIII.

II A.—FUEL; GAS; MINERAL OILS AND WAXES.

Mine gases and industrial gases; Limits of complete inflammability of mixtures of — with air. G. A. Burrell and A. W. Gauger, U.S. Bureau of Mines Tech. Paper No. 150. 1917. 11 pages.

THE report summarises the results of experiments to determine the above limits, dealing with gasoline vapour, ethane, methane, natural gas, acetylene, illuminating gas, blast-furnace gas, and hydrogen. Flame is said to be self-propagated through a mixture when enough of the combustible gas is present to permit combustion to spread through the mixture from any given point of ignition, the propagation of flame then taking place from layer to layer without the continued presence of the igniting source of heat. The limits are slightly affected by varying conditions, being lower when ignition occurs from the bottom than when it occurs from the top. The limits of complete inflammability are shown by the following percentages of the particular gas in air. Gasoline vapour, 1.5 to 6; ethane, 2.5 to 5; methane, 5.5 to 14.5; natural gas, 5 to 12; acetylene, 3 to 73; illuminating gas, 7 to 21; hydrogen, 10 to 66; carbon monoxide, 15 to 73; blast-furnace gas, 36 to 65. Variations in pressure and temperature affect the above figures only very slightly. With reference to the use of oxygen, the low limits of inflammability are apparently not much affected thereby, but in the case of methane the higher limit was raised from 14.5 to 45%, and presumably the upper limits with other gases would be similarly affected. Details of tests on blast-furnace gas are given, and typical analyses of such gases from various types of furnaces. In general, the lower limit for blast-furnace gas varies with the amount of combustibles present in the gas from 36 to 57%. The upper limit is, however, approximately 65% of gas for all cases.—J. E. C.

Lubricating oils; The testing of — H. K. Moore and G. A. Richter, Met. and Chem. Eng., 1917, 16, 692—694.

An apparatus has been devised to measure relatively the durability and also the internal friction or "power consumption" of the oil. It consists essentially of a conical bearing, with a vertical angle of 30°, rotating in a conical sleeve, the latter being long enough to take cones of different sizes.

The desired pressure is maintained by a suspended weight of 100 lb. acting on the shaft. The conical sleeve is jacketed to maintain any desired temperature at the bearing surface. The revolving cone is furnished with a spiral feeding groove to bring the oil to the bearing surface, the oil travelling through the hollow shaft to a small oil pump which returns it to the bearing surface. The shaft is rotated at 80 revs. per minute by a motor through a gear drive, and the power consumption is measured by an ammeter and voltmeter. Knowing the efficiency of the motor, the results obtained are strictly comparable. Where the power consumption is the determining factor, the input in watts is plotted against time, and the "durability" of the oil may thus be studied. In another method of testing, the oil pump is not used, and the oil is dropped on the bearing as required to keep the power input below a pre-determined limit, the amount of oil required per hour being thus obtained; or the lower end of the groove may be plugged, and 3 c.c. of oil added to the bearing, the power input being recorded each minute. The machine is allowed to run until a maximum allowable power input is reached and the power is plotted against time. In one series of experiments the amperage of the motor was allowed to reach 3.4, the voltage being kept constant at 120, and at the end of each run the bearing was cooled to the starting temperature of 20° C. before beginning another run. It has been noted that the oil which "stands up" for the longest period of time without exceeding the allowable power consumption, requires a comparatively higher power input during that time than other oils which reach the predetermined maximum in shorter time. The cost of the lubricant and power must be considered in selecting the most economical oil, and the most economical is not necessarily the most suitable, as the bearing temperature, gumming, and cold test must also be considered.

—B. N.

Unsaturated organic compounds; Action of anhydrous aluminium chloride on —. H. W. C. Gangloff and W. E. Henderson. J. Amer. Chem. Soc., 1917, 39, 1420—1427.

Dry aluminium chloride absorbs gaseous unsaturated hydrocarbons very slowly, but in solution the combination is much more rapid. *Acetylene* passed into a solution of aluminium chloride in absolute ethyl alcohol yielded a light yellow, granular, very hygroscopic product, $\text{AlCl}_3 \cdot \text{C}_2\text{H}_2 \cdot 2\text{C}_2\text{H}_5\text{OH}$, which decomposed very readily on standing. Using purified methyl alcohol as solvent a similar product was obtained, $\text{AlCl}_3 \cdot \text{C}_2\text{H}_2 \cdot \text{CH}_3\text{OH} \cdot \text{H}_2\text{O}$. *Ethylene* gave $\text{AlCl}_3 \cdot \text{C}_2\text{H}_4 \cdot 2\text{C}_2\text{H}_5\text{OH}$ with ethyl alcohol as solvent and with methyl alcohol $\text{AlCl}_3 \cdot \text{C}_2\text{H}_4 \cdot \text{CH}_3\text{OH} \cdot \text{H}_2\text{O}$. *γ-Butylene* with methyl alcohol as solvent gave a product $\text{AlCl}_3(\text{CH}_3)_2\text{C}(\text{CH}_2\text{CH}_2\text{CH}_2\text{OH})_2$. *β-Isomylene* (b.pt. 36°—38°) when treated with dry aluminium chloride gave a series of yellow to red to sienna coloured tars as the amount of chloride was increased. The tars on fractionation from solution in alcohol produced carbinols, principally trimethylcarbinol. In alcoholic solution a crystalline product, $\text{AlCl}_3 \cdot \text{C}_5\text{H}_{10} \cdot \text{CH}_3\text{OH}$, was obtained. *Phenylethylene* gave two products, one of which is $\text{AlCl}_3 \cdot \text{C}_6\text{H}_5 \cdot \text{CH}(\text{CH}_3)$. In this instance water or alcohol of crystallisation appears to be unnecessary for the formation of a crystalline body. On standing loosely stoppered for six months it lost its crystalline character and became oily. The oil proved to be $\text{AlCl}_3 \cdot 2\text{C}_6\text{H}_5 \cdot \text{CH}(\text{CH}_3) \cdot 2\text{H}_2\text{O}$. *Oleic acid* mixed with aluminium chloride in methyl alcohol gave a crystalline mass like brown sugar which on analysis was found to be $4\text{AlCl}_3 \cdot \text{C}_{18}\text{H}_{33}\text{COOH}$. *Fumaric acid* used in varying amounts gave $\text{AlCl}_3 \cdot \text{C}_4\text{H}_4\text{O}_4$

in every case. *Furfuraldehyde* with a methyl alcohol solution of aluminium chloride produced $\text{AlCl}_3 \cdot \text{C}_5\text{H}_4\text{O}_2 \cdot \text{CH}_3\text{OH}$. *Benzaldehyde* gave $\text{AlCl}_3 \cdot \text{C}_6\text{H}_5\text{CHO} \cdot \text{CH}_3\text{OH}$. *Allyl alcohol* gave $\text{AlCl}_3 \cdot \text{C}_3\text{H}_5\text{O} \cdot \text{CH}_3\text{OH}$. Anhydrous ferric chloride gave similar reactions to aluminium chloride but they were less vigorous and not so complete. In the preparation of benzophenone from benzoyl chloride and benzene, aluminium chloride gave a yield of 70—71% as against 60—62% obtained with ferric chloride and 28—32% with zinc chloride. All the compounds of aluminium chloride described above are crystalline and are mostly unstable. They have no definite melting points, dissociation occurring before fusion. The possibility of compounds of aluminium chloride with unsaturated hydrocarbons being formed in the treatment of petroleum is considered. (See also this J., 1916, 917.)—J. H. P.

PATENTS.

Fuel; An improved —. R. Hleemann, Glasgow. Eng. Pat. 107,344, Jan. 2, 1917. (Appl. No. 25 of 1917.)

An improved fuel is composed of bitumen or pitch, an argillaceous substance, and a carbonaceous substance. The argillaceous substance is made fluid by addition of water, and poured into the molten pitch. The carbonaceous matter is then incorporated, and the mass pressed into blocks.—J. E. C.

Mine waste; Utilisation of — by means of the heat of waste fields. W. Ostwald, Grossbothen, Saxony. Eng. Pat. 107,446, July 25, 1916. (Appl. No. 10,462 of 1916.)

In dealing with rubbish heaps from collieries, oil shales, etc., solutions of chlorides such as sodium chloride are introduced to the burning heap through a series of tubes to convert the combined nitrogen into ammonium chloride, and another series of tubes is inserted for carrying off the resulting products. Separate cooling elements may be embedded in the portion of the waste heap being worked at any time, to reduce the temperature and avoid the formation of slag.—J. E. C.

Coke ovens; Regenerative —. A. G. Bloxam, London. From E. Coppee et Cie., Brussels. Eng. Pat. 107,879, Sept. 23, 1916. (Appl. No. 13,540 of 1916.)

An installation of regenerative coke ovens, adapted to be heated by poor or rich gas, is provided with regenerators arranged longitudinally with relation to the battery, and in two rows of sub-sections fitted end to end. One row at any particular period is receiving hot spent products of combustion, the other row at this same period being so arranged that one-half of the chambers is heating the poor gas and the other half is heating the air. The sub-sections dealing with gas are connected to a common hot gas flue, and the air sections to a common hot air flue respectively, whilst these two flues deliver their products to the base of the vertical flues of the oven proper. The division into sub-sections allows better control of temperature in each section, and the use of a common flue secures a more uniform temperature along the whole battery, whilst an individual sub-section may be repaired without stopping the whole plant.

—J. E. C.

Vertical [gas] retorts; Heating of —. P. G. Strassmann, Crefeld-Linn, Germany. Eng. Pat. 107,308, Sept. 15, 1916. (Appl. No. 13,006 of 1916.)

A VERTICAL retort adapted for continuous working is divided into three zones. Gas and air are fed into flues round the central portion of the retort constituting the main heating chamber. The

heated products of combustion rise vertically through flues surrounding the upper or preliminary distillation chamber, the heat of which gradually decreases towards the top. The lower section is surrounded by air- or water-cooled passages and constitutes a coke-cooling chamber. The air for combustion is preheated by the heating gases and the products of combustion.—J. E. C.

Carburetting air to form a gaseous fuel for internal combustion engines. C. M. Dyer, Hawthorn, Victoria, Australia. Eng. Pat. 107,357, Feb. 26, 1917. (Appl. No. 2793 of 1917.)

AN atomising device for carburetting air comprises a jacketed tapering casing with a number of gauze screens graduated in fineness of mesh from the inlet to the outlet. An auxiliary air admission device is fitted to the upper part of the casing, and a cylindrical or dome-shaped screen of gauze is placed over the inlet.—J. E. C.

Gas producers. The Tyne Glass Works, Ltd., Gateshead, and A. B. Roxburgh, Monksheaton. Eng. Pat. 107,525, Nov. 24, 1916. (Appl. No. 16,864 of 1916.)

THE stepped grate of a gas producer is composed of fluted or grooved bars adapted to be rotated on their axes. Water is conveyed to the grooves, and each bar may be withdrawn without interfering with the remainder.—J. E. C.

Gas producers. A. Sahlin, London. Eng. Pat. 107,561, Apr. 12, 1917. (Appl. No. 5160 of 1917.)

IN a gas producer having a central tuyère, means are provided for varying the area of one or more of the blast apertures to regulate the relative rate of combustion in the different zones of the fuel bed. Such means may be operated during the working of the producer without affecting the wind pressure in the wind box behind the blast apertures.—J. E. C.

Gas producers. D. Moffat, Wishaw. Eng. Pat. 107,567, May 7, 1917. (Appl. No. 6485 of 1917.)

IN connection with a gas producer, a pair of pivoted dampers with interlocking edges is provided within the gas outlet passage, along with lever mechanism for operating the dampers from the outside.—J. E. C.

Heavy hydrocarbons; Method of converting — into light hydrocarbons or hydrocarbon gases. F. B. Dehn, London. From Synthetic Hydrocarbon Company, Pittsburg, U.S.A. Eng. Pat. 17,822, Dec. 22, 1915.

THE heavy hydrocarbons are cracked by being passed into a tube suitably heated, *e.g.*, by electrical means, and containing at the top a small quantity of refractory filling material, such as steel balls. The gaseous products are drawn off by means of a suction pump through suitable condensing apparatus and the condensed liquid collected, the gases being passed into a gas-holder. The pressure should be below $\frac{3}{4}$ atmos. (absolute), the best yields being obtained below 4 lb. pressure. It is claimed that, by controlling the various factors, *i.e.*, rate of feed, temperature, and pressure, certain compounds, *e.g.*, benzene, toluene, ethylene, etc., can be caused to predominate in the reaction products. Also, as the gases are immediately drawn off from the cracking tube, polymerisation and the formation of undesired products is prevented. (Reference is directed, in pursuance of Sect. 8, Sub-sect. 2, of the Patents and Designs Act, 1907, to Eng. Pats. 9162, 9163, and 13,100 of 1915.)—L. A. C.

Liquids; Treatment of — with gases. [Production of motor fuel.] C. F. Killar, London. Eng. Pat. 107,217, May 19, 1916. (Appl. No. 7173 of 1916.)

TO obtain products suitable for use in internal combustion engines, a liquid hydrocarbon oil is sprayed in an atomised condition into a vessel filled with a gaseous hydrocarbon, *e.g.*, acetylene. To prevent subsequent separation, a small quantity of ether, acetone, or alcohol is previously added to the liquid hydrocarbon.—W. H. C.

Liquid fuels. G. E. Heyl, London. Eng. Pat. 107,454, July 31, 1916. (Appl. No. 10,781 of 1916.)

MIDDLE oil from coal tar, distilling from 170° C. to 230° C., is redistilled at a lower temperature, and a portion collected having a flash point up to about 35° C. The middle oil is previously neutralised, washed, and freed from naphthalene. By continuing the distillation, an oil with a flash point of 38° to 49° C. is obtained and the latter oil may be washed with sulphuric acid to decolorise it.—J. E. C.

Coke-ovens or other ovens, furnaces, or the like; Apparatus for manipulating the doors of by-product —. E. Blythe and C. Armitage, Dewsbury. Eng. Pat. 108,236, Sept. 27, 1916. (Appl. No. 13,728 of 1916.)

Coke; Method of improving — as heating medium for stoves and the like. Schollkohlen-Ges. m.b.H., Assignees of E. and A. Schollenbruch, Düsseldorf, Germany. Eng. Pat. 100,968, July 24, 1916. (Appl. No. 10,425 of 1916.) Under Int. Conv., July 22, 1915.

III.—TAR AND TAR PRODUCTS.

Vacuum tar; Hydroxy-compounds and bases of —.

A. Pictet, O. Kaiser, and A. Labouchère, Comptes rend., 1917, 165, 113—116. (See also this J., 1913, 1098; 1914, 70; 1915, 604.)

VACUUM tar contains about 2% of hydroxy-compounds and 0.2% of bases. The bases were extracted with dilute hydrochloric acid, separated by fractional distillation, and purified as picrates. The hydroxy-compounds were separated from the tar as solid sodium phenolates, and fractionally distilled. The substances thus isolated are shown in the table, which reveals an interesting parallelism between the series of hydroxy-compounds and bases. The only product definitely identified was

Hydroxy compounds.	B.pts. °C.	B.pts. of acetates. °C.	Bases.	B.pts. °C.	M.pts. of picrates °C.
$C_7H_{11}O$	170—175	—	C_7H_9N	198—203	170
$C_8H_{10}O$	185—190	—	C_8H_7N	225	195
C_9H_9O	198—200	213—215	C_9H_5N	247—250	184
$C_{10}H_8O$	213—215	226—229	$C_{10}H_3N$	250—260	184
$C_{11}H_6O$	226—228	240—244	$C_{11}H_1N$	260—265	173
			$C_{12}H_1N$	270—280	166

the lowest hydroxy-compound, $C_7H_{11}O$, hexahydro-*p*-cresol. The others, forming a homologous series, differed from this in properties. Insoluble in alkalis when freshly prepared, they gradually became soluble, and from the solutions thus formed carbon dioxide precipitated phenolic substances. These compounds, unlike the lowest of the series, $C_7H_{11}O$, were unsaturated. Their acetic esters, readily obtained by means of acetyl chloride, were colourless liquids of pleasant odour, and instantly decolorised permanganate in cold sulphuric acid solutions. These hydroxy-compounds probably occur as such in coal, for those found in benzene extracts of coal appear to be similar. The series of bases showed corresponding differences. The lowest fraction (b. pt. 198°—203° C.) behaved as a primary aromatic amine and may possibly have been a mixture of toluidines. The other members of the series, on the contrary, were saturated secondary bases. They were colourless liquids, somewhat resembling the quinoline bases in odour, and yielded picrates only slightly soluble in alcohol. They are probably decomposition products of alkaloids present in coal.—J. H. L.

o-Nitroamines; Conversion of — into iso-oxadiazole oxides and of o-nitrosoamines into iso-oxadiazoles. A. G. Green and F. M. Rowe, Chem. Soc. Trans., 1917, 111, 612—620.

IN previous papers (Chem. Soc. Trans., 1912, 101, 2452; 1913, 103, 897, 2023; this J., 1913, 904) it was shown that many *o*-nitro-amines are converted into furoxans (furan oxides or iso-oxadiazole oxides) when oxidised in alkaline solution with sodium hypochlorite. The same reaction has been studied in the naphthalene series

and it was found that 2-nitro-1-naphthylamine and 1-nitro-2-naphthylamine both gave the same oxidation product, naphthafuroxan, m.pt. 127° C. 8-Nitro-1-naphthylamine did not yield a furoxan and 2,4-dinitronaphthylamine also failed to give the expected product, the oxidation resulting in a disruption of the ring accompanied by a strong odour of chloropierin. α -Nitroso- β -naphthylamine and β -nitroso- α -naphthylamine both yield the same furazan.—J. F. B.

Quinones; Action of acetaldehyde-ammonia on —. P. C. Ghosh, Chem. Soc. Trans., 1917, 111, 608—612.

WHEN *p*-benzoquinone in nitrobenzene solution is heated with powdered acetaldehyde-ammonia, the mixture suddenly solidifies at 85°—90° C. A deep black substance crystallising in needles is formed which does not melt at 290° C. and is insoluble or only sparingly soluble in the usual solvents. With nitric acid this yields a yellow crystalline nitro-derivative which does not melt at 300° C. The latter is soluble in alcohol and a molecular weight determination indicated the formula $C_{16}H_{12}O_6N_4$, which corresponds to $C_{16}H_{14}O_2N_2$ for the original black compound. This substance, therefore, has an anthracene structure, $O:C_6H_2:NI(CH(CH_3)_2)NI:C_6H_2:O$, but no known anthracene derivative could be isolated from it. With α - and β -naphthaquinones no definite condensation product with acetaldehyde-ammonia could be obtained. Anthraquinone on heating for 6 hours at 220°—225° C. with acetaldehyde-ammonia in a sealed tube, gives a colourless product crystallising in silky needles from alcohol and melting at 281° C. This product contains no nitrogen and gives a phenylhydrazone which does not melt at 300° C. Anthraquinone therefore condenses with acetaldehyde-ammonia in a different manner from benzoquinone, and the product has the constitution

—J. F. B.

IV.—COLOURING MATTERS AND DYES.

Analysis of organic dyestuffs by Formánek's method: Qualitative spectrum —. J. Pokorný. J. Soc. Dyers and Col., 1917, 33, 162—166.

CERTAIN criticisms of Formánek's method for the spectrum analysis of dyestuffs (this J., 1899, 611) are dealt with and several misstatements refuted. Contrary to the statement dealt with by E. J. Muller (Revue, 1903, 71), Aurophosphine G and Brilliant Phosphine 3G may be distinguished spectroscopically (Formánek, Zeit. f. Farb. Ind., 1903, 488). The spectroscopic method of analysis may be carried out readily with a pocket spectro-scope (direct vision with wave length scale). The so-called secondary bands, caused by contrast action, will frequently be noted, and, according to André, can be reproduced on the photographic plate. By fractional extraction with different solvents, mixtures of dyestuffs may be identified. André has stated that when the possibility of chemical action is eliminated, a material influence of the vibrations in dyestuff mixtures does not take place; it is a purely additive action. The suggestion as to the possibility of mobile maxima is erroneously attributed by F. H. Eijdmann and by F. Weigert (Ber., 1916, 1496) to Formánek, who has stated definitely that the maximum intensity of an absorption band retains its constant position at varying concentrations.—F. W. A.

Dyestuffs containing the pyridine ring. W. Harrison. J. Soc. Dyers and Col., 1917, 33, 179—183.

A SUMMARY of known dyestuffs of the pyridine series, obtained by condensing pyridine with cyanogen bromide and coupling with 2 mols. of an aromatic amine, is given, with their melting-points and the colour of the dyeings on silk or fanned cotton. Practically none of these dyestuffs has found application in dyeing or for the sensitising of photographic plates. Of the quinoline dyestuffs, the constitution of Ethyl Red and the sensitising action of the Isocyanines, Orthochrome I, Pinaverdol, and Pinacyanol, and other quinoline derivatives, are discussed. "Azalin" is a mixture of Quinoline Blue and Quinoline Red. Other quinoline derivatives are Quinoline Yellow, and the naphtho- and anthra-quinolines.—F. W. A.

PATENT.

Ortho[hydr]oxyazo dyestuffs: Copper compounds of — and process of making same. B. Wuth and C. Jagerspacher. Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,233,133, July 17, 1917. Date of appl., Oct. 7, 1915.

SEE Eng. Pat. 12,249 of 1915; this J., 1916, 922.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

PATENTS.

Silk fibres: Process for treating —. Kanegafuchi Boseki Kabushiki Kwaisha, Tokyo-Fu, Japan. Eng. Pat. 106,593, May 16, 1917. (Appl. No. 7050 of 1917.) Under Int. Conv., May 16, 1916.

FOR dissolving the sericin and loosening the fibres of silk, the cocoons or silk-waste are treated with the proteolytic enzymes in the juice extracted from the bodies or cocoons of the insects or silk-worms, at 40° C. for 45—60 mins., until the fibres are fully loosened. In the case of waste silk fibres a moderate quantity of the usual scouring reagents may be used for an auxiliary treatment.—J. F. B.

Fabric and coating; Waterproof —. W. H. Adams, Kenyon, R.I. U.S. Pat. 1,231,687, July 3, 1917. Date of appl., Nov. 30, 1915.

A THIN fluid waterproofing composition is made up of viscous hydrocarbon material, wax, and oil dissolved in or softened by a volatile solvent and mixed with a filler of fine cement, insoluble in the volatile solvent but capable of forming colloid substances by the slow action of hygroscopic moisture or carbon dioxide, so as to increase the impermeability and coherence of the composition when spread. A suitable composition comprises a mixture of asphaltum, carnauba wax, ceresin, aluminium oleate, and castor oil in a volatile solvent combined with finely-divided Portland or other hydraulic cement.—J. F. B.

Pulp for paper-making purposes and the like: Method of and apparatus for washing —. S. Milne, Edinburgh. Eng. Pat. 107,410, June 26, 1916. (Appl. No. 8947 of 1916.)

PAPER pulp, particularly pulp produced by the complete disintegration of printed waste papers, is washed on a wire cloth through which sprays of water are directed on the pulp from the opposite side. The principle may be applied to any of the usual pulp-washing devices, such as rotating wire drums or endless wire bands. The preferred type of machine consists of an inclined tray with a wire-cloth bottom subjected to a reciprocating motion in a longitudinal direction. A set of sprinklers is carried on a frame underneath, which is reciprocated at a considerably lower speed than the tray. The pulp is caused to flow from one end of the tray to the other and the sprays of water impinging on the opposite side of the wire float the impurities and keep the meshes of the wire free of deposit.—J. F. B.

Wood and vegetable substances; Apparatus for harvesting the constituents of —, distilling and purifying them. W. K. Freeman, Oswawana, N.Y. U.S. Pat. 1,231,247, June 26, 1917. Date of appl., Aug. 14, 1913.

AN apparatus for extracting soluble matters from wood, etc., comprises a rotary container supported on two cradles in an inclined position, the upper cradle being adjustable to permit proper adjustment of the container; a gear passes around the container and a pinion driven by a motor engages the gear. A fixed hollow shaft passes into the container, and pipes lead from the exterior of the shaft and discharge into the container; a strainer is provided on the hollow shaft and pipes leading from the hollow shaft to the exterior of the shaft through which fluids may be passed into the container through the strainer and through the shaft to the exterior again while the container is rotating.—J. F. B.

Paper; Manufacture [sizing] of —. C. W. Fish, Rawcliffe, Yorks. Eng. Pat. 107,820, July 13, 1916. (Appl. No. 9898 of 1916.)

ONE or more colloid substances or substances capable of producing colloids is mixed with the pulp containing the size and colour, and nitre cake or sodium bisulphate is added. For instance, a pulp sized with 8% of a 30% sodium resinate size is treated with about 5% of a mixture of china clay and colloidal starch, sodium aluminate, aluminium silicate or the like with nitre cake.

—J. F. B.

Fourdrinier [paper] machine. A. J. Davies, Kenogami, Quebec, Canada. U.S. Pat. 1,231,717, July 3, 1917. Date of appl. June 26, 1916.

IN a paper machine of the Fourdrinier type, a suction box is provided with a vertically oscillatory support with adjustable means for imparting limited motions to the box and for guiding these motions.

—J. F. B.

Paper; Method of and means for drying —. A. H. White, Brooklyn, N.Y., Assignor to International Paper Co., New York. U.S. Pat. 1,232,141, July 3, 1917. Date of appl. May 29, 1915.

IN machines where the web of paper passes over a series of drying cylinders, a blast of air is directed against the paper, in the pocket formed between two adjacent cylinders, at the point where the web leaves the first cylinder and in a direction contrary to the travel of the paper. The air becomes laden with moisture and tends to flow laterally towards the cylinder on to which the paper passes after completing the loop, and is drawn away by suction operating near this second cylinder, also in a direction contrary to the travel of the paper.

Process for converting cellulose into glucose. Eng. Pat. 107,219. See XVII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Laundering; Conservation of garments in —. H. G. Elledge. Sci. Amer. Suppl., July 14, 1917.

PRELIMINARY treatment with kerosene containing 1% of oleic acid followed by wringing in a centrifuge is recommended for the removal of grease stains. Soap and sodium carbonate, in addition to their detergent properties, apparently tend to conserve the strength of the fabrics; a similar function is attributed to the centrifugal extractor employed in laundries as compared with domestic washing. The effect of exposure to sunlight and of smoke in air-drying is considerable. The mechanical wear in washing is reduced by the use of a thick lather. Soap solution at 40°C. has a bactericidal efficiency of 98% for all the common pathogens, and the subsequent laundering processes have been proved to effect sterilisation.

—F. W. A.

Lamp for exposing patterns; A new [marble] —. A. Ganswindt. Deutsche Färber-Zeit., 1917, 53, 49. Chem.-Zeit., 1917, 41, Rep., 219.

THE marble lamp ("Marmorlicht") of Engel (Ger. Pats. 265,027 and 267,065; see this Journal, 1913, 87; 1914, 137) has thin plates of marble, alabaster, etc., the transparency of which has been increased by immersion in a solution of resin or of a cellulose preparation, such as shellac or celluloid. It has been found cheaper to use thicker marble plates polished on both sides and soaked at a high pressure and temperature in

non-volatile hydrocarbons; the necessity for enclosing the marble plates in glass is thus avoided. Photometric measurements showed that such marble is more transparent than ground glass. A further advantage is the fact that the marble plates are equally illuminated up to the edge, whereas with ground glass the luminosity decreases greatly towards the edges. In spite of its high transparency, marble absorbs the dark heat rays to a degree not hitherto attained.—F. W. A.

PATENT.

Dyeing [with sea-weed]. N. Malcolmson and H. H. Kelsey, London. Eng. Pat. 107,005, Apr. 5, 1916. (Appl. No. 4986 of 1916.)

THE material to be dyed is placed in a bath of water or spirit containing in the raw state or in paste or powder a sea-weed of the Rhodospirum, Chlorospirum, or Melanosperm group, to which sulphuric acid may be added to intensify or vary the colour imparted to the material. The use of dulce (Eng. Pats. 142 of 1881 and 1789 of 1902) and of laminaria powder in indigo paste (Eng. Pat. 1789 of 1902) is not claimed.—F. W. A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Rapid determination of the strength of —. H. D. Richmond and J. E. Merreywether. Analyst, 1917, 42, 273—274.

FOUR hundred grms. of water at 18°C. is measured into a vacuum-jacketed flask, provided with a stirrer and with a thermometer reading to 0.01°C. The temperature soon becomes constant and is read off; 5 c.c. of the sample is then pipetted in, allowing the pipette to drain for 15 secs., and the mixture is stirred until the temperature is again constant. The water equivalent of the calorimeter used by the authors was found to be 14.5 grms., and the volume of sulphuric acid delivered by a 5 c.c. pipette 4.911 c.c. From these data and from the results recorded by Pickering (Chem. Soc. Trans., 1890, 57, 64) the following formula was calculated:—% $H_2SO_4 = 100 - 7.6 (3.994 - R)$ where R is the rise in temperature. The results obtained agree with those found by titration. (See also Howard, this J., 1910, 3.)—W. P. S.

Potash from felspar. D. J. Benham. Canadian Chem. J., May, 1917. Met. and Chem. Eng., 1917, 16, 701—705.

A MIXTURE (110 tons) of felspar, coal, calcium chloride, and limestone is heated to a high temperature in a blast furnace, the limestone being used to give a fluid slag. A certain percentage of the potash is volatilised at about 900°C., but the reaction is not complete until a temperature of about 1600°C. is reached. The volatilised potassium chloride passes into a condenser, where it meets a current of steam; the chloride dissolves in the condensed water, and is obtained in a high state of purity by evaporation and crystallisation, over 90% of the potash content of the felspar being recovered. A satisfactory process for obtaining sodium compounds from the vapour has also been developed. The slag is converted into sewer-pipe, tile, and paving brick, and has a peculiar porcelain-like surface. It is stated to be possible to adapt the process to utilise cement marl instead of felspar, and either rotary kilns or blast furnaces of a certain type may be employed for volatilising the potassium chloride.

—B. N.

Polash from cement at the works of the Riverside Portland Cement Co. J. Treanor. Met. and Chem. Eng., 1917, 16, 701—703.

CLAYS and shales suitable for the manufacture of Portland cement vary in K_2O content up to 2.5%; about 40 to 50% of the total leaves the kiln with the kiln dust, and about 80% of this may be recovered by electrical precipitation, the dust collected containing from 4 to 10% of potash, usually water-soluble. By keeping the mixture at a minimum temperature of 85° C. during leaching and filtration, and maintaining proper conditions of concentration, the formation of an insoluble double sulphate of calcium and potassium may be prevented, and the whole of the potash may be recovered. A process has also been developed for obtaining a better volatilisation of potash from the clinker, by adding 0.8% of calcium fluoride for every 1% of K_2O . Potassium fluoride, which is easily volatilised, is formed, but is reconverted by the oxides of sulphur in the combustion gases into potassium sulphate, with the liberation of hydrofluoric acid. The latter is neutralised by the calcium compounds present in the dust, re-forming calcium fluoride, and, after leaching, the filter cake containing the calcium fluoride is returned to the kiln for further use. In this way 90% of the potash in the raw mixture may be volatilised, and 80% of the volatilised potash is caught by the dust collectors, the yield being further reduced, however, by about 5% in the leaching process. —B. N.

Purification of salts [e.g., ammonium nitrate] by "clairage," or by fractional crystallisation. E. Rengade. Comptes rend., 1917, 165, 237—240.

"CLAIRAGE" is the name given to the displacement by pure water or other solvent of the mother liquor from the crystals. The name may also be applied to the process of purifying a mixture of a soluble salt and some equally soluble impurity by washing with a solvent at a low temperature. The method of purifying salts by fractional crystallisation is the exact reverse of "clairage," but when the equilibrium between solvent and salts is the same and the final temperature is also the same, the same final results will be obtained. The author examines the theory of purification by "clairage" as typical of both methods, and takes the more general case in practical work, namely, the purification of a salt containing a different base and a different acidic ion from the impurity, when the salts may react by double decomposition and yield two other salts, so that the problem is one of the equilibrium between four salts in solution. As an illustration the author takes the case of ammonium nitrate mixed with a small quantity of sodium chloride, and examines what will occur when this mixed salt is treated with a very small quantity of water at first, gradually increasing this until only pure ammonium nitrate remains. If the initial quantity of water added be sufficiently small, the composition of the solution produced will be the same at a given temperature, and will be a function of that temperature, whatever may have been the proportions of the original salt mixture. To determine which of the four salts possible will remain, a drop of the liquid to be used for "clairage" was placed upon a microscope slide, and the four salts projected into it successively; ammonium nitrate, sodium nitrate, and ammonium chloride remained unaltered, whilst the sodium chloride was immediately decomposed, the distinctive crystals of ammonium chloride being rapidly formed. Therefore when a mixture of ammonium nitrate and sodium chloride is treated with a small quantity of water at the ordinary temperature, the sodium chloride will be completely replaced by sodium nitrate and ammonium

chloride. If the quantity of water be increased progressively, the ammonium nitrate, sodium nitrate, and ammonium chloride will dissolve simultaneously, the second in larger proportion than the third, but the composition of the liquid will remain constant until all the sodium nitrate has dissolved and there remains only a mixture of ammonium nitrate and ammonium chloride. At this point, supposing all the original solution to have been removed, a new equilibrium will be established, with a solution of constant composition corresponding to the simultaneous solubilities of the two salts, until the point is reached (the treatment being continued) when the ammonium chloride is completely dissolved, and the ammonium nitrate remains alone in a state of purity. Thus the purification is effected in two stages, and in order to determine the quantity of water necessary to purify completely a given mixture at a particular temperature, it is sufficient to ascertain by analysis the composition of the two saturated solutions corresponding to these stages.—J. B. C. K.

Iron sulphide; Electrolytic valuation of —. H. Williams. Chem. News, 1917, 116, 13—14.

IRON sulphide is used in chemical works for removing arsenic and other metals of the same group from commercial mineral acids, and as its value for this purpose depends upon the amount of monosulphide it contains, the oxidation methods of determining the sulphur contents are inapplicable for its valuation. The author has found that the amount of monosulphide can be most accurately determined by precipitating cadmium sulphide from a solution of a cadmium salt by the hydrogen sulphide evolved when the iron sulphide is treated with hydrochloric acid and zinc. The cadmium sulphide is converted into chloride and then into hydroxide, which is dissolved in potassium cyanide solution and the cadmium deposited electrolytically on a rotating cathode.—J. B. C. K.

Chlorine and hydrogen; Temperature coefficients of photochemical action on mixtures of — in monochromatic light. M. Padoa and C. Butironi. Gazz. Chim. Ital., 1917, 47, 11, 6—9.

THE intensity of photochemical action on a mixture of chlorine and hydrogen prepared electrolytically from hydrochloric acid was measured by determining the contraction in volume after exposure at definite temperatures in white, ultra-violet, and coloured light. According to Bevan (Proc. Camb. Phil. Soc., 12, 398) the temperature coefficient for an interval of 10° C. in the case of a mixture exposed to white light is 1.21. In the authors' determinations the following coefficients were obtained:—In white light, 1.29; green light (nickel sulphate solution screen), 1.50; blue light (copper sulphate screen), 1.31; violet light (methyl violet solution screen), 1.21; and ultra-violet light (mercury vapour lamp with nitrosodimethylaniline solution screen), 1.17.—C. PATENTS.

Nitric acid, hydrochloric acid, and like gases; Condensation, absorption, or other chemical treatment of — A. E. Charles and F. J. Lancaster, Kingston-upon-Hull. Eng. Pat. 107,255, June 28, 1916. (Appl. No. 9088 of 1916.)

HOLLOW cylindrical units are arranged one on top of another to form a tower, the bottom unit being connected to the gas inlet, and the top to the outlet. The top of each unit except the uppermost is increased in diameter to form a rim which serves as a seat for the bottom of the unit next above, an acid-tight joint being made by means of putty or the like. Each of the units intermediate between the top and the bottom is provided with a series of separate cooling or heating pipes; each pipe projects through opposite sides of the unit and delivers water (or heated oil) into the open upturned end of the pipe next below. The intermediate units have each a perforated bottom on which suitable packing is placed. The holes through which the cooling (or heating) pipes pass through the wall of a unit are each made of two diameters, that portion of the hole which is of larger diameter providing a space round the pipe which is filled in with suitable putty so as to make a tight joint between the pipe and the reduced portion of the hole. A tapered groove extends downwards at an angle from the bottom of the hole through which a pipe passes, and there is an annular groove in the inside of the wall of the unit, connected with the tapered groove, by which means any acid settling on the inside of the tower, or flowing back on the underside of the cooling pipes, is caused to flow in streams down the inside of the tower.—T. H. B.

Hydrochloric acid; Production of — E. C. R. Marks, London. From Tentelev Chemical Works, Ltd., Petrograd. Eng. Pat. 107,312, Sept. 21, 1916. (Appl. No. 13,431 of 1916.)

PURE hydrochloric acid is obtained by distilling the commercial acid in the presence of a concentrated solution of zinc chloride of such strength that it may be heated to 125° to 135° C. The operation is continuous, crude acid being introduced in quantity equivalent to the pure acid obtained.

—T. H. B.

Acetic acid; Manufacture of — H. Wade, London. From Holzverkohlungs-Ind. A.-G., Konstanz, Germany. Eng. Pat. 107,606, Apr. 26, 1916. (Appl. No. 6010 of 1916.)

FORMIC acid and empyreumatic substances are removed from acetic acid by distilling a mixture of about equal parts of the latter and 70% sulphuric acid, the temperature of the mixture being maintained at about 130° C. Further quantities of crude acid are added, corresponding to the amount of acetic acid distilled off. A sufficient proportion of water must be maintained to prevent destruction of the acetic acid; concentrated aqueous solutions of soluble sulphates may be used as a diluting agent instead of water. At the temperature employed, formic acid is destroyed, but acetic acid is not affected. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 28,595 of 1902; this J., 1903, 291.)—T. H. B.

Zinc sulphide; Process for oxidising — C. J. G. Aarts, Dongen, Holland. Eng. Pat. 101,978, Oct. 26, 1916. (Appl. No. 15,260 of 1916.) Under Int. Conv., Oct. 26, 1915.

ZINC sulphide is oxidised to sulphate by heating it with oxygen or gases containing oxygen, under pressure higher than that of the atmosphere.

—T. H. B.

Strontium sulphate; Treatment of impure — A. A. Roberts, London. Eng. Pat. 107,324, Oct. 30, 1916. (Appl. No. 15,447 of 1916.)

IMPURE strontium sulphate—e.g., the waste obtained from the treatment of ground strontium sulphate spar on vanning tables—is lixiviated, dried, and re-ground. It is then agitated with strong commercial hydrochloric acid at about 110° C. The impurities are thus dissolved, and a subsequent thorough washing of the paste leaves it quite white and neutral, and ready, when elutriated, for use as a pigment. The acid vapours given off during the solution process may be utilised by passing them over heated strontianite or strontium carbonate to produce strontium chloride; or the vapours may be condensed and the aqueous acid used in a similar manner, or for the purification of a further quantity of strontium sulphate.—E. W. L.

Cyanogen compounds; Production of — A. R. Lindblad, Ludvika, Sweden. Eng. Pat. 107,426, June 29, 1916. (Appl. 9183 of 1916.)

AN alkali silicate is heated in an electric furnace, with carbon and lime, and exposed to the action of nitrogen while heated to such a temperature that cyanogen compounds are formed. The lime is added in such quantity that the slag formed will be suitable for cement making. The cyanogen compounds are led off from the furnace with other gaseous products. The addition of lime increases the yield of cyanide.—T. H. B.

Silicates; Treatment of — A. H. Cowles, Searan, N.J., U.S.A. Eng. Pat. 107,640, July 4, 1916. (Appl. No. 9418 of 1916.)

LEUCITE, felspar, or a similar silicate, is heated with a calcium compound such as the oxide, to a temperature which may be below the fusing point, but is sufficiently high to drive off approximately all the carbon dioxide, and cause chemical reaction between the constituents of the mixture. The proportions are such that the product contains two molecules of alkaline-earth oxide to one molecule of silica, and less than two molecules, but at least one, of alkali oxide to one molecule of alumina. Soluble alkali compounds and alumina are separated from the mass by leaching; at least 85% of the alumina may be thus recovered.—T. H. B.

Hydrogen, pure Glauber salts, and a gas purifying mass; Production of — from iron scrap and bisulphate of soda. P. Becquevort, Folkestone, and C. Deguide, Pas-de-Calais, France. Eng. Pat. 107,807, July 11, 1916. (Appl. No. 9747 of 1916.)

A SOLUTION of sodium bisulphate of density 20° B. (sp. gr. 1.16) is added to scrap iron in a suitable tank and heated by steam to 90° C. The liberated hydrogen is washed and collected in a holder. The resulting solution of ferrous and sodium sulphates is treated with an excess of powdered lime, producing a mixture of calcium sulphate and ferrous hydroxide, which is aerated to convert the latter into ferric hydroxide. The mass is filter-pressed, and the solution flowing away is concentrated to 30° B. (sp. gr. 1.26) and Glauber's salt separated by crystallisation. The material left in the filter-press is used as a gas-purifying agent.—T. H. B.

Aluminium nitride; Process of manufacture of — O. Serpek, Assignor to Soc. Gén. des Nitrures, Paris. U.S. Pat. 1,233,925, July 17, 1917. Date of appl., Aug. 12, 1915.

SEE Eng. Pat. 11,271 of 1915; this J., 1916, 115.

Aluminium nitride; Process for the manufacture of—O. Serpek, Assignor to Soc. Gén. des Nitrures. Paris. U.S. Pat. 1,233,926, July 17, 1917. Date of appl., Aug. 1, 1916.

SEE Eng. Pat. 101,091 of 1916; this J., 1917, 503.

VIII.—GLASS; CERAMICS.

PATENTS.

Furnaces for melting glass or other materials. L. Grote and A. W. H. Vivian, London. Eng. Pat. 107,211, Apr. 19, 1916. (Appl. No. 5735 of 1916.)

A RECTANGULAR furnace with one crescent-shaped end and the fires or burners at the opposite end, is provided with an outlet flue at each side, close to the junction of the sides and the rounded end of the furnace, one outlet being in a higher plane than the other. It is stated that the furnace gases travel straight forward until they reach the end of the straight sides of the kiln, after which they assume a cyclonic path and pass away through the outlet on the opposite side of the furnace to that along which they first travel.—A. B. S.

Drying china clay. T. M. Stocker, St. Austell. Eng. Pat. 107,866. (Appl. Nos. 12,368, Aug. 31, and 16,198, Nov. 11, 1916.)

THE clay is laid on a floor below which are longitudinal flues communicating with a chimney. Fireplaces are erected at one end of the drying floor, and the products of combustion pass through the flues under the floor to the chimney. The hot moist air rising from the clay is drawn off, and used in the combustion of the fuel, whereas in ordinary dryers of this type it remains in the drying chamber and hinders rapid and economical drying.—A. B. S.

Kilns or ovens for firing bricks, tiles, pipes, china, and such like ceramic ware. T. West, Durham, and W. I. G. Lewis, Tamworth. Eng. Pat. 107,678, July 28, 1916. (Appl. No. 10,688 of 1916.)

BENEATH the perforated floor of a round or rectangular up-draught kiln, flues are arranged so as to leave as open a space as possible in which the fire gases may circulate. In the case of a round kiln, for example, two annular flues are provided, connected by cross flues with each other and with segmental spaces between the double walls of the kiln. The products of combustion from the fires are discharged directly into the top of these segmental spaces and pass down them into the annular flues and up through the perforated floor of the kiln. In the case of a rectangular kiln with fires at each end, the products of combustion are passed through two or more downcast flues into an equal number of flues beneath the floor which run the whole length of the kiln and discharge their contents through the perforated floor above them.—A. B. S.

Enamels; Production of—J. E. Pollak, London. From R. Koepp und Co., Oestrich, Germany. Eng. Pat. 107,392, Mar. 28, 1916. (Appl. No. 4571 of 1916.)

THE addition of cobalt, nickel, manganese, copper, and some other oxides to an enamel greatly increases its adhesion. Cobalt oxide is the best, but is expensive. Nickel oxide is good, and much cheaper. Manganese and copper oxides are not satisfactory alone. It has, however, been found that cobalt ores containing (say) 23% manganese oxide, 4% cobalt oxide, and 2.6% nickel oxide may be used satisfactorily and much more cheaply than pure cobalt and nickel oxides. The ores

used for this purpose should be free from sulphur and arsenic; iron oxide is no detriment. The mixture, whilst excellent for groundwork, is almost useless for colouring the surface of enamels.

—A. B. S.

Magnetic separators. Eng. Pat. 107,281, See I.

IX.—BUILDING MATERIALS.

Silica; The refractory properties of—H. Le Chatelier and B. Bogitch. Comptes rend., 1917, 165, 218—224.

THE reputed melting point of kaolin (1700° C.) is the same as that of silica, but is really the temperature at which the clay can just sustain a load of about 1 gram. per sq. cm. If the material is loaded with 10 kilos. per sq. cm., its melting point will be 400° C. lower. Silica, on the contrary, has a true melting point which is independent of the pressure, and shows no appreciable softening. The pressure required to crush an article made of silica decreases progressively with increased temperature as shown by the following results on a "Star" (U.S.A.) silica brick: 15° C., 170 kilos. per sq. cm.; 520°, 158; 670°, 150; 800°, 139; 950°, 125; 1050°, 120; 1200°, 85; 1320°, 62; 1460°, 50; 1540°, 37; and 1600° C., 30 kilos. per sq. cm. On extrapolating these figures to 1700° C. (the normal temperature of the arches of steel furnaces), the crushing strength of the bricks would only be 12 kilos. per sq. cm., but as this is about ten times the pressure of the superincumbent brickwork, the stability of the bricks in the arches is assured. This mechanical strength at high temperatures is a special characteristic of silica bricks; it is not possessed by clay or magnesia bricks, though magnesia has a higher melting point than silica. In a silica brick the silica forms a continuous network the pores of which are penetrated by the molten silicates without affecting the strength of the brick. The formation of this network by the recrystallisation of the silica is due to the different solubilities of the various forms of silica, quartz crystallising from the molten magma first as cristobalite and later as tridymite. The quality of silica bricks depends primarily on the development of a satisfactory network by careful control of the proportion of fluxes, the temperature of the bricks when in use, the formation of the network, and its eventual destruction. Several bricks which gave excellent results in use were found to contain 3—5% metallic oxides corresponding to 8—14% sulphates, the ratio of the oxides to sulphates averaging 35:100. This ratio may be determined with fair rapidity and is characteristic of satisfactory silica bricks. The temperature at which the bricks should be burned depends on the purpose for which they are to be used. For lining steel furnaces, a burning temperature of 1700° C. is desirable. For the distillation of oil, on the contrary, a much lower burning temperature will suffice and the bricks may contain twice the amount of metallic oxides mentioned above.

The formation of the network is the most delicate part of the manufacture of silica bricks. It requires a prolonged heating at about 1150° C. for several days, the rate of formation being most rapid when the grains of quartz in the brick are extremely minute. A sufficiency of larger grains must be present, however, in order to prevent the formation of the minute fissures which are produced when the material is composed wholly of fine grains.

When the bricks in use are heated rapidly to the temperature at which any unconverted quartz grains are inverted, the expansion which accompanies this change of form breaks the network and lessens the strength of the bricks. Moreover, the pressure of the brickwork in an arch opposes any

lateral expansion and produces spalling, which is one of the worst defects of badly-made silica bricks. In a well-burned brick, an expansion also occurs at the moment when larger grains of quartz are inverted to cristobalite, but its effect is less serious, as these grains are able to expand in all directions, and it occurs sufficiently slowly for the network to be reformed at the point where it has been damaged. Nevertheless, this phenomenon notably reduces the strength of the bricks. The results of determinations of the sulphate equivalent of the oxides, true and apparent sq. gr., and the crushing strength at 1600° C. after sixty re-heatings showed clearly that good silica bricks, after heating for 1 hour at 1600° C., have a crushing strength of at least 10 kilos. per sq. cm. A prolongation of the heating at this temperature reduces the crushing strength of well-fired bricks, but increases that of underburned ones.—A. B. S.

Silica bricks. H. Le Chatelier. *Rev. Mét.*, 1917, 14, 74—83.

THE chief phenomenon concerned in the manufacture and use of silica bricks is the transformation of quartz into two other forms of silica—cristobalite and tridymite. This transformation is

accompanied by a recrystallisation which makes the bricks very strong at high temperatures, and by an expansion, which causes an increase in the porosity and a loss in the strength of the bricks, and may result in their destruction. The various forms of silica may be divided into two groups according to the accuracy with which their chief characteristics have been established.

GROUP I.

Variety.	Symmetry.	Specific gravity.	Inversion point.
Quartz	Ternary	2.65	570° C.
Cristobalite	Quadratic	2.33	225° C.
Tridymite	Orthorhombic	2.27	117° and 674° C.
Vitreous silica ("fused silica")	Amorphous	2.22	—

GROUP II: Chalcedony; hydrated silica; calcined precipitated silica. The ratio of expansion to temperature for each of these materials is shown in the figure. At 1000° C., tridymite, cristobalite, and fused silica all have approximately the same specific gravity, viz., 2.20.

Formation of cristobalite. A specimen of "quinqet" (aluminous) glass examined by the author (this J., 1916, 837) contained irregular spherulites of cristobalite, 1—3 mm. in diameter, formed at 800° C. Arch bricks obtained during the demolition of old glass furnaces showed a superficial

fusion due to the action of sublimed alkali. Cristobalite crystals occur in part of this semi-fused material, these crystals also containing a large number of minute tridymite crystals which show under the microscope as granulations. Silica bricks made with more than the usual proportion of flux, when burned at 1700° C., form a glassy mass which unites the grains of sand, becomes saturated with silica from the latter, and slowly recrystallises on cooling. The crystals thus formed on the surface of the sand-grains are transformed by the heat into cristobalite. The abundance of these crystals shows that with suitable proportions of flux, the sand-grains would be united with a crystalline bond and to this the bricks owe their strength. Cristobalite also occurs in furnace linings composed of ganister and clay, and containing about 10% of metallic oxides. The most characteristic specimens are those taken from just below the superficial ferruginous crust in Bessemer converters in a region where the amount of re-heating is considerable and the cooling is rapid. The author concludes that in all cases where silica crystallises rapidly from a glass, it is in the form of cristobalite. The grains of quartz which are directly inverted into cristobalite are best recognised by their peculiar appearance—that of a mass of very small spheres—caused by fissures due to the sudden reduction in volume (about 1% linear shrinkage, at the transformation point (225° C.). These fissures reduce the strength of silica bricks; they may be lessened by cooling very slowly or increased by rapid heating to 500° C., followed by rapid cooling.

Formation of tridymite. Though cristobalite is more stable than quartz, it is less so than tridymite and is gradually inverted into the latter under the same conditions as those favourable to the inversion of quartz into cristobalite, though a longer time is required. In the customary burning of silica bricks a small proportion of tridymite is produced; its amount is increased on each subsequent heating; inversion to tridymite is complete in bricks which have been long in use in some steel furnaces. The rate of formation of tridymite is about one-hundredth of that of cristobalite.

Conditions of stability of tridymite. At temperatures above 1000° C., cristobalite is metastable and under some conditions is the most stable crystalline form of silica. Fenner's conclusion (*Amer. J. Sci.*, 1913, 36, 383; this J., 1913, 22) that tridymite only constitutes the stable phase up to 1480° C. and above this temperature and up to its fusion point (1780° C.), cristobalite is the stable phase, is opposed to those reached by the author. The latter found that bricks obtained from steel furnaces, where the temperature is much above 1480° C., contained tridymite, and he suggests that Fenner's conclusions are based on insufficient evidence. The author heated a piece of silica brick consisting wholly of tridymite to 1700° C., but whilst, according to Fenner, it might be expected that it would be converted into cristobalite, actually no change occurred. An examination of part of the arch of a Martin's steel furnace showed the same thing, the crystals of tridymite being present in material which must have been heated to 1750°—1800° C. Hence tridymite is the only crystalline form of silica which is perfectly stable at high temperatures.—A. B. S.

Polash from cement. Treanor. See VII.

PATENTS.

Furnaces or kilns for roasting cement, magnesia etc. B. E. D. Kilburn, London. From Beocor Cementgyári Ünio Részvenytársaság, Budapest Hungary. Eng. Pat. 107,209, Apr. 6, 1916 (Appl. No. 5075 of 1916.)

A VERTICAL shaft is fitted with a movable grate

provided with toothed or crushing bars. The grate may consist of a horizontal slotted disc, with radial, toothed bars, rotated by means of a pulley on the vertical shaft below the grate, or the grate-bars may form part of an endless chain conveyor, underneath which a screw conveyor is fitted at right-angles so as to remove the material which has passed between the bars. In another modification the bars are placed longitudinally on the periphery of a conical drum, the central shaft in which is mounted obliquely, so that the bars immediately below the shaft are in a horizontal position, the material falling through them passing to the ground beneath the drum or out through the wider end of it.—A. B. S.

Fire-resisting composition and its application to the moulding of boards, sheets, and flooring blocks, and as a covering for walls, roofs, and floors. R. Y. Ardagh, Hove. Eng. Pat. 107,402, June 14, 1916. (Appl. No. 8400 of 1916.)

COCONUT shell is ground in a disintegrator to the size of coarse oatmeal. The short fibre is passed through a sieve and is then mixed with an equal bulk of magnesite in the dry state, and the mixture is made plastic or even liquid by adding magnesium chloride solution. The composition readily adheres to soft wood, but harder woods require to be grooved, or corrugated paper or felt may be glued to them. It may be moulded on corrugated paper and then sawn into blocks or boards. (Reference is directed, in pursuance of Sect. 7 Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 17,908 of 1898.)—A. B. S.

Road surfaces composed of mineral aggregates and bituminous binders; Construction of— H. Rorke, Kingston Hill, Surrey, legal representative of E. Rorke. Eng. Pat. 107,483, Sept. 20, 1916. (Appl. No. 13,337 of 1916.)

THE stone or other mineral aggregate is divided into two sizes, the larger size (over $\frac{1}{4}$ in. diameter) being coated with pitch, and the smaller size (less than $\frac{1}{4}$ in. diameter) with bitumen. The two coated materials may then be effectually mixed at a suitable temperature so that they may be laid on the road as one coat, the larger material automatically taking the lower position, and the finer material filling the interstices and forming a close surface coating during the subsequent operations of spreading, rolling, and beating the road. The proportion of each binder required depends on the nature and size of the mineral aggregate used.

—A. B. S.

Plastic composition for use in the manufacture of mouldings. F. J. Tomalin, Northampton. Eng. Pat. 107,557, Mar. 21, 1917. (Appl. No. 4108 of 1917.)

ABOUT 40 lb. of whiting is mixed with water, the mixture is left until sufficient water has evaporated to convert it into a stiff paste, and then 30 lb. of glue or size, previously melted in a hot-water-jacketed vessel, is added. About 1 pint of turps and $\frac{1}{2}$ lb. of stearin wax are added to the mixture, and the whole is thoroughly stirred; 5—10 lb. of taster of Paris or Keene's cement made into a thick paste with turps is then added to give the composition the required degree of firmness. The composition is placed in a hot-water-jacketed vessel, and when thoroughly mixed it is fed to the moulding machine.—A. B. S.

Bituminous cements. E. W. Pattison, Manchester. From T. Moniwa, Akasaka, Japan. Eng. Pat. 107,613, June 1, 1916. (Appl. No. 7756 of 1916.)

TO avoid the staining of glazed bricks, etc., laid in ordinary cement, and to provide a cement applicable to materials with smooth and non-absorbent surfaces, a cement is used consisting of bitumen

20—25%, asphaltine 14—17%, quartz, asbestos, and the like 66—58%. The coefficient of expansion of this cement may be made the same as that of the materials to be united by varying the proportion of quartz or silica. For use, the cement is melted and then applied thinly to the surfaces to be united.—A. B. S.

Cementing material and manufacture of compositions therefrom. T. D. Kelly, Hove. Eng. Pat. 107,951, Apr. 21, 1917. (Appl. No. 5612 of 1917.)

A TOUGH cementing material, proof against extremes of heat and cold, water, oil, and acids, is made by mixing 5—10 parts of an adhesive oxidised or polymerised oil, 5—30 parts of water glass, and 100—300 parts of Portland cement. To this mixture, while plastic, 500—1000 measures of any filling material which is not of a greasy or oily nature may be added, and the whole compressed in moulds or by means of rollers. The setting of the material is accelerated by heat; it neither expands nor contracts after heating to 2000° F. (about 1096° C.) for six hours, and is as waterproof and as hard after such heating as before.—A. B. S.

Cement; Acid-proof— R. Haddan, London. From Electro-Chemical Supply and Engineering Co., Philadelphia, U.S.A. Eng. Pat. 108,278, Mar. 26, 1917. (Appl. No. 4360 of 1917.)

SEE U.S. Pat. 1,220,575 of 1917; this J., 1917, 504. The composition from which the cement is made contains apatite or pure calcium phosphate in addition to silicious material and sodium silicate.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steel; Quenching of— H. Le Chatelier. Comptes rend., 1917, 165, 172—174.

THE author points out the confirmation that A. Le Chatelier's theory of the transformation of the iron-carbon alloys (Bull. Soc. d'Encour., 1895, 1340) receives from recent experimental work, viz., that of Portevin (this J., 1917, 720) and Dejean (see below) by thermal methods, and Chevenard (this J., 1917, 881) by dilatation measurements. Martensite is regarded as a solid solution of carbon in α -iron. Pearlite is the product of resolution of austenite whereas troostite is the form of the mixture of cementite and ferrite as produced by the resolution of martensite.—H. J. H.

Iron; Carburisation of—by cyanides and cyanates. Portevin. Comptes rend., 1917, 165, 180—182.

WHEN iron is case-hardened by heating at 806°—900° C. in presence of cyanides or ferrocyanides, cyanates are always present. The effect of the cyanates was studied in the carburising of iron wires (C=0.03—0.08%, Mn=0.41%) in which mixtures of potassium cyanide and cyanate in different proportions were used. It appeared that cyanates were necessary to rapid carburisation, and the best results were obtained when 25—40% of cyanate was present in the mixture used. This is perhaps the reason for the inclusion of oxidising agents (potassium nitrate or bichromate) in case-hardening mixtures.—H. J. H.

Troostite and martensite; Formation of— P. Dejean. Comptes rend., 1917, 165, 182—185.

DIFFERENTIAL cooling curves for a steel (W=18%, Cr=4%) are given showing the influence of the initial temperature in the transformations. When the initial temperature varies from 850° to 900° C., a transformation (A) occurs between

700° and 800° C.; with initial temperatures above 900° a second transformation (B) appears just above 400°, while the first point disappears if cooling begins from temperatures above 980° C. Steels which have shown the point A are pearlitic or troostitic; those which have shown B are martensitic and those showing A and B together both troostitic and martensitic. It is concluded that A marks a resolution of austenite to pearlite or troostite. In the latter case, part of the carbon remains in solid solution in residual austenite which is resolved at a lower temperature into martensite. There is a marked discontinuity between the points at which troostite and martensite appear, but none between those at which troostite and pearlite are formed. To suppress the formation of troostite and obtain martensite alone it is necessary to start from an initial temperature which increases as the rate of cooling is diminished.

—H. J. H.

Manganese and chromium: Rapid determination of— in metallurgical products. Travers. *Comptes rend.*, 1917, 165, 187—189.

IN the estimation of manganese as permanganate by oxidation with ammonium persulphate in presence of silver nitrate, the solution should not be boiled after addition of the reagents, otherwise low results will be obtained, possibly by the reduction of permanganate by hydrogen peroxide formed from the persulphate. The permanganate is titrated with sodium arsenite solution, the latter being added to the former, except when small volumes are used, as in back titrations. Details of analysis are as follows:—0.2 gm. of carbon steel is dissolved in 20 c.c. of nitric acid (sp. gr. 1.1) and 30 c.c. of cold water is added so as to bring the temperature to 40—50° C.; 5 c.c. of N 10 silver nitrate and 1 to 1.5 c.c. of saturated solution of ammonium persulphate are added and the mixture shaken. Three minutes after the appearance of the violet colour, the mixture is poured into 100 c.c. of cold water and titrated at once with sodium arsenite until the colour is discharged. If the Mn content is greater than 0.5%, a greenish-yellow colour is produced. The arsenite solution should contain 0.650 gm. of As_2O_3 per litre, when 1 c.c. = 0.0002 gm. Mn or 0.1% Mn on the sample. Titrating at a temperature below 36° C. no appreciable re-oxidation of manganese occurs. With suitable modifications the method can be applied to chrome, tungsten, vanadium, and molybdenum steels, also to cast iron, iron and manganese ores, slags, brasses, and bronzes. In chrome steels, the chromium can be determined by titration with the same sodium arsenite solution, of the sample dissolved in nitric acid of sufficient concentration (20 c.c. of nitric acid of 36° B. per 100 c.c. of solution). Unlike ferrous solutions and titanous chloride, sodium arsenite is stable and does not reduce vanadium which often accompanies chromium in steels.—H. J. H.

[Copper ore] tailings; Ammonia leaching of Calumet— C. H. Benedict. *Eng. and Min. J.*, 1917, 104, 43—48.

A 2000-ton leaching plant is in operation for treating the tailings from the Calumet and Hecla Mining Co.'s mills. The principle of the process consists in dissolving the native copper in ammonium carbonate in presence of air; the cupric salt formed dissolves more copper, forming a cuprous salt which oxidises rapidly and is thus capable of dissolving more metal. The resulting solution is distilled with steam, the ammonia and carbon dioxide being recovered; the copper oxide is precipitated as a heavy powder which is smelted along with the native copper concentrates. The mill tailing is passed through settling tanks and classifiers, the slimes from which are wasted at

present. The sand is treated with ammonia solution by percolation in eight steel tanks 54 ft. in diameter and 12 ft. high, with water-sealed covers and filter bottoms of wood grating covered with coco matting and duck. The leaching liquors are oxidised by blowing air through them, the ammonia given up being absorbed in a wash solution. The time taken for leaching is 90 hours. The stills consist of superimposed cylindrical sections fitted with a central vertical shaft carrying a scraper for each section, to prevent adhesion of scale. 90% of the copper is recovered in two "roughing" stills connected in parallel, and the remaining 10% in a finishing still from which the spent liquor runs into a settling tank. The total cost is given at \$0.406 per ton of tailing, or \$0.05—0.06 per lb. of copper. The loss of ammonia is just under 1 lb. per ton of sand; the average extraction is now about 75%. There is no fouling of the liquors.—W. R. S.

[Copper ores:] Sulphatising [—] with weak sulphurous gases. G. C. Westby. *Eng. and Min. J.*, 1917, 104, 119—122.

THE low-grade ores from the Nevada Douglas Consolidated Copper Co.'s mine (Ludwig, Nev.), containing acid-soluble lime and alumina besides difficultly soluble copper minerals, are now successfully leached by direct contact with gases from the roasting furnaces in presence of steam and percolating liquor. The oxide or roasted sulphide ore is crushed to pass a 1-in. ring and discharged on to a 10 mesh-screen, oversize and undersize being treated separately. The coarse material is leached in six closed redwood towers, 40 ft. in diameter and 21 ft. high, provided with a filter bottom through which the hot gases are admitted; the gases are drawn off at the top of the ore column by hard-lead fans, and introduced into the next tower. The leaching liquors are sprayed on to the top of the ore by nozzles located around the inner periphery of the towers. The time required for leaching is as follows: 37% extraction, 10 days; 82%, 20 days; 92%, 30 days; 98%, 40 days. The slow action during the first 10 days is due to the sulphatisation of lime and alumina. The fine material is treated in four gas-tight tanks, 14 ft. in diameter and 20 ft. high, filled with a network of 1×1 in. wooden strips with 2×4 in. spacers, over which the fines and the liquor fall in retarded cascades through the sulphurous fumes. A steam jet blows the fumes through the tower and assists the action by raising the temperature. The cost of treatment is \$0.947 per ton of ore for coarse and \$0.930 for fine ore. The gases used contain from 0.3 to 5.5% of sulphur dioxide, but the process is equally successful with rich or poor gases. The dissolved copper is recovered by precipitation with iron.—W. R. S.

Copper refining: Impurities in electrolytic— L. Addicks. *Met. and Chem. Eng.*, 1917, 16, 687—692.

THE general question of impurities is discussed under five main headings: (1) sources, (2) exits, (3) distribution, (4) recovery of soluble impurities from the electrolyte, (5) recovery of insoluble impurities from the anode slimes. Apart from the pig copper, the chief sources of impurities are fuel, fluxes, and acids, and the exits are outgoing commercial products, slags, and stack gases; the tendency to-day is to check stack losses. The distribution of impurities depends partly upon their chemical characteristics and partly upon the metallurgical practice of the individual plant. Silver, gold, tellurium, and selenium, which do not dissolve in the electrolyte, show a cathode recovery of over 99%. Nickel passes into solution to the extent of nearly 99%, and arsenic forms a light slime, which passes chiefly into solution, the re-

covery being 97%. Iron and zinc also pass principally into the electrolyte, whilst lead, antimony, bismuth, and sulphur pass chiefly into the slimes. In the purification of the electrolyte, sufficient must be withdrawn daily to control the amounts of the chief impurities, generally nickel and arsenic. The early methods of purification consisted in separating the copper by means of scrap iron, but this was later displaced by the manufacture of commercial copper sulphate. The modern method of purifying the electrolyte is to divert part of it to tanks containing insoluble lead anodes, at a rate sufficient to keep the determining impurity, generally nickel or arsenic, at the desired point. From these tanks good cathode copper is obtained, then a poor copper which is returned to the anode furnaces, and finally sludge which passes to the smelter. The liquor is then passed into a steam boiling tank and into evaporators, and finally on to sand filters for removing the nickel salts, the liquor being afterwards cooled to separate the sodium salts. The strongly acid filtrate is then again used as electrolyte.—B. N.

Lead-zinc flotation; Selective —. L. L. Kirtley. Eng. and Min. J., 1917, 104, 64—66.

TESTS were made with quantities of 15—20 lb. of lead-zinc slimes such as are ordinarily treated on slime tables. The method of working aimed at obtaining the lead first in a concentrate as low in zinc as possible, with a tailing as low in lead as possible, and working up the latter for zinc. The highest lead extraction was obtained with 2 lb. of hardwood creosote per ton of dry slime, mixed with 5—7 times its weight of cold water containing 0.1% of sodium carbonate. For the recovery of zinc, a fuel oil called "Texana No. 7" proved a good filming agent, while Georgia pine turpentine No. 205 produced a serviceable froth. A mixture of the two oils was used (2 lb. per ton), the fuel oil always predominating. By adding $\frac{1}{2}$ lb. of copper sulphate per ton of slime, low-zinc tailings were obtained. The rough lead and zinc concentrates were again floated in "cleaners," the addition of oil being unnecessary. Some of the results obtained are tabulated below:

	Pb %	Zn %
average head assay	7.0	7.8
final lead product	35.8	12.4
final zinc product	16.2	29.3
extraction in lead product	58.3	18.1
extraction in zinc product	27.1	43.7

By making the zinc "cleaner" test shorter, the grade of the product could be raised to 33%. The machines used were of the Callow and Minerals separation type; the selective action seemed more pronounced in the Callow machine.

PATENTS.

Steel alloy. Stahlwerke R. Lindenberg A.-G., Remscheid-Hasten, Germany. Eng. Pat. 104,670, Aug. 17, 1916. Under Int. Conv., Feb. 26, 1916. (Appl. No. 11,664 of 1916.)

THE high speed steel contains, in addition to iron, 6—1.2% C, 1.0—2.0% Mn, 0.1—0.3% Si, 3.0—10.0% Cr, and 1.0—5.0% Co. It may be improved in efficiency by the addition of 0.15—2.0% of V.

—B. N.

Iron ore; Process for treating — for the recovery of iron and manufacture of steel therefrom. L. P. Burrows, Ottawa, Canada. Eng. Pat. 107,644, July 5, 1916. (Appl. No. 9475 of 1916.)

TEAM under pressure is allowed to expand within metal container surrounded by air, part of the

water is precipitated, whilst a portion of the oxygen in the steam is believed to "radiate" through the container. The gases passing from the container are heated, and then allowed to act upon the iron ore in a closed vessel, the product being finally withdrawn, and the metal recovered by melting.—B. N.

Crucible furnace for melting metals. P. V. Paisy, Paris. Eng. Pat. 102,959, Dec. 19, 1916. (Appl. No. 18,201 of 1916.) Under Int. Conv., Dec. 27, 1915.

THE crucible is placed in a small chamber communicating with a combustion chamber, below and to one side of it, having an inclined wall extending downward from the bottom of the crucible chamber. Gas burners are placed in the upper part of the lateral walls of the combustion chamber, and the burning gases pass over the crucible and thence into an exhaust chamber, through which or around which the secondary air for combustion is passed to preheat it. Any dross overflowing from the crucible runs down into the combustion chamber, from which it may be withdrawn through a door at the side.—W. F. F.

Crucible melting furnaces. I. Hall, Birmingham. Eng. Pat. 107,286, Aug. 10, 1916. (Appl. No. 11,279 of 1916.)

IN a crucible melting furnace using solid fuel such as coke, the crucible is supported on a stand carried by the firebars in a vertical cylindrical casing provided with a firebrick lining. An annular air passage is provided in the lining, below the firebars, into which air is injected tangentially and from which the air is delivered to the space below the firebars through radial openings in the lining. A door is provided in the outer casing extending above and below the firebars, so that the fire and the ash space below are both accessible. The door may carry a segment of the refractory lining containing the annular passage and radial openings.—W. F. F.

Crucible furnaces for use in melting metals. T. W. Aitken, Luton. Eng. Pat. 107,468, Aug. 21, 1916. (Appl. No. 11,828 of 1916.)

IN a crucible furnace for melting metals, an outer cylindrical casing supported on trunnions is provided with an inner refractory lining spaced from the casing so as to leave an annular space into which the air supply is delivered. Tuyères are provided in the refractory wall near the bottom, inclined downward and expanding laterally toward the combustion chamber, so that they practically meet one another at the inner wall and thus equalise the air blast. A similar set of tuyères is provided at a higher level to admit a further supply of air to deflect the hot gases toward the crucible. Each tuyère is provided with a corresponding inspection door in the outer casing.—W. F. F.

Furnaces. H. N. Davis and W. R. Twigg, Luton. Eng. Pats. (A) 107,263, (B) 107,264, and (C) 107,433, July 6, 1916. (Appl. Nos. 9543, 9545, and 9544 of 1916.)

(A) IN a gas or oil fired furnace for heating steel billets or ingots, crucibles, or the like, the combustible gaseous mixture is sprayed from a horizontal series of burners through a number of horizontal openings just below the crown of a half arch forming the roof of the combustion chamber. The objects to be heated are supported on a platform raised above the floor of the combustion chamber so that the hot gases deflected downward by the arch pass over and under the platform to vertical flues at the side extending downward to an outlet flue below the combustion chamber. The secondary air for combustion is preheated by passing it through a pipe in the outlet flue. (B) In a gas

or oil fired furnace for heating steel billets or ingots, crucibles, or the like, the combustion chamber is in the form of a frustum of a cone surrounding the article or articles to be heated, and the combustible mixture is fed into it through a tangential inlet at the lower end. The combustion chamber may be eccentric with relation to the billet or crucible being heated. (c) The furnace described in (b) is adapted for "glory holes" such as are used for reheating articles during manufacture. The frusto-conical combustion chamber is placed with its axis horizontal, and the object to be heated is inserted at the smaller end. The flame from the burner is injected tangentially at the larger end and the outlet opens tangentially from the smaller end.

—W. F. F.

Furnaces; Melting and reheating — W. Bache, Glasgow. Eng. Pat. 107,532, Dec. 27, 1916. (Appl. No. 18,475 of 1916.)

IN a reheating or melting furnace suitable for melting copper, brass, or aluminium, the fire-box, *d*, is provided with a water tank, *a*³, and a water-supply pipe above the fuel bed, so that combustion gases mixed with water-gas pass upward into the

horizontal flues, *c*, below the furnace bed, *c*. Hot air from a regenerator is added through the passage, *k*¹, and the mixture burns in a vertical passage leading to the furnace bed, *c*. The combustion products pass down through vertical passages, *l*, provided with partition plates to divert the gases in a zig-zag path through the openings, *f*¹, in the regenerator bricks, *f* (see fig. 2). Air for combustion is heated by passing in a zig-zag path through the passages formed by the grooves, *f*², at right angles to the openings, *f*¹. To complete the regenerator structure, hollow bricks, *g*, are used and at the ends in each series, *f*, the bricks are provided with perforated stoppers fitted with glass windows for inspection and cleaning.—W. F. F.

Sintering machines; Ignition furnaces for — H. Wade, London. From Metallurgical Co. of America, New York. Eng. Pat. 107,474, Aug. 30, 1916. (Appl. No. 12,310 of 1916.)

IN an ignition furnace for sintering machines, particularly of the continuous Dwight and Lloyd type, blast-furnace gas of poor quality may be used and

is supplied by the pipe, 6, and mixed with air from the pipe, 7, in the mixer, 5. Richer gas may also be supplied by the pipe, 8, and mixer, 9, if desired. The mixed gas passes into the space, 11, and thence through the perforated diaphragm, 14, to the burner nozzles, 15. The combustion chamber, 16,

is provided with a firebrick lining, 17, which practically fills it except for narrow vertical openings, 18, leading into a narrow inverted V-shaped combustion space, 19, so that a continuous line of flame is directed against the sintering charge, 4. The furnace is supported by adjustable rods, 20, so that the combustion chamber, 16, may be arranged close to the upper surface of the sintering charge, 4. The relative positions of the spaces, 11, 12, and the combustion chamber, 16, may be adjusted by bolts, 22. When oil or tar is used as a fuel it is atomised from a nozzle into the open top of the pipe, 10, the latter being lined with firebrick which is maintained at a red heat to gasify the oil or tar.

—W. F. F.

Tanks for rust proofing metals. W. C. Parker, Detroit, Mich., U.S.A. Eng. Pat. 103,288, Nov. 1, 1916. (Appl. No. 15,608 of 1916.) Under Int. Conv., Jan. 12, 1916.

A TANK particularly suitable for the treatment of metals by hot acids, is made double walled, the inner vessel communicating with the outer only by means of a row of holes near the top, or by the rim of the inner vessel being slightly below the liquid level in the outer vessel. When the liquid is heated by gas burners beneath the outer vessel, the liquid in the inner vessel is heated without disturbing the sediment. The bottom of the inner vessel is provided with a short pipe projecting upward and fitted with a valve, so that when the valve is opened and the vessel is slowly lifted out, the liquid flows through the pipe, leaving the sediment in the shallow layer at the bottom. The rim of the outer vessel is provided with an angle bar projecting inward to prevent the liquid from boiling over.—W. F. F.

Ores; Concentration of — E. Edser, H. L. Sulman, and Minerals Separation, Ltd., London. Eng. Pat. 107,401, May 25, 1916. (Appl. No. 7468 of 1916.)

IN the agitation-froth process for the concentration

of ores, such as described in Eng. Pats. 7803 of 1905, 2359 of 1909, and 21,857 of 1910 (this J., 1906, 184; 1910, 496, and 1911, 1263), when a flotation agent other than a soluble soap is employed, the ores are subjected either before or during the separation process to the action of silicic acid sol. The process is applicable to sulphide ores with a gangue containing clay, slate, mica, kaolin, calcite, and the like. A proportion of 1–10 lb. of silicic acid sol per ton of ore may be used, and the flotation agent may be eucalyptus oil, or a mineral substance such as blast-furnace creosote oil with or without pine tar. In some cases 1–3 lb. of sodium sulphate per ton of ore may also be added.—W. F. F.

Cleaning metal for painting: Process of — H. Wade, London. From American Chemical Paint Co., Philadelphia, Pa., U.S.A. Eng. Pat. 107,921, Dec. 7, 1916. (Appl. No. 17,616 of 1916.)

METALS such as iron or steel are cleaned for painting by applying to the surface a relatively strong solution of phosphoric acid and subsequently a relatively weak solution. For example, the first treatment may be made with a 14% solution of phosphoric acid in water or alcohol, and the second with a 4% solution or with water.—B. N.

Alloys; Metal — A. E. White, London. From American Alloys Co., Newark, N.J., U.S.A. Eng. Pat. 108,164, Apr. 26, 1916. (Appl. No. 5989 of 1916.)

Furnaces; Electric — D. F. Campbell, London, and Soc. Electro-Métallurgique Française, Froges, France. Eng. Pat. 107,465, Aug. 16, 1916. (Appl. No. 11,623 of 1916.)

THE hearth, together with the side walls and cover, of the furnace may be readily disconnected and removed from the back frame, which carries the electrodes, and to which it is rigidly secured under working conditions. The hearth may thus be replaced readily by a spare part when repairs are necessary.—B. N.

Electrical ozone generators. Ozonair, Ltd., and E. L. Joseph, London. Eng. Pat. 107,556, Mar. 20, 1917. (Appl. No. 4047 of 1917.)

THE electrodes are assembled so that the surfaces of those of the same polarity, in adjacent pairs of

electrodes, are close together, and a dielectric sheet is interposed between adjacent electrodes of opposite polarity. The electrodes are mounted upon a removable frame, formed from a removable cover, a bottom bar, and air inlet and outlet tubes connecting the cover with the bottom bar, and arranged in a closed container which is made watertight and immersed in a cooling tank. The air is led in parallel to the electrodes and passes between adjacent electrodes, and between electrodes and dielectrics. Several series of electrodes may be mounted within a single closed container, so that they are in substantially the same plane, and are thus adapted to act in succession upon the stream of air passed through.—B. N.

XII.—FATS; OILS; WAXES.

Orange-pip oil. D. G. Hewer, Analyst, 1917, 42, 271–273.

THE pips obtained from bitter oranges yield 37.5% of oil, or 55% calculated on the weight of the kernels alone. The oil is of a golden-yellow colour, odourless, and has a bitter flavour. Its analytical characteristics are as follows:—sp. gr. at 15° C., 0.9208; refractometer value at 40° C., 57.5; free fatty acids (as oleic), 0.3%; saponif. value, 193.7; iodine value, 100.3; titer test, 34° C.; unsaponifiable matter, 0.14%.—W. PATENTS.

Zinc compounds for use in paints or other purposes; Processes for the production of — A. Nihoul, Chatou, France. Eng. Pat. 107,265, July 7, 1916. (Appl. No. 9590 of 1916.) (See Eng. Pat. 14,226 of 1914; this J., 1915, 1009.)

INDUSTRIAL zinc residues are treated with hydrochloric acid, and when the attack is finished, the liquor is boiled with powdered zinc in order to precipitate lead, tin, and cadmium. The liquor is then treated with a current of chlorine, and zinc carbonate is added. To the filtrate from this liquor, consisting of a solution of zinc chloride, a proportionate quantity of magnesium carbonate is added and a current of carbon dioxide passed through; zinc carbonate is precipitated, and is filtered off and used as a pigment, or calcined to oxide. The residual liquor is evaporated to dryness and calcined at 150°–200° C. and up to 800° C. The magnesium oxide thus obtained is reconverted into carbonate, and the hydrochloric acid recovered in a coke tower, both being used again in the process.—E. W. L.

Synthetic resins; Method of manufacturing permanently fusible and soluble — from non-fusible phenolaldehyde resins. L. Berend, Amöneburg, Germany. Eng. Pat. 107,205, Mar. 15, 1916. (Appl. No. 3868 of 1916.)

THE non-fusible insoluble class of phenol-formaldehyde resins can be converted into soluble, fusible resins by heating them with fusible natural or artificial resins of various kinds, e.g., with colophony or coumarone resins, at 200°–300° C., in presence of such neutral salts or basic or acid contact substances as are used in effecting the phenol-formaldehyde condensation. For example, non-fusible resin, obtained by condensation of crude cresol with formaldehyde in the absence of a

contact medium, 106 parts, is heated with colophony, 150, and ammonium chloride, or hydrochloric acid, or caustic soda, 10 parts, for 3 hours in a closed vessel at 250° C. The resin compound obtained is completely soluble in a mixture of benzol and alcohol.—E. W. L.

Lithopone and process of manufacturing the same. R. B. Llopart, Cordoba, Argentine. Eng. Pat. 100,092, Feb. 19, 1916. (Appl. No. 2504 of 1916.) Under Int. Conv., Feb. 19, 1915.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber in the latex: State of colloidal aggregation of —. Van Heurn. Communication from Netherlands Govt. Inst. for Advising Rubber Trade and Industry. India Rubber J., 1917, 54, 150.

THE author finds that the viscosity number—which gives a measure of viscosity independent of concentration—of the material forming the uncoagulated globules of rubber latex, as extracted from the latter by benzene, is certainly not lower than that of rubber obtained from the latex by coagulation. The extraction was effected with different proportions of benzene, viz., 10, 20, and 200 c.c. respectively to 10 c.c. of latex which had been preserved with ammonia and subsequently dialysed for six days, when it contained about 22% of caoutchouc. The two liquids were shaken vigorously together in a stoppered bottle. With the smaller quantities of benzene a homogeneous, more or less solid ball of emulsion was formed. This was transferred completely to a brown bottle and broken up in contact with 190 c.c. of benzene. The ball passed into solution in the course of about 2 days' shaking. The milky solution was left in a beaker in a desiccator for 13 days in a dark cupboard. The viscosity numbers of the clear solutions thus obtained were 81.5 and 68.8 respectively. When the larger quantity of benzene (200 c.c.) was used no ball of emulsion was obtained, and the viscosity number of the clear solution which separated was 60.1. The viscosity numbers of samples of rubber obtained from the same latex by coagulation with acetic acid (at a slightly elevated temperature) were 29, 62, and 64.7 respectively; these figures are, however, too low on account of incomplete solution of the rubber.—E. W. L.

[Rubber] latex: Non-caoutchouc compounds of —. P. Dekker. India Rubber J., 1917, 54, 154—155.

DIALYSIS of latex containing 29% of caoutchouc and 32.4% total solids, which had been preserved with ammonia, resulted in the removal of 3.2% of solid matter (calculated on the latex). The dark brown, hygroscopic solids of the dialysate were no longer completely soluble in water. They contained protein equivalent to 0.45% on the original latex, calculated from Kjeldahl nitrogen using the factor 6.25, but of this 0.06% was found to be present as ammoniacal nitrogen. Acetone and ether extracts of the dialysate evaporated to dryness with powdered pumice amounted to 0.66 and 0.25% respectively on the original latex.

After evaporation of the dialysate with half its volume of 25% hydrochloric acid, together with powdered pumice, the acetone extract in 6 hours amounted to 1.59% on the original latex. The extracts were not completely soluble in water. It is improbable that the increase of extract on treatment with acid is due to decomposition of the resins previously saponified by the ammonia, since only a few milligrams of residue was obtained on acidifying the dialysate and agitating with ether.—E. W. L.

Hevea brasiliensis: Bacteriological study of the natural coagulation of latex of —. Denier and Vernet. Comptes rend., 1917, 165, 123—126.

SAMPLES of latex were collected, with precautions against extraneous infection, from five trees near Saigon (Indo-China), and investigations were made of the bacterial flora at different stages in the course of spontaneous coagulation, which process occupied about 48 hours. Twenty-six species of various types were isolated, 25 of which were aerobes or facultative aerobes. The samples differed greatly in respect of the species present, but one organism was found in all. It is a short bacillus with rounded ends, only slightly motile, and not stained by Gram's method. Cultures on agar show a greyish white surface, not very characteristic. On agar containing latex serum, tinted with litmus, it develops rapidly, causing reddening and then decolorisation and shrinking (*dislocation*). Litmus agar containing sucrose or lactose becomes red and shrinks, and milk is also acidified and coagulated. The organism exerts no proteolytic action on coagulated egg-albumin, but liquefies gelatin. It gives rise to evolution of gas. By introducing this organism into latex, complete coagulation can be attained in 24 hours, and this practice has been adopted for several months past at Nha-Trang. To obtain the best results certain precautions are necessary. When coagulation is slow it may be accelerated by adding sugar (cp. Eaton and Grantham, this J., 1916, 263); 1 gm. of sugar per litre of latex is usually more than sufficient. The development of aerobic bacteria which produce an alkaline scum (cp. *loc. cit.*) may be checked by covering the surface of the latex with a simple wooden float. The rubbers produced in this way are white at first, but to prevent discoloration it is necessary to sterilise them by heat or by means of formalin, or the same result may be attained by protecting them from contact with the air for at least 4 days. Coagulation should not be conducted in zinc receptacles, as this metal appears to exert a toxic action on the bacteria of latex.—J. H. L.

Rubber: The different methods of preparing —. Dekker. Communication from the Netherlands Government Institute for Advising the Rubber Trade and Industry. India Rubber J., 1917, 54, 194.

A RECORD of observations on the influence of the method of coagulation on the properties of the final rubber. Rubber was separated from preserved latex taken from trees planted in 1898, by (1) evaporation, with subsequent washing of the product; (2) coagulation with acetic acid, followed by washing; (3) evaporation, followed by drying in a vacuum without washing; (4) evaporation, after dialysis of the latex for 4 days; (5) coagulation with acetic acid after the latex had been dialysed for 4 days; (6) evaporation after 14 days' dialysis; (7) coagulation with acetic acid after 14 days' dialysis. The product in each of the last four experiments being finally washed and air-dried. The various samples obtained were examined as to their content of moisture, ash, proteins, total matter insoluble in petroleum, and resinous matter; the portion of the acetone extract which was soluble in water was also determined and the viscosity of the benzene solution

of each product was measured. It was found that dialysis reduces slightly the proportion of resinous matter and also, as was to be expected, the proportion of mineral matter and water-soluble organic matter. The rubber obtained by evaporation had a higher protein content than the samples prepared by coagulation and was also exceptionally hygroscopic. The viscosity of rubber prepared by evaporation was somewhat lower than that obtained by coagulation, whilst with the sample obtained by evaporation of the dialysed latex the reduction in viscosity was still more marked. Reference is also made to other investigations of the above Institute, and it is stated that samples of rubber produced by an electrical method, although of normal composition, have been found to possess remarkable viscosity, speed of vulcanisation, and mechanical properties after vulcanisation.

—D. F. T.

Vulcanisation results obtained with rubbers from seven plantations. P. Schidrowitz and H. A. Goldsbrough. *Indiarubber J.* 1917. 54, 162—167 and 184—187.

A RECORD of the results of vulcanisation tests made by the authors' methods (this *J.* 1916. 550) with approximately 500 samples of rubber derived from seven plantations, four in Sumatra and the remaining three in the Federated Malay States. The results are tabulated and also summarised to show the relative average values for the various qualities and plantations. As an outcome of the work it is possible to draw the conclusion that smoked sheet vulcanises more rapidly than first latex crêpes, although the amount of the difference is variable. There is a marked variation as regards rate of vulcanisation between the products of the various plantations, more especially amongst the smoked sheet and first latex grades. The rate of vulcanisation of the smoked sheet samples was more nearly constant than that of the samples of first latex crêpe, 119 out of 148 of the former having a period of vulcanisation between 2 and 2½ hours, whereas only 88 out of 132 of the latter quality required a period of 2½ to 3½ hours. The results for the brown crêpes showed less wide variation in rate of vulcanisation than the better grades, although in "type" and mechanical properties they were much more irregular. In "type" the first latex crêpes showed a slightly but distinctly better average than the samples of smoked sheets, but in average tensile properties a slight advantage lay with the latter. The samples of brown crêpe were inferior to the two better qualities in "type" and were decidedly inconstant in tensile characteristics.—D. F. T.

Chicle and chewing gum ; The industrial chemistry of —. F. Dannerth. *J. Ind. Eng. Chem.* 1917, 9, 679—682.

THE estimated imports of chicle into the United States for 1916 amounted to 7,347,000 lb., equivalent to at least 30,000,000 lb. of chewing gum. As it arrives it usually contains about 40% of moisture ; other factors affecting its value are the shrinkage when cleaned, the chewing quality of the purified product, and the colour. The raw material costs about 55 cents (2s. 3½d.) per lb. A sample from Yucatan showed on analysis :—Acetone-soluble matter (resins), 40.0 ; gutta and carbohydrates, 17.4 ; proteins, 0.6 ; sand and foreign matter, 2.3 ; water, 35.0 ; mineral matter (ash), 4.7%. In sampling, about 1 lb. is cut from a block of the crude gum and immediately cut up into ½ in. crumbs which are rapidly sealed up in an air-tight jar. The moisture may be determined by drying for 5 hours in a well-ventilated air-bath at a temperature not exceeding 50° C. Alternatively it may be determined by difference in the determination of the acetone extract. For the determination of the viscosity 20 grms. of chicle,

dried for 12 hours at 70° C. *in vacuo*, is placed in a basket of 100-mesh wire which is suspended in 75 c.c. of "kerosene" ; when the liquid has completely strained through, leaving the foreign matter in the basket, it is diluted with kerosene to 100 c.c., cooled to 20° C., and placed in the small tank of a Stormer viscosimeter ; the lower portion of the capsule of the viscosimeter is filled with shot until it weighs exactly 20 grms. and the viscosity is determined in terms of revs. per min. of the rotating cylinder. The acetone-extract or "resin" is determined on 5 grms. of the sample granulated to pass a ½ in. screen and extracted in a folded filter paper in a Soxhlet apparatus for 5 hours. The extract is dried at 105° C. and the residue at 85° C. as it readily carbonises at higher temperatures ; the difference between the sum of the weights of extract and residue and the weight of the original sample indicates the moisture. As a rule the viscosity is proportional to the resin content. A number of problems for industrial research in connection with chicle are stated. Moist chicle readily undergoes fermentation by mould fungi with a considerable modification of its chewing properties.—J. F. B.

XVI.—SOILS ; FERTILISERS.

Soil flora studies. I. General characteristics of the microscopic flora of soil. II. Methods best adapted to the study of soil flora. III. Spore-forming bacteria in soil. IV. Non-spore-forming bacteria in soil. H. J. Conn. *Tech. Bull.* Nos. 57, 58, and 59. New York Agric. Exper. Stat., Dept. Agric., U.S.A. Jan. and March, 1917. pp. 1—42 ; 1—16 ; 1—18.

I. THE microscopic flora of various soils from New York State have been studied, the number of bacteria being determined by the plate method. For quantitative purposes the results thus obtained are regarded as inaccurate, and the chief use of the method is to estimate the relative proportions of the different organisms, and to distinguish them by the appearance of the colonies on the plate. Of all the soil micro-organisms the most abundant were non-spore-forming bacteria (mainly non-motile rods). Of these 40 to 75% liquefied gelatin either very slowly or not at all, whilst under 10% were short rods with polar flagella (principally *Ps. fluorescens*, which rapidly liquefied gelatin. From 12 to 75% of various types of actinomycetes were the next most important organisms, the remainder consisting of 5 to 10% of spore-forming bacteria (*B. subtilis* group), and a few micrococci. The bacteria isolated were quite different from those occurring in milk, cheese, or water. They showed a striking uniformity both in their character and in their quantity. In the case of every soil studied the predominating types were the same, whilst the number of colonies developing on gelatin or agar plates incubated for 7 days at 18° C. was usually between 5 and 50 million per grm. of soil. II. The best results are obtained by incubating the plates at fairly low temperatures (18° C. for gelatin and not over 25° C. for agar) for at least 7 days. For relative quantitative results the exact composition of the culture medium is not of material importance, but for qualitative work plates of definite composition are necessary. Thus spore-forming bacteria may frequently be recognised by the appearance of their colonies on 15 to 18% Gold Label gelatin (in tap water) ; whilst some, but not all, actinomycetes form characteristic colonies on asparaginate-glycerin agar. No suitable medium for the recognition of the different non-spore-formers has been found, although *Ps. fluorescens* may be readily identified. For a complete examination of soil flora it is advis-

able to make cultivations on plates of at least three media, and to make sub-cultures of the types not recognisable by the appearance of their colonies. III. The three most abundant spore-forming bacteria in the soils examined were:—*B. megathicum* (De Bary), *B. mycoides* (Flügge), and *B. cercus* (Frankland), whilst *B. simplex* (Gottheil) was present in smaller proportion. Occasionally other spore-forming bacteria were found, but not in sufficient quantity to be regarded as important. Hitherto, spore-forming bacteria have been considered as active agents in the soil, but the results now obtained indicate that they occur in normal soil only in the form of spores, and are apparently usually inactive. IV. The only non-spore-forming bacterium identified with species previously described was *Ps. fluorescens* (Flügge), which is abundant in freshly aerated soil or in soil to which organic matter has recently been added. In pure cultures it produces ammonia, and may therefore play a part in the decomposition of organic matter. Several other liquefying non-spore-forming organisms closely related to *Ps. fluorescens* were also isolated. Apparently these have similar functions. The numbers of non-spore-forming bacteria in soil show greater fluctuations than do those of the other soil bacteria. They are among the most active micro-organisms in the soil.—C. A. M.

Humus content of the soil as a criterion of fertility.
R. H. Carr. Soil Sci., 1917, 3, 515—524.

A CLAY surface soil deficient in organic matter was screened, mixed with various farm and green manures, and placed in double boxes, holding about 1 cu. ft., which were buried in a trench so that the tops projected a little above the level of the surrounding ground. In each box the proportion of manure mixed with chalk, lime, or lime-magnesia was equivalent to 1 lb. of dry substance. The ammonia-soluble material was determined at the time when the manures were added, and at various subsequent periods. The yields of maize in boxes fertilised with green manures were also determined. The results indicated that the growth of plants is greatly stimulated by the rapid humification of manure, this being particularly noticeable in cases where green manures were rolled under the surface and limed, rather than uniformly mixed with the soil. Certain manures, notably steer manure and alfalfa (lucerne) and to a less extent cow manure, appear to be as soluble in 4% ammonia solution immediately after admixture with the soil as after humification. In the case of horse manure, however, humification appears to take place very slowly, and it is largely unavailable as plant food during the first year. By the addition of dolomitic limestone the rate of humification of horse manure during the first year may be increased, and the boxes thus treated gave better crops. In the case of the other manures the organic matter left in the soil did not have any pronounced effect in stimulating the growth of maize during the second year. No relationship could be traced between the amount of ash in the humus and the growth of the plants, but the humification and vegetation tests indicated a close relationship between the amount of humus and the growth.—C. A. M.

Soil acidity: Effect of ammonium sulphate on —.
F. E. Allison and R. C. Cook. Soil Sci., 1917, 3, 507—512.

SERIES of five small pots with a capacity of about 2½ lb. each were filled with five types of soil and with nearly pure quartz sand. In each series four of the pots were treated with 1 gm. each of acid phosphate (superphosphate) and potassium sulphate, and half of these were treated with 0.5 gm. of ammonium sulphate. One each of the

treated and untreated pots was planted with buckwheat, whilst the others were left fallow. After each three months an additional 0.5 gm. of ammonium sulphate was added, until a total of 2 grms. was reached, and four crops had been grown. The total yields of the crops and the nitrogen left in the various soils were then determined and, after the last crop, the soils were air-dried and their lime requirement determined by the Veitch method. It was found that in the case of the soils which had received no ammonium sulphate the increases in the acidity during a year were practically the same whether crops had been grown in them or not. The quartz sand showed the smallest increase in acidity, and a loam soil the largest, but no relationship was established between the texture of the soil and the accumulation of acid. A pronounced increase in the acidity of the soil was found in the pots which had been treated with ammonium sulphate. Speaking generally, the removal of a portion of the nitrogen by the buckwheat had no pronounced effect upon the acidity, the quartz sand and heavy clay soil showing a decrease, whilst the loam showed an increase, the other three soils remaining practically the same. Excluding the quartz sand, the average increase in the acidity of the soils was equivalent to 4140 lb. of calcium oxide per 3,000,000 lb. of soil when left fallow, and to 4240 lb. where four crops had been grown. The average increase in the acidity of the soil under the experimental conditions was equivalent to about 80 lb. of calcium oxide for each 100 lb. of ammonium sulphate applied.—C. A. M.

Soil solution: Oil pressure method of obtaining —.
J. F. Morgan. Soil Sci., 1917, 3, 531—545.

IN the method of van Suchtelen and Itano (J. Landw., 60, 369) the soil is closely packed in a cast-iron cylinder, provided with a wire gauze bottom on a perforated plate, and having a small spout through which the soil solution is driven by means of paraffin oil forced through the soil by a pump. The amount of moisture thus removed depends upon the nature of the soil and the amount of organic matter present. In the case of fine sandy soils with little organic matter, over 70% of the total moisture may be extracted, but heavy clay loams may yield as little as about 2% of the moisture. Successive portions of the same extraction vary but slightly in physical properties, but show considerable differences in the proportions of the different forms of nitrogen. Calcium and magnesium also vary according to the treatment and reaction of the soil. The amount of phosphoric acid is fairly constant, but the potassium varies to some extent. Only a small proportion of the bacteria in the soil is found in the extract, since the soil acts as a filter. If the cylinder is allowed to stand too long an aerobic decomposition occurs, particularly in the case of clay soils and soils rich in organic matter. The results tabulated indicate that the method usually gives a fairly representative soil solution, but in some cases the oil does not completely penetrate the soil, and thus expels less moisture than might be otherwise obtained.—C. A. M.

Soils: Effect of sterilisation of — by heat and antiseptics upon the concentration of the soil solution.
G. P. Koch. Soil Sci., 1917, 3, 525—530.

SEVERAL soils were sterilised by methods similar to the "commercial" processes of steaming, treatment with formalin, and both, and two weeks later they were air-dried, and 20-grm. portions were mixed with water, and left for 12 to 16 hours in stoppered jars. The concentration of the soil solution was then determined by the depression of the freezing point as suggested by Bouyoucos (Mich. Agric.

Exper. Sta. Tech. Bull., 1915, No. 24), which was proved to give trustworthy results. It was found that in practically every instance sterilisation by the "commercial" methods increased the concentration of the soil solution. The heavier soils were more affected than the lighter soils by the treatment. Steaming alone was more effective in increasing the concentration than treatment with formalin (1:50 or 1:100), but the greatest increase was obtained by the use of formalin (1:50) followed by steaming at a pressure of 10 lb. If the amount of antiseptic used is in excess of what the soil can retain, a considerable amount of soluble matter will be removed and the concentration will be lowered. In the case of a sample of Norfolk sand containing a very small amount of organic matter, steaming effected no perceptible alteration in the concentration of the solution, but by adding 1% of dried blood to the sand an increase of concentration equivalent to 0.09 atmos. osmotic pressure was produced, whilst by the addition of 2% of cottonseed meal the increase was equivalent to 0.241 atmos. osmotic pressure. —C. A. M.

Hydrogen and hydroxyl ions; Effect of concentration of — on the growth of barley seedlings.
D. R. Hoagland. Soil Sci., 1917, 3, 547—559.

BARLEY seedlings were grown in solutions containing potassium phosphates and sodium nitrate, sulphate, and chloride. The OH-ion concentration was varied by using different proportions of potassium phosphate and dipotassium hydrogen phosphate, and the H-ion concentration of all solutions was determined electrometrically. It was found that the OH-ion in such solutions was more toxic than the H-ion. Under the experimental conditions a concentration of OH-ion greater than 1.8×10^{-6} was decidedly injurious, and one exceeding 2.5×10^{-5} was very toxic. Growth was promoted by a concentration of H-ions of about 0.7×10^{-5} , but a concentration of 0.3×10^{-3} was very toxic. Seedlings grown in solutions containing pieces of aluminium foil showed signs of injury to the roots. —C. A. M.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose and invert-sugar; Action of acids on the rotatory power of — in presence of soluble salts.
E. Saillard. Comptes rend., 1917, 165, 116—118.

SOLUBLE salts, such as chlorides and acetates, augment the dextro-rotation of sucrose, and to a relatively greater extent the lævo-rotation of invert-sugar. The author made some experiments to ascertain the joint effect of sodium chloride and certain acids. The influence of the salt on the rotation of sucrose is not affected by the presence of sulphurous, acetic, or carbonic acid. Sulphurous and acetic acids reduce slightly the rotation of invert-sugar in presence of sodium chloride, i.e., they tend to annul the effect of the latter. Hydrochloric acid, on the other hand, increases the rotation of invert-sugar whether alone or in presence of salt; e.g., the author obtained a reading of -13.13° with a solution containing 4 grms. of salt per 100 c.c., and one of -14.15° with a solution containing the same quantities of sugar and salt besides 10 c.c. of hydrochloric acid per 100 c.c. —J. H. L.

Caramel; The chemistry of —. I. Caramelan.
M. Cunningham and C. Dorée. Chem. Soc. Trans., 1917, 111, 589—608.

WHEN sucrose is heated at 170° — 180° C., the loss of weight of 12% which takes place does not consist merely of water; even at 168° C. other products, including furfural, pungent vapours, and

carbon dioxide, are evolved. Nevertheless, by heating sucrose at 170° — 180° C. until the loss of weight is 12%, practically pure caramelan, free from sucrose and higher caramel products, is obtained; the treatment of 300 grms. of sugar requires about 4 hours. When perfectly dry, caramelan melts at 136° C., but if at all moist it begins to soften at 100° C. It is fairly soluble in 84% alcohol, pyridine, methyl alcohol, or hot glacial acetic acid. It reduces silver nitrate and Fehling's solution and gives red precipitates with hydrochloric acid and resorcinol or phloroglucinol. It may be precipitated from aqueous solution in a flocculent state by alcohol if acetic acid be present. Its composition corresponds to the formula $C_{12}H_{18}O_9$ or $C_{24}H_{36}O_{18}$, its reactions rather indicating the latter. It behaves as a tetrahydric alcohol, yielding a tetra-acetate (m.p. 107° C.), a tetrabenzoate (m.p. 105° C.) and an explosive tetranitrate. Caramelan forms compounds with phenylhydrazine and semicarbazide which appear to indicate the presence of one carbonyl group in each C_{24} unit, but in all cases these are formed with extensive dehydration, which, being variable according to the conditions, makes the evidence somewhat inconclusive. Concentrated non-oxidising acids, e.g., 40% hydrochloric acid, convert caramelan into caramelin, $C_{24}H_{36}O_{15}$; and therefore have a dehydrating action; caramelin is infusible and insoluble in alkali hydroxides. Dilute acids hydrolyse and dehydrate it, producing dextrose, methylfurfural, and humic acid. The humic acid forms chloro and nitro compounds. Dilute nitric acid has an oxidising, dehydrating, and nitrating action. On oxidation, caramelan tends to yield complex substances and in nearly all cases one carbon atom is removed per C_{24} unit. Among simpler products acetaldehyde has been recognised. Caramelan appears to mark the first step in anhydride formation and condensation which leads from simple sugars to such complex substances as cellulose, humus, and caramelin. —J. F. B.

PATENT.

Cellulose; Process for converting — into glucose.
R. A. Kocher, San Francisco, U.S.A. Eng. Pat. 107,219, May 23, 1916. (Appl. No. 7339 of 1916.)

CELLULOSIC material, e.g., sawdust, is treated with aqueous hydrochloric acid at a concentration of 40% or more, the quantity of liquid present being only sufficient to moisten the charge. For example the material, moistened with not less than 10% of water, may be contained in a closed vessel into which sufficient gaseous hydrochloric acid is introduced to saturate the moisture present. At the ordinary temperature almost quantitative saccharification is effected in 24—48 hours. The action may be greatly accelerated by operating at 40° — 60° C. but the gas must then be kept under pressure to maintain a concentration of 40% of acid in the moisture present in the charge. After hydrolysis the acid may be recovered. —J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Barley; Proteins of —, in the grain itself and during the brewing processes. IV. Investigations as to malting power of various sorts of barley.
H. Schjerning and J. Hempel. Comptes rend. Trav. Lab. Carlsberg, 1917, 11, 333—378. (See also this J., 1906, 1109; 1910, 583; 1913, 985; 1915, 43.)

THE object of the present investigation, which was commenced only two years before Schjerning's death, was to ascertain whether the malting quality of a barley is a typical hereditary quality, and if so, how far it may be affected by the nature

of the soil. Various races of barley, from the Stations at Svålof, Tystofte, and Abed, were studied, some for two and some for three years (1912-1914). The analytical data are given in numerous tables. They furnish no answer to the question at issue, the period over which the experiments extended being far too short for the solution of such a problem. No typical racial peculiarity was observed in respect of any of the factors chiefly studied, viz., protein transformation (though one race, Golden Barley, appeared characterised by a deficiency of proteolytic enzymes), carbohydrate conversion (formation of extract), production of acidity, and loss by oxidation and rootlet growth. There was evidence that size of corn is a racial character.—J. H. L.

Malt amylase: Influence of certain electrolytes upon the course of hydrolysis of starch by —. H. C. Sherman and J. A. Walker. J. Amer. Chem. Soc., 1917, 39, 1176-1193. (See also this J., 1915, 371.)

THE hydrolysis of soluble starch by highly purified malt amylase (see this J., 1913, 986; 1915, 371) was studied in neutral solutions and in presence of hydrochloric acid, phosphoric acid, and monopotassium phosphate. Amylase of diastatic power 1060 on the authors' scale (see this J., 1910, 1173), corresponding to about 1600 Lintner, was employed at concentrations ranging from 0.0000125 to 0.00120%, higher concentrations being too active for quantitative purposes. The conversions were carried out at 40°C., with Lintner's soluble starch, further purified, as substrate, usually at concentrations of 1 or 2%, and reducing powers were calculated in terms of maltose. The electrolytes named, added in quantities sufficient to produce approximately the optimum concentration of hydrogen ions, increased the activity of the enzyme throughout the whole course of hydrolysis. Their activating influence was less the greater the concentration of enzyme, and was imperceptible with the highest enzyme concentrations, which moreover produced yields of maltose much greater than that (80% of the theoretical) held by some investigators to be the highest attainable with malt amylase. The same optimum hydron concentration, $C_H = 10^{-4.4}$, was found to hold for each of the electrolytes, and throughout the course of hydrolysis. With the purified Lintner's starch used, twice as much electrolyte was required to produce this optimum reaction in 2% as in 1% starch solutions, probably owing to fixation of hydrogen ions by the starch itself or by the alkali previously added to render it neutral. When more than the optimum amount of hydrochloric acid was added, hydrolysis proceeded at less than the optimum rate throughout; when less was added, the initial rate was better sustained, the activating effect becoming relatively more marked as the concentration of starch diminished in the course of hydrolysis. Similar relations were observed with the other electrolytes, but the differences were less pronounced owing to "buffer" action; with acid phosphate in particular, variations in concentration from $\frac{1}{10}$ to 5 times the optimum did not affect the rate of hydrolysis very greatly. In experiments with small concentrations of enzyme and favourable amounts of electrolytes, the rate of maltose production was found to be proportional to the concentration of starch, i.e., the reaction proceeded as unimolecular, until about 50% of the theoretical yield of maltose had been formed. No "region of linear relation" was observed, though during the early stages of slow conversions the yield of reducing sugar was almost proportional to the time, as required by the law of unimolecular reactions. Within the limits of enzyme concentration suitable for quantitative purposes, the time required to form a

given amount of maltose, up to 50% of the theoretical yield, was found to be inversely proportional to the enzyme concentration, *ceteris paribus*; this observation broadens the range within which diastatic activities may be compared quantitatively.—J. H. L.

Malt amylase: Effect of bromides on the action of —. A. W. Thomas. J. Amer. Chem. Soc., 1917, 39, 1501-1503.

IN experiments on the activating influence of salts on highly purified malt amylase, sodium and potassium bromides differed from the chlorides, nitrates, sulphates, and phosphates, in exerting an inhibitory influence at concentrations below about 0.2 M. At higher concentrations the bromides produced activation, like the other salts.—J. H. L.

Reducing enzymes: Investigations on —. A. Bach. Monit. Scient., 1917, 61, 149-153. (See also this J., 1911, 917.)

EXPERIMENTS described indicate that the formation of nitrite from nitrate by the reductase of milk and potatoes takes place in presence of aldehydes generally, irrespective of their chemical constitution (see this J., 1917, 469). The quantity of nitrite formed is in all cases small, and does not exceed 0.6% of the nitrate present, even under optimal conditions, i.e., in liquids containing about 5% of nitrate and 1% of acetaldehyde. The smallness of the yield of nitrite is not yet explained. It does not appear to be due to a toxic action of aldehydes on the reductase, and experiments indicate that hydroxylamine, which may possibly be produced in small amounts by further reduction of the nitrite, is not sufficiently toxic towards the enzyme to account for the feeble activity of the latter.—J. H. L.

Enzyme reactions: Law of mass action and —. O. Bailly. Comptes rend., 1917, 167, 248-250.

FROM data published by Bourquelot and Verdon (see this J., 1913, 456) relating to the equilibria produced in aqueous methyl alcoholic solutions of dextrose under the influence of emulsin (β -glucosidase), the author calculates that the reactions involved conform to the law of mass action.—J. H. L.

Enzyme action: Studies on —. XIV. Further experiments on lipolytic actions. K. G. Falk. J. Biol. Chem., 1917, 31, 97-123.

THE experiments were carried out on two preparations from castor beans: an albumin-like substance, more active towards ethyl butyrate, called the "esterase" preparation, and a globulin-like substance, more active towards glyceryl triacetate, designated the "lipase" preparation. The conditions of the inactivation of these preparations by various agencies, such as acids, alkalis, neutral salts, alcohols, acetone, esters, and heat have been studied, and the results indicate that such inactivation is due to a tautomeric change. The hypothesis is put forward that the active enzyme grouping in these substances of protein nature possesses the enol-lactim structure C(OH):N which becomes inactive by tautomeric change into the keto-lactam structure CO-NH . This hypothesis has been tested by studying the action of simple compounds capable of existing in tautomeric modifications of the configuration indicated, viz., dipeptides, amino-acids, and an imino-ester (ethyl iminobenzoate). Conditions were established under which these substances exerted a hydrolysing action similar to that of the natural lipases, particularly in the presence of alkalis, which is held to favour the existence of the enol-lactim form. Agencies, such as heat, acids, and alkalis, outside certain limits of hydrogen-ion concentration, were found to destroy

the activity of these simple substances in a manner similar to the inactivation of lipases. Substances capable of hydrolysing esters were also produced by the action of alkalis on proteins (gelatin, casein, etc.) under conditions which might be expected to form the hypothetical active grouping mentioned. In these experiments it would appear that the association of the protein colloid with the active grouping plays a part in the results obtained.

—J. F. B.

Enzyme action; Studies on —. XV. Factors influencing the proteolytic action of papain. E. M. Frankel. J. Biol. Chem., 1917, 31, 201—215.

A COMMERCIAL sample of crude papain was concentrated and purified by macerating with water over-night, decanting off the clear solution, and precipitating with 2—3 vols. of acetone. The precipitate was collected, washed with acetone, and ground up with warm water; the turbid solution was allowed to stand for 36 hours and the clear liquid poured into 5 vols. of 95% alcohol. The conditions of acidity for the optimum activity of the purified papain were determined and found to correspond to a hydrogen-ion concentration of 10^{-5} . A consideration of the quantitative relations between papain and its substratum indicated that this enzyme acts like urease, invertase, and lipase, forming an intermediate compound which is broken up into the cleavage products and liberates the enzyme. The experiments also support the view that there is a definite quantity of enzyme required for a given amount of substratum and that an excess causes little more action. The influence of hydrocyanic acid in papain hydrolysis is specific. There is some difficulty in defining a hydrogen-ion optimum in the case of hydrocyanic acid; the enzyme is equally active, or nearly so, over a wide range of acidity. The quantitative relations of the enzyme, hydrocyanic acid, and protein lend support to the view that there is a ternary intermediate compound formed by the components, which then breaks down into cleavage products of the protein, liberating the enzyme and hydrocyanic acid. The hydrocyanic acid is not used up in the reaction and may be recovered almost quantitatively from the digestion mixtures. Papain, with or without hydrocyanic acid, appears to have no proteolytic effect on certain dipeptides studied. Hydrocyanic acid can renew proteolytic action in digestion mixtures which are almost in equilibrium.—J. F. B.

Citric acid fermentation of Aspergillus niger. J. N. Currie. J. Biol. Chem., 1917, 31, 15—37.

IN the citric acid fermentation of sucrose by *Aspergillus niger* the mycelium floats on the surface of the substratum and wrinkles up in such a manner as to present a very large surface of contact. These wrinkled structures often project 5—6 cm. into the medium and exhaustion of the substratum proceeds under very favourable circumstances. By a judicious selection of cultures and conditions the yield of citric acid can be varied from nil to over 50% of the sugar consumed. Conditions especially favourable to citric acid formation are low nitrogen supply, high concentration of sugar, and the use of ammonium salts instead of nitrates. As regards the reaction of the medium, the hydrogen-ion concentration is a far more important factor than the titratable acidity. For a given hydrogen-ion concentration (p^H) a mineral acid, such as hydrochloric, is less toxic than an organic acid. The addition of calcium carbonate is disadvantageous rather than helpful; the cultures readily produce a solution of 10% citric acid and the limiting hydrogen-ion concentration is exceptionally high. Fermentation can be started at a hydrogen-ion concentration which will greatly reduce the chance of infection

without interfering with the growth. Higher yields in a shorter time are obtained without calcium carbonate than with it, as the carbonate partially precipitates the magnesium and phosphate nutrients; moreover the formation of calcium citrate is a hindrance in recovering the citric acid. It is possible to ferment two or three batches of medium in succession with the same mycelial felt by draining off the liquid and running in a fresh batch. The most suitable medium for conducting the citric acid fermentation has the following approximate composition per litre:—Sucrose, 125—150 grms.; ammonium nitrate, 2.0—2.5; potassium dihydrogen phosphate, 0.75—1.0; crystallised magnesium sulphate, 0.20—0.25 gm.; hydrochloric acid to $p^H=3.4$ —3.5 (5—4 c.c. of N/5 acid). The use of this quantity of hydrochloric acid makes it possible to sterilise the liquid completely by steaming at atmospheric pressure for 30 mins. and prevents subsequent infection without interfering with the fermentation. In a medium of this nature there is little development of acid in the first 2 or 3 days; when a vigorous mycelium has developed the rise in acidity is very rapid—about 2% in 24 hours—until the 7th or 8th day. After remaining constant for 2 or 3 days the acidity begins to decline. In a proper fermentation the fungus does not produce spores but remains white. Under favourable conditions the acidity will reach 10—12% on the 8th day; oxalic acid may amount to 3—4% of the total acidity. Fermentation may be carried out successfully in shallow pans and the liquid pressed out from the mycelium in a filter-press.

—J. F. B.

Fermentation organisms; Preservation of — in nutrient media. A. Klöcker. Comptes rend. Trav. Lab. Carlsberg, 1917, 11, 297—311. (See also Hansen, this J., 1898, 1064.)

DATA are given respecting the longevity of a great variety of yeasts and moulds in 10% sucrose solution, beer wort of 13—14° Balling, and other media. Over 800 cultures, ranging in age from about 2 to 30 years, were examined, and the numbers of cultures of each organism found to be dead and living respectively after these various periods of storage, are shown in a series of tables. In general both sucrose solution and beer wort proved excellent media for preserving the organisms, many of which were capable of surviving storage in either for 30 years, though not all their cultures lasted so long. Sucrose solution is, however, considered preferable to beer wort except in special cases, as variations in the composition of worts occasionally give rise to very unsatisfactory results. Among the organisms of lower longevity were *Saccharomyces Ludwigii* and some *Schizosaccharomyces*, which lived longer in wort than in sugar solution, and the asporogenic varieties of *Saccharomyces*, which lived longer in sugar solution than in wort; but even in these cases cultures lasted for many years. *Aspergillus glaucus* succumbed much more rapidly (within 2 years) than other *Aspergillus* moulds in sucrose solution. Thirty-one cultures of *Bact. aceti*, *B. Pasteurianum*, and *B. Kützingerianum* were all living after storage for 5—9 years in "double beer."—J. H. L.

Brewing. E. Kenward, Eltham. Eng. Pats. (A) 107,391 and (B) 107,538, Mar. 23, 1916. (Appl. Nos. 4352 of 1916 and 924 of 1917 respectively.)

(A) BEVERAGES of specific gravity not exceeding 1.017 and containing less than 2% of proof spirit, are prepared by boiling solutions of glucose (e.g., sp. gr. 1.020—1.030) with hops (e.g., 2—3 lb. per cwt. of sugar) and salt (e.g., 60 grains per gall.), diluting the cooled liquid with water sterilised by boiling, fermenting with a small quantity of yeast (e.g., 2 oz. per barrel) until the required alcohol-content has been attained, and then separating the yeast and dry-hopping the product (e.g., with $\frac{1}{2}$ —1 lb. of hops per barrel). Colouring and other matters may also be employed. (B) Light beers prepared in the usual manner are mixed with a proportion, e.g., 25%, of beverages produced as described above.—J. H. L.

Process for cleaning various materials [by means of enzymes]. Eng. Pat. 107,191. See 1.

XIXA.—FOODS.

Milk cultures : Substitute for litmus for use in —. W. M. Clark and H. A. Lubs. J. Agric. Res., 1917, 10, 105—111.

In preparing litmus-milk for use as a culture medium, difficulty is experienced in obtaining constant initial shades of colour. This was found to be due in part to the changes in hydrogen-ion concentration which milk undergoes during sterilisation, and in part to the effect which the impurities in litmus solution have on the hydrogen-ion concentration of the milk. Further, the litmus undergoes a temporary reduction during sterilisation of the medium, and time must be allowed for the colour to reappear. When the medium is used for cultures, change of colour may be due to reduction or to destruction of the indicator. To measure accurately the degree of acid or alkali formation, it is advisable to use an indicator which will be affected only by changes in hydrogen-ion concentration. It was found that dibromo-o-cresolsulphonphthalein or "bromeresol purple" fulfilled this condition. It is a definite chemical compound, obtainable in the crystalline state. For use, 0.5 gm. is ground to a fine powder, 14 c.c. of N/10 caustic soda is added, and the mixture stirred well and diluted, with shaking, to 100 c.c. Of this solution, 10 c.c. is added to a litre of milk. After sterilisation the colour of the medium is tea-green; alkali changes the colour to blue, acid to yellow.—J. H. J.

Saccharin ; Determination of — in foods. C. B. Gnadinger. J. Assoc. Off. Agric. Chem., 1917, 3, 25—32.

SACCHARIN is more readily extracted from a solution acidified with hydrochloric acid than from one acidified with acetic acid. The best solvents are ethyl acetate and ether; chloroform is unsuitable. In the provisional method of the Association (U.S. Bur. Chem. Bull., 107, 182) the sulphur is determined in the ethereal extract, and the amount of saccharin is calculated from the result. This method is not applicable to foods containing ground mustard, since sulphur compounds in the mustard are simultaneously extracted. These may be eliminated, however, by evaporating the extract, and treating the residue with petroleum spirit and then with bromine:—From 50 to 75 grms. of the material is digested for 2 hours, with occasional shaking, with about 200 c.c. of nearly boiling water, and then treated with 5 c.c. of glacial acetic acid and a slight excess of 20% normal lead acetate solution,

made up to 250 c.c. with cold water, left for 20 mins., centrifuged, and filtered. 150 c.c. of the filtrate is acidified with 15 c.c. of hydrochloric acid, and extracted for 2 mins. each time, with three successive portions of 80 c.c. of ether. The united extracts are washed with 5 c.c. of water and mixed with 10 c.c. of sand, and the ether is evaporated by the aid of bellows. When the residue is quite dry it is thoroughly mixed with 25 c.c. of petroleum spirit (b.pt. 30° to 65° C.), the extract decanted on to a filter, and the extraction repeated with two fresh portions of solvent. The residual sand is then washed with hot water and the washings filtered into a separating funnel. The filtrate (about 75 c.c.) is cooled, mixed with 7 to 8 c.c. of hydrochloric acid, and treated with an excess of bromine water. After 5 mins. the excess of bromine is removed by means of a slight excess of sodium nitrite solution, and the acid solution is extracted with three successive portions (50 c.c. each) of ether. The ethereal extract is washed with 5 c.c. of water, the ether allowed to evaporate spontaneously, and the sulphur in the residue is determined by fusion in a nickel crucible with sodium peroxide or with a mixture of sodium carbonate and potassium nitrate (6:1). The weight of barium sulphate obtained multiplied by 0.7814 gives the weight of saccharin, and to this should be added 0.5 mgrm. as a correction for the saccharin dissolved by the petroleum spirit. To prevent loss of sulphur through imperfect oxidation during the fusion, an electrolytic method may be used:—The residue from the ethereal extract is dissolved in hot water and filtered, and the filtrate and washings (about 75 c.c.) are mixed with 25 c.c. of 16% sodium hydroxide solution, and electrolysed for six hours with smooth platinum electrodes (area of anode about 120 sq. cm., and of cathode about 1 sq. cm.), by means of a current of 2.7 to 2.9 amps. The electrolysed solution is rendered slightly acid with hydrochloric acid, and the sulphuric acid is precipitated with barium chloride. A blank determination should be made to ascertain the amount of sulphur in the 25 c.c. of sodium hydroxide solution.—C. A. M.

Determination of theobromine. Radford and Brewer. See XX.

PATENTS.

Pastes ; Apparatus for desiccating alimentary —. S. Martinenghi, Milan, Italy. Eng. Pat. 104,866, Jan. 2, 1917. (Appl. No. 83 of 1917.) Under Int. Conv., Mar. 13, 1916.

THE apparatus consists of a wooden structure of two floors, in the lower of which the pastes are placed. An extraction fan is placed in the wall of the upper floor. The lower floor is divided into four chambers which communicate with the outer air through a grille with shutters, and with the upper floor by a passage at the side. The upper floor is divided into three chambers, one of which is the fan chamber, and the other two connect with it by a pivoted door, which enables first the one and then the other to be put in connection with the fan. One chamber has four openings in the roof which can be closed when required. When the fan is in operation, air is drawn in two directions alternately through the apparatus, entering either by the grille or by the openings in the top chamber. The apparatus is placed in a room which is closed, so that the same air is drawn through the apparatus during the whole process of drying.—J. H. J.

Bread and the like ; Manufacture of —. A. J. Jenkins, Hinckley, Leicestershire. Eng. Pat. 107,218, May 19, 1916. (Appl. No. 7181 of 1916.)

A SPECIAL mixture is prepared containing 12 lb.

of strong wheat flour, 2 lb. of maize flour, 4 oz. of sugar, and 8 oz. of common salt. 6 lb. of this mixture is made into a paste with 1 gall. of water at 150° F. (66° C.) and is allowed to cool to 80° F. (27° C.). This paste is added to a paste of 7 lb. of good strong white flour with $\frac{1}{2}$ gall. of water at 80° F. (27° C.), and the whole is kneaded into a dough, which is weighed into round tins with perforated sides and perforated domed bottoms. When the tins are in the "prover," steam is admitted at 50—60 lb. pressure, which is sufficient to permeate the dough. After treatment for 10—15 mins. at about 300° F. (150° C.), the dough has risen sufficiently for the tins to be removed to a baking oven.—J. H. J.

Sterilising and preserving foods; Apparatus for —. E. C. R. Marks, London. From Anchor Cap and Closure Corporation, New York. Eng. Pat. 107,396, Apr. 26, 1916. (Appl. No. 5099 of 1916.)

THE food is placed in glass jars or other form of container with covers sealed on under a vacuum. These are placed in a sterilising retort and a mixture of steam and compressed air is admitted into the retort until the temperature has reached 240° F. (116° C.) and the pressure is 30 lb. These conditions are maintained by the aid of a thermostat for a period of $\frac{1}{2}$ —2 hrs. A valve, operated by a differential pressure of 2 lb. between the air inlet and outlet valves, is provided to permit of the introduction of steam when the temperature falls. After sterilisation is completed, the steam is shut off and water suitably warmed is introduced to cool the containers. During cooling, the pressure in the retort is maintained with cold air. A modified form of the apparatus is also described.—J. H. J.

Food products; Apparatus for the treatment of liquid —. A. E. White, London. From Mojonnier Bros. Co., Chicago, U.S.A. Eng. Pat. 107,778, Apr. 14, 1916. (Appl. No. 5514 of 1916.)

THE apparatus is of glass and is of tube form, consisting of an expanded lower portion closed at the bottom and an expanded upper portion closed by a stopper at the top; these two portions are connected by a narrower portion. Either at or just above the level of the narrow portion is a draw-off tube with a stopcock. The bottom of the apparatus may be furnished with an opening closed by an adjustable stopper. Milk or a product from which fat is to be separated, together with the necessary reagents, is poured into the apparatus, which is then centrifuged, and the solution of fat obtained in the upper portion is run off by the side tube.—J. H. J.

XIXB.—WATER PURIFICATION ; SANITATION.

Algæ; Use of copper sulphate in the destruction of —. G. Embrey. Analyst, 1917, 42, 264—267.

IN the treatment of the water in reservoirs with copper sulphate to destroy algal growths and keep the water free from weeds, 1 part of copper sulphate per 3 million parts of water is sufficient, and this amount has no injurious effect on fishes. The number of bacteria present increases shortly after the addition of the copper sulphate, and then decreases, the increase appearing to be due to the decomposition of the algæ. The best way of adding the copper sulphate is to place the salt in a perforated copper tank fixed at the stern of a punt, so that the crystals fall through the holes as the punt passes through the water.—W. P. S.

Nitrous air; Antiseptic properties of —. H. Colin. Comptes rend., 1917, 165, 191—196.

THE observation was made by Priestley in 1772 that "nitrous air" has preservative properties. In his case the gas contained ordinary air, so that nitric acid was produced and acted as the preservative agent. If air is carefully excluded, nitric oxide has no germicidal action, even on delicate organisms, after several days' contact, but if air is admitted along with nitric oxide, the bacteria are killed. Cultures of *B. pyocyaneus* showed this action very well, owing to the presence of the pyocyanin; if the culture retained the blue colour during the experiment, the organism remained alive, but if the colour changed to brown, it was found that the organism had been killed.—J. H. J.

Lead arsenate; Rapid method for the determination of water-soluble arsenic in —. H. A. Scholz and P. J. Waldstein. J. Eng. Ind. Chem., 1917, 9, 682—683.

THE following method is used for factory control: 0.5 gm. of the dried powdered sample or 1 gm. of paste is weighed into a 250 c.c. volumetric flask, 200 c.c. of recently boiled water is added, boiled 3—5 mins., allowed to stand 10—15 mins., cooled, made up to 250 c.c., and filtered through a dry paper. 200 c.c. of the filtrate is treated with a few crystals of potassium iodide and 7 c.c. of concentrated sulphuric acid and evaporated to about 50 c.c.; it is diluted with cold water, made alkaline to methyl orange with sodium hydroxide, acidified with dilute sulphuric acid, treated with an excess of sodium bicarbonate, and then titrated with *N*/20 iodine solution. The results have been compared with those obtained by the A.O.A.C. method (24 hours at 32° C.) and either agree with or are slightly higher than the latter. The water-soluble arsenic is often largely in the arsenious form, and the arsenious oxide is precipitated with the lead arsenate in a form which is very difficult to wash out with cold water but dissolves readily in hot water; hence the higher results by the boiling method. Water-soluble lead is not found in more than traces. If the solution be evaporated until sulphuric acid fumes are given off, there is a loss of arsenic by volatilisation.—J. F. B.

Base-exchanging substances; Process for regenerating —. Staten Island Chemical Corporation, New York, Assignees of W. C. Foster, Rutherford, N.J., U.S.A. Eng. Pat. 101,207, June 23, 1916. (Appl. No. 8868 of 1916.) Under Int. Conv., Aug. 19, 1915.

A BASE-EXCHANGING substance, such as a zeolite, which has become inactive after use in a water filter, is treated with a 7% solution of sodium chloride, washed until free from chlorides, treated with a 1% solution of caustic soda until no more sodium is taken up, and then washed again. The substance is now ready for use again in a water filter. Base-exchanging substances with other bases than sodium, can be treated in the same manner with solutions of a like base.—J. H. J.

Sewage and other foul liquids; Apparatus for aerating —. R. Ames, Brighton. Eng. Pat. 107,937, Feb. 24, 1917. (Appl. No. 2725 of 1917.)

THE sewage is treated in a rectangular tank over which is a travelling carriage running on side rails and bearing a drum with a coil of flexible piping. One end of the piping is connected to an air compressor at the end of the tank, and the end

on the drum is connected to a horizontal pipe from which vertical pipes depend nearly to the bottom of the tank. Air diffusers, consisting of porous clay blocks in metal casings, are affixed to the ends of the vertical pipes. The sewage enters at the bottom of the tank by an inverted U-shaped pipe. An air-pipe connected to the compressor enters the upward limb of the U-shaped pipe; thus air can be passed into the sewage entering the tank, as well as into the sewage in the tank from the diffusers.—J. H. J.

Water; Apparatus for treating.—G. Ornstein, New York. Assignor to Electro Bleaching Gas Co. U.S. Pat. 1,233,371, July 17, 1917. Date of appl. May 9, 1913.

SEE FR. Pat. 469,275 of 1914; this J., 1915, 16.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Theobromine; Determination of.—N. Radford and G. Brewer. Analyst, 1917, 42, 274—276.

A QUANTITY of 0.25 gram. of the sample is dissolved in water and 5 c.c. of ammonia (sp. gr. 0.880), the solution is boiled and treated with a hot solution of 5 grms. of silver nitrate. If a precipitate forms it is redissolved by the addition of a small quantity of ammonia. The boiling is continued until the volume of the mixture is reduced to about 10 c.c.; before this stage is reached a dark coloured gelatinous precipitate forms. This precipitate is washed by decantation until free from silver, then collected on a filter, and the nitrogen in it determined by Kjeldahl's method. When 0.25 gram. of the sample is taken, the volume of N/10 hydrochloric acid neutralised is multiplied by 1.89164 to obtain the percentage quantity of theobromine present. The presence of considerable quantities of caffeine does not interfere with the determination.—W. P. S.

Uracil-cytosine dinucleotide. W. Jones and B. E. Read. J. Biol. Chem., 1917, 31, 39—45.

YEAST nucleic acid is composed of the groups of four mononucleotides joined together through their carbohydrate groups. When heated with ammonia it forms adenine-uracil dinucleotide by hydrolytic rupture of its central nucleotide linkage. When heated with mineral acid, the central nucleotide linkage is not attacked but the two terminal nucleotide linkages are broken and uracil-cytosine dinucleotide is formed. Uracil-cytosine dinucleotide produces both uracil and cytosine but neither guanine nor adenine. It likewise forms both pyrimidine nucleotides but neither of the two purine nucleotides, and yields no easily liberated phosphoric acid. When an aqueous solution of the dinucleotide is treated with an alcoholic solution of brucine, a brucine salt is formed which crystallises from hot water in microscopic individual needles having a composition corresponding to the formula,

—J. F. B.

Guanine mononucleotide (guanylic acid) and its preparation from yeast nucleic acid. B. E. Read. J. Biol. Chem., 1917, 31, 47—53.

GUANINE mononucleotide can be produced from yeast nucleic acid by the action of ferments and

this is the probable origin of the guanylic acid of animal glands. The same substance can also be prepared by heating yeast nucleic acid with ammonia, and since the hydrolysis is quite simple the guanylic acid may be obtained perfectly pure. 100 grms. of nucleic acid is heated with 530 c.c. of 2.5% ammonia at 115° C. for 1½ hours, and the product, after cooling, is treated with 530 c.c. of absolute alcohol and allowed to stand. The solution which contains adenine-uracil dinucleotide is filtered off, the precipitate consisting of the ammonium salt of guanine mononucleotide is repeatedly dissolved in hot water and reprecipitated with alcohol until a sample, on hydrolysis with sulphuric acid, is found to be free from adenine groups. To purify it, a concentrated solution of the mononucleotide in hot water is treated with ammonia, boiled and filtered, and then precipitated with lead acetate after acidification with acetic acid. The lead compound is decomposed with hydrogen sulphide, the filtrate evaporated at 45° C. under reduced pressure to a small volume, and the guanine mononucleotide precipitated with alcohol. It forms a brucine salt melting at 203° C. and has been completely identified with the guanylic acid from ox pancreas.

—J. F. B.

Succinic acid; Determination of.—E. C. Grey. Bull. Soc. Chim., 1917, 21, 136—141.

THE present method of separating succinic acid from other acid products of fermentation, based on Pasteur's method, is to add to a concentrated aqueous solution of the calcium salts of the acids sufficient alcohol to bring the concentration of the alcohol to 85%, at which strength calcium succinate is insoluble. Calcium is estimated in the precipitate, and from the result the amount of succinic acid is calculated. This method is liable to several errors, due to the solvent action of 85% alcohol on calcium succinate if peptone is present, the presence of substances preventing the crystallisation of calcium succinate, the presence of traces of acid in the alcohol employed, the loss on washing the precipitate, and the loss of succinic acid from the aqueous solution during concentration. The following process avoids these sources of error:—The mixture of acids produced by the fermentation is distilled in steam to remove volatile acids, and the remaining acids are extracted by ether, dissolved in hot water, and neutralised with calcium carbonate. A few drops of phenolphthalein is added, and sufficient lime water to keep the liquid red. The solution is kept warm for one hour to ensure the complete conversion of the lactone of lactic acid to calcium lactate, and is then filtered into a 200 c.c. flask. The calcium corresponding to the total acids is estimated in 50 c.c. of the filtrate. Another portion of the filtrate is slowly concentrated to 13 c.c. in a long-necked flask heated in an oven to just over 100° C. The volume is then made up to 110 c.c. with 96% alcohol, and the flask is well shaken and allowed to stand until the precipitate becomes crystalline. The solution is filtered, and the amount of calcium in 100 c.c. of the filtrate, multiplied by 1.1, gives the amount of calcium present as soluble salts in the portion of the original filtrate taken. The difference between the calcium equivalent of the total acids and the calcium equivalent of the soluble salts, gives the calcium equivalent of the succinic acid present. Figures are given to show that loss of succinic acid occurs from an alkaline solution of calcium lactate when evaporated in an open dish on the waterbath, and also to show the influence of peptone in preventing the complete precipitation of calcium succinate by 85% alcohol. Glycerin also causes an error, though smaller, but glucose does not interfere.—F. Sp.

Nitriles from amines with the same number of carbon atoms; Formation of—. P. Sabatier and G. Gaudion. *Comptes rend.*, 1917, **165**, 224—227.

SABATIER and Senderens in 1905 found that finely divided nickel at 200° C. is an effective catalyst for converting nitriles into amines in accordance with the equation: $R.CN + 2H_2 = R.CH_2.NH_2$. The reverse reaction, $R.CH_2.NH_2 = 2H_2 + R.CN$, has now been effected by the authors. When the vapour of benzylamine (b.pt. 185° C.) is passed over nickel at 300°—350° C., benzonitrile is formed, but the hydrogen set free reacts with the original amine forming toluene and ammonia, scarcely any hydrogen escaping in the form of gas. The reaction may be represented by:

one-third of the benzylamine being converted into benzonitrile. Isoamylamine, by a similar reaction, yields isovaleronitrile (b.pt. 129° C.), together with isopentane. Part of the latter is decomposed by the nickel with deposition of carbon and liberation of hydrogen, which gas is rendered luminous by the isopentane present in it. If copper is substituted for nickel, a temperature of 300°—400° C. is necessary and the products are much more complex.—A. B. S.

Glutamic acid; Process of separating— from other amino acids. A. Corti, Dübendorf, Switzerland. Eng. Pat. 106,981, Apr. 7, 1916. (Appl. No. 16,015 of 1916.) Under Int. Conv., Apr. 7, 1916.

THE acid solution obtained after hydrolysis of albumins is filtered hot and then sufficient alkali or alkaline-earth hydroxide or carbonate is added to neutralise both the free hydrochloric acid and that combined with the amino acid, leaving the amino acid unaffected. When the liquid has cooled and stood for some days, the glutamic acid is separated by filtration or by centrifugal action and purified from resinous matter by recrystallisation from water and decolorised with charcoal. Other amino acids can be obtained by treatment of the mother liquors.—L. A. C.

Alkaloids of the morphine group; Manufacture of compounds of—. O. Imray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 107,409, June 24, 1916. (Appl. No. 8915 of 1916.)

ALKALOIDS of the morphine group, or their derivatives, are caused to react in equimolecular proportions with CC-diallylbarbituric acid, a CC-allylalkylbarbituric acid, or a CC-dialkylbarbituric acid, giving well crystallised compounds with valuable therapeutic (soporific or sedative) properties.—L. XXIII.—ANALYSIS.

Acetates; Inadequacy of basic ferric acetate test for—. L. J. Curtman and B. R. Harris. J. Amer. Chem. Soc., 1917, **39**, 1315—1317.

IN carrying out the basic ferric acetate test for acetates, a definite volume of a standard solution of sodium acetate was diluted to about 20 c.c. and made alkaline to phenolphthalein with 1% caustic soda solution. The pink coloration was removed with 1:10 hydrochloric acid. One c.c. of ferric chloride solution was added, the solution diluted to 50 c.c., boiled vigorously for 2 minutes and filtered; a reddish-brown residue indicates presence of acetates. Parallel experiments in which the final dilution was made to 200 c.c. and varying the concentration of the ferric chloride solution, i.e., 5—25 mgrms. Fe per c.c., showed that the test as conducted above was not sufficiently sensitive, that excessive dilution was not desirable, and that increasing amounts of iron tended to diminish the sensitiveness. A series of experiments in presence of sodium chloride in solution and using ferric chloride containing hydrochloric acid in varying amounts corroborated the above conclusions. Contrary to anticipation, the test did not furnish even a rough means of estimating the amount of acetate present.—J.H.P.

Molybdenum residues; Recovery of—. V. Lenher and M. P. Schultze. J. Ind. Eng. Chem., 1917, **9**, 684—685.

THE method consists in the precipitation of molybdenum sulphide by means of hydrogen sulphide from a solution slightly acid with nitric acid, or the formation of a sulphomolybdate solution by treating the alkaline solution of the "yellow precipitate" with hydrogen sulphide and acidifying with hydrochloric acid to precipitate the molybdenum sulphide. The latter on ignition gives MoO_3 which is in a condition to be used again. The waste molybdate liquors are usually strongly acid with nitric acid and should either be largely diluted or partially neutralised with sodium hydroxide so that the acidity is between 0.1 and 0.4%. The solution is slightly heated and hydrogen sulphide passed through. The supernatant liquor is siphoned off, the sulphide washed with water, collected, dried, and roasted. When much iron is present the washing water should be acidified with hydrochloric acid. The "yellow precipitate" may be dissolved in sufficient sodium hydroxide to make a solution which is slightly alkaline to phenolphthalein; any ferric hydroxide is filtered off. The filtrate is diluted and saturated with hydrogen sulphide. Excess of dilute hydrochloric acid is added and the molybdenum sulphide separated.—J. F. B.

Gas fillers [for gas analysing apparatus]. Aktiebolaget Ingeniörsfirma F. Egnell, Stockholm. Eng. Pat. 104,880, Mar. 14, 1917. (Appl. No. 3740 of 1917.) Under Int. Conv., Mar. 2, 1916.

THE pipe leading from a gas conduit, *e.g.*, a boiler flue, to a gas analysing apparatus projects into the gas conduit and terminates in an open receptacle, preferably funnel-shaped, containing suitable filtering material such as sand. The receptacle is carried by a protective cylinder enclosing the pipe. —W. F. F.

Gas-testing apparatus. H. R. Webster, Horsforth, Yorks. Eng. Pat. 107,811, July 12, 1916. (Appl. No. 9798 of 1916.)

In a gas-testing apparatus suitable for detecting and indicating the presence and proportion of carbon dioxide in flue gases of boiler furnaces or recovery plants, a cartridge of chemical absorbent is supported centrally within a closed porous cylinder upon a bottom closing plate, the cylinder being surrounded by filtering material. The gas diffuses into the cylinder and the amount absorbed is measured by a graduated U-tube pressure gauge. In a modification, the porous vessel is enclosed within a metal casing, the gas to be tested being circulated in the annular space between the two by a steam injector. In this case the filtering material is contained in a separate vessel through which the gas is first drawn, and the liquid vacuum gauge tube is connected with the porous vessel and with a closed liquid container below. The space above the surface of the liquid in this container is connected by a pipe to the gas space outside the porous vessel so as to equalise the pressures. In another modification the space within the porous cylinder is closed at the bottom by an elastic diaphragm which actuates an indicator to show the decrease in pressure within the cylinder. —W. F. F.

Metals and other solid materials: Appliances for ascertaining the hardness of —. Rudge-Whitworth, Ltd., and J. V. Pugh, Coventry. Eng. Pat. 107,685, Aug. 12, 1916. (Appl. No. 11,396 of 1916.)

In a device for testing the hardness of materials

by the depth of the indentation in the material, *d*, caused by the predetermined pressure of a hardened ball, the ball is carried at the end of a sliding spindle, *l*, pressed forward by a spring, *g*. The spindle is provided with a collar, *k*, which

abuts against a fixed bush, *i*, through which the ball projects a predetermined distance. The tension of the spring is adjusted by the screwed cap, *p*, and when the resilient resistance of the ball is overcome, any further pressure is taken between the bush, *i*, and the adjacent area of the material under test. —W. F. F.

Official Notices.

IMPORT RESTRICTIONS.

The following Rulings and Decisions (Notification No. 13) respecting prohibitions of importation have been arrived at by the Department of Import Restrictions:—

Prohibited. "Bludtan" powder extract (chestnut extract). Blue powder. Cadmium. Cellulose acetate film scrap. Chromel resistance wire. Congo copal. Distilled waters. Manila copal. Nickel-chrome ribbons. Jasmin oil. Perfumed spirit. Phosphor bronze sheets. Quartz, fine and rough. Reclaimed rubber. Rubber scrap or waste. Selenium. Soap, hand cleanser, or pumice. Sodium selenite. Neutral spirit. Non-alcoholic wine.

Not prohibited. Acetone, ehlersulphonic acid. "Alumen of chrome." Aluminium flake. Amyl acetate. Antimony regulus. Ardolite. Arkansas powder (for polishing). Arsenate of lead. Balata, raw. Balsam, Canada. Balsam, Copaiba. Barium hydrate. Benzyl benzoate. Bog ore. "Boro-carbone." Boron-copper alloys. "Bromo acid." Camphor, Formosa. Carbon tetrachloride. Cellulose acetate. Chinese wood oil. Citron essence. Civet. Cocaoline. Colluputin. Copal varnish, not containing spirit. Copra. Copra meal. Cream of tartar. Cutch cake. Dyes:—Erythrosine, Methyl violet, Paraphenylenediamine. Ebonite containing less than 50% rubber. Elastic bitumen or "Elatrite." Ozone generators, complete. Ferment "D." Furnaces, electric, complete. Fusel oil. Gelatin emulsion, used in making photographic paper. Glass cotton. Glucose. Glycerin substitute (mainly glucose). Glycerophosphates. Grape juice, unfermented and non-alcoholic. Graphite paste. Gum Damar. Hematine (paste and solid). Hydrate of alumina. Indigo. Ink paste. Kamanga oil. "Kromoid" wax for tanners. Lead acetate. Lime juice, raw. Liquorice juice in blocks, mass and sticks, containing no added sugar. Litho red (Aniline dye). Maltose, made from rice. Mangrove bark. "Mercury gas." Metol. Mimosa bark. Moellon. Molasses. Myrabolams. Nitrate of soda. Oils:—Bean, chaulmoogra, Chinese wood, cod, fish, mixed fish, herring, kamanga, kernel, olive, peanut, salad, sardine, shark. "Paxolin" insulating material. Peanut butter or paste. Petroleum jelly, vaseline. Phthalic anhydride. Pitch, petroleum. Pitch, vegetable. Pituitary glands of animals. Platinum lustre, liquid. Potassium bromide. Protoxide of sodium. Pyrometers. "Raylux" (chemical decoloriser). Red gum acroïdes or yacca gum. Rock crystal. Rosin. Salicylic acid. Salol. Soda ash. Soldering flux. Soya cake. Starch, potato and sweet potato. Sugar syrup, cane, as molasses. Sulphate of alumina. Sumac, dried leaves for tanning. Tar, vegetable. Tetrachloride of titanium (liquid). "Thiol" (tar product). Tungsten. Turmeric. Vapo-cresolene. Vulcanite, containing less than 50% of rubber. Zinc powder. Zirconia.

General licence. Abrasive cloths. Electrodes. Filter candles and filter cylinders for water. Manufactures of gummite. Medicinal preparations containing sugar. Rennet, dry and extracts.

PATENTS, TRADE MARKS AND DESIGNS. FEES.

A Licence was granted by the Board of Trade on 7th December, 1915, permitting in certain

circumstances the payment of fees and agents' charges and expenses in respect of patents, trade marks and designs, payable in an enemy country or on behalf of an enemy.

The Board, under date Sept. 5, 1917, has amended this Licence as follows:—

(a) The words "person" or "persons" respectively wherever they occur in Clauses 1 and 2 thereof shall mean a person or persons being of British, Allied or Neutral nationality:

(b) In Clause 1 (b) and 2 (b) of the Licence there shall be added immediately after the words "His Majesty's Dominions" wherever they occur, the words "or of Allied territory not in hostile occupation."

The following provisos are added:—

Provided always that as regards payments on behalf of an enemy under Clause 2 of the said Licence as amended hereby, the same may only be made by the person making the same, out of moneys (a) remitted by or on behalf of such enemy, or (b) held for or on account of such enemy, and subject to the provisions of the next paragraph, nothing in the said Licence or herein shall permit any payments to be made on behalf of an enemy by way of gift or by way of advancement or loan to or on account of such enemy:

Provided also that nothing herein contained shall prevent persons of British, Allied, or Neutral nationality residing, carrying on business or being in the United Kingdom who have an interest in or under a patent or design belonging in whole or in part to an enemy from paying out of their own moneys fees payable in the United Kingdom for obtaining the renewal of such patent or for obtaining the renewal of the registration of such design or from paying agents in the United Kingdom (including themselves) their charges and expenses (if any) in relation to such matters.

DEALINGS IN LEAD AND LEAD COMPOUNDS.

The Minister of Munitions has made an Order, dated 1st September, whereby:—

1. He takes possession as from 1st September, until further notice, of all pig lead, whether virgin or remelted, old and scrap lead and lead residues, now or hereafter situated in the United Kingdom, subject to the following exceptions:—(a) All such lead as may be in the possession of or due under an existing lawful contract in writing for future delivery to a manufacturer for use in such manufacturer's own works; (b) all such lead as may be specially excepted under the written authority of the Minister of Munitions. The lead of which possession is taken will, until further notice, be paid for by the Minister of Munitions on delivery: as to virgin pig lead at the prices specified in the Schedule below; and as to remelted, old and scrap lead and lead residues, upon terms which will be communicated in due course to the various owners.

2. If any person having control of any lead of which possession has been taken under Clause 1, without the consent of the Minister of Munitions sells, removes or secretes it, or deals with it in any way contrary to any conditions imposed in any licence or permit that may be granted in respect thereof, he will be guilty of an offence against the Defence of the Realm Regulations.

3. All existing licences issued by or on behalf of the Minister of Munitions for dealing in any remelted, old or scrap lead or lead residues are cancelled.

4. No person shall, as from 1st September, until

further notice, purchase, sell, offer to purchase or sell, or, except for the purpose of carrying out a contract in writing existing prior to 6th April for the sale or purchase of white lead, lead oxides, lead manufactures, lead alloys or lead compounds of any kind, or a contract in writing existing prior to 2nd February for the sale or purchase of any other kind of lead, enter into any transaction or negotiation in relation to the sale or purchase of lead situated outside the United Kingdom, except under and in accordance with the terms of a licence issued under the authority of the Minister of Munitions.

5. No person shall as from 1st September, until further notice, offer to purchase, purchase or take delivery of any lead situated in the United Kingdom except under and in accordance with the terms of a licence issued under the authority of the Minister of Munitions, or offer to sell, sell, supply or deliver any such lead to any person other than the holder of such a licence, and in accordance with the terms thereof, provided that no such licence shall be required in the case of any offer to sell or purchase, sale, purchase, or delivery of such lead:—(a) For the purpose of a contract or order for the time being in existence, certified to be within Class "A" in the Order of the Minister of Munitions as to priority, dated 8th March, 1917, and made in substitution for Circular L. 33, or certified by or on behalf of the Minister of Munitions to be within Class "B" of the said Order. (b) For the purpose of necessary repairs or renewals requiring immediate execution and for which no other metal can be substituted, and requiring for the entire carrying out thereof the use of not exceeding 1 cwt. of sheet lead or lead pipe and not exceeding 28 lb. of solder and no other lead, and in respect of which repairs or renewals the purchaser shall have given to the seller at or before the time of purchase a declaration in writing specifying the nature of the work for which the same is required, and the place where the same is to be carried out, and that the lead purchased is for the purpose mentioned in this sub-clause and for no other purpose.

6. No purchase or sale of lead situated in the United Kingdom, or offer to purchase or sell any such lead, whether such purchase, sale, or offer is or is not under any licence issued under the authority of the Minister of Munitions, shall, in the case of any class of lead specified in the Schedule below, until further notice, be at a price exceeding the price set opposite the same in the said Schedule.

7. No person shall as from 1st September, until further notice, use any lead for the purpose of any manufacture or work except:—(a) For the purpose of a contract or order for the time being in existence certified to be within Class "A" of the Order of the Minister of Munitions as to priority dated 8th March, 1917, and made in substitution for Circular L. 33, or certified by or on behalf of the Minister of Munitions to be within Class "B" of the said Order. (b) For the purpose of necessary repairs or renewals requiring immediate execution, and requiring for the entire carrying out thereof the use of not exceeding 1 cwt. of sheet lead or lead pipe, and not exceeding 28 lb. of solder and no other lead. (c) For the purpose of type-casting from metal already in the form of type on the 2nd February, 1917, or from lead purchased for that purpose prior to that date. (d) Under and in accordance with the terms of a licence issued under the authority of the Minister of Munitions.

8. All persons shall, within seven days from the first day of each month, send in monthly returns of:—(a) All lead held by them in stock or otherwise under their control on the last day of the preceding month, the lead actually in stock to be shown separately. (b) All lead purchased or sold by them for future delivery and not yet delivered

on such last day. (c) All lead delivered to them during the preceding month. (d) All contracts or orders existing on the last day of, or entered into during, the preceding month requiring for their execution the use of lead for any purpose, specifying the amounts of lead required monthly for the purposes of such contracts or orders, and distinguishing between the amounts required for work certified to be within Class "A" in the said Order of 8th March, and the amounts required for other purposes, or certified by or on behalf of the Minister of Munitions to be within Class "B" of the said Order. No return is required from any person whose total stock of lead in hand and on order for future delivery to him has not at any time during the preceding month exceeded 1 cwt.

Returns shall as regards remelted, old and scrap lead and lead residues, be sent in to the Director of Materials, AM2/ES Hotel Victoria, Northumberland Avenue, London, W.C.2, and as regards all other kinds of lead, to the Director of Materials, AM2/E Hotel Victoria, Northumberland Avenue, London, W.C.2.

9. For the purpose of this Order the expression "lead" shall mean pig lead, whether virgin or remelted, sheet lead, lead pipe, and old and scrap lead, lead residues, white lead, whether dry, in oil, or prepared for use, lead oxides, lead manufactures, lead alloys and lead compounds of every kind, or any of them.

10. All communications on the subject of remelted, old or scrap lead or lead residues shall be addressed to the Director of Materials, AM2/ES Hotel Victoria, Northumberland Avenue, London, W.C.2, and marked "Scrap Lead."

All applications for licences to purchase lead other than remelted, old or scrap lead or lead residues, shall be made to the Director of Materials, AM2/E Hotel Victoria, Northumberland Avenue, London, W.C.2, and marked "Lead Licence"; and all applications to use lead other than remelted, old or scrap lead or lead residues shall be made to the Controller, The Priority Department, 1, Caxton Street, Westminster, S.W.1.

11. The Order of the Minister of Munitions, dated 6th April, 1917 (this J., 1917, 408), relating to certain classes of lead is cancelled, except clause 8 thereof, but such cancellation shall not affect the previous operation of that Order or the validity of any action taken thereunder, or the liability to any penalty or punishment in respect of any contravention or failure to comply with the same prior to its cancellation, or any proceeding or remedy in respect of such penalty or punishment.

Schedule. Maximum prices.

Virgin pig lead, £29 per ton c.i.f.; £30 per ton ex store or ex refiners' works. Manufactured lead—Sheet lead, £39 10s. per ton, lead pipe, £40 per ton, delivered United Kingdom, less 2½% monthly account, the usual trade extras and allowances to apply. The rate of exchange between chemical houses and manufacturers of chemical sheet lead, for the old lead in pig lead shape, to be £8 per ton net for sheet lead, and £8 10s. per ton net for lead pipe, the manufacturer paying cost of delivery of the old lead; the sheet lead or lead pipe to be delivered United Kingdom. The usual trade extras to apply.

Lead compounds. Dry white lead, £16 per ton, less 5% monthly account delivered United Kingdom. The usual trade extras and allowances to apply. White lead in oil, £53 per ton less 5% monthly account for deliveries in packages of 5 cwt. and over, and £55, less 5% monthly account for lots of less than 5 cwt. White lead in packages less than 5 cwt. to be charged at the customary trade extra for packing. These prices for white lead in oil are based on a price of £50 per ton as the spot price for raw linseed oil in barrels. If

the average daily spot price of raw linseed oil during the preceding month rises or falls by multiples of £6, then the above maximum price of white lead in oil shall rise or fall by 10s. per ton for every £6 per ton rise or fall in the price of linseed oil. Red lead and litharge, £12 per ton, less 2½% monthly account in 5 cwt. casks delivered United Kingdom. The usual trade extras and allowances to apply.

RESTRICTIONS ON USE OF FLOUR FOR CERTAIN PURPOSES.

The Food Controller has, under Article 10 of the Flour and Bread (Prices) Order, 1917, determined that the following are purposes for which a person shall not, after the 15th September, 1917, take delivery of any flour except under and in accordance with the terms of a licence granted to him by or under the authority of the Food Controller:—Cake mixtures, baking powders, egg powders, blancmange powders, custard powders, Italian pastes, soup squares or pastes, macaroni, spaghetti, sweet manufacture, chocolate and cocoa powders, infants' and invalids' foods, mustard, spices, condiments, and all such preparations. The effect of this decision is to put the use of flour for the purposes named on the same footing as the use of flour for wholesale biscuit manufacture, industrial purposes, ships' stores, etc., and any person desiring to use flour for the purposes named must apply to the Ministry of Food (Flour and Bread Section), Palace Chambers, Westminster, London, S.W.1, for a licence which, if granted, will be issued on payment of the sum of 18s. per 280 lb.

CENSUS OF STOCKS OF OILS, FATS, ETC., IN FRANCE.

A French Presidential Decree, dated 4th September, is to the effect that all producers, owners, holders, or any one having charge of stocks exceeding 1000 kilos. (about 2205 lb.) of oleaginous seeds and fruits of all kinds; vegetable or animal fats and oils, pure or mixed; fatty acids; glycerin and liquids containing glycerin ("eaux glycéreuses"); soap and candles; shall before the 1st October next make a declaration of their holding of any of the foregoing articles on midnight of 15th September.

FRENCH COMMITTEE TO CONTROL CHEMICAL, PHARMACEUTICAL AND PHOTOGRAPHIC PRODUCTS, COLOURS, PERFUMES, ETC.

A French Presidential Decree, dated the 27th August, appoints a Committee to examine questions relating to the trade in, and industrial use of, chemical products, colouring materials, pharmaceutical products, photographic products, perfumes, etc. The Committee, which will be known as "Le Comité des Produits Chimiques," will ascertain, co-ordinate, and control the requirements of the State and of the public, and the means of meeting those requirements, and its functions include questions of priority in regard to purchase, transport, and manufacture, and of the import and export of the goods in question, and accumulations of stocks. In the case of goods included in the lists contained in Decrees to be issued by the Minister of Commerce, the functions, in regard to import prohibitions, conferred by Article 3 of the Decree of the 22nd March on the "Comité des Dégagements aux Prohibitions d'Entrée" are permanently

delegated to the "Comité des Produits Chimiques." This Committee is also empowered to advise on applications for export licences submitted to the "Commission des Dégagements aux Prohibitions d'Exportation." (See also this J., 1916, 1247.)

Annual Meeting.

Paper read on Thursday, July 19th, 1917.

PROF. HENRY LOUIS IN THE CHAIR.

CONSTRUCTIONAL STEELS AND THEIR HEAT TREATMENT.

BY FRED. C. A. H. LANTSBERRY, M.S.C.

For the purposes of this paper steels are to be regarded essentially as alloys of carbon with iron. In the processes of manufacture silicon and manganese are added for well-known reasons; the amount of the former element added in this way seldom exceeds 0.15%, while that of the latter usually runs from 0.2 to 0.6%.

Alloy steels are simply steels to which other elements or an excess of silicon and manganese have been added for some specific reason. Until about twenty years ago alloy steels were practically never used except for some highly special engineering work. The introduction of high speed engines, however, brought about the setting up of stresses, simple and compound, dynamic and static, which the plain steels, in their conditions as then known, were incapable of withstanding. Resort was then made to the addition of various alloying elements to the steels with the object of improving their mechanical properties. Improvements in electrical machinery and new appliances demanded the improvement of magnet steels. Further, the introduction of harder steels increased machining difficulties and consequent improvements were necessitated in cutting tools. At the present time the following elements are added to steels for some purpose or other:—Chromium, tungsten, nickel, silicon, manganese, vanadium, molybdenum, cobalt, titanium.

When originally introduced, alloy steels owed their merit to superior mechanical properties in their manufactured state. The superiority of mechanical properties was often more imaginary than real. It was soon discovered that by heat treating these steels, still further improvements in their mechanical properties could be effected, and it became apparent to metallurgists that the full value of the alloying element was only obtained after some process of heat treatment. This knowledge has only been made use of to any extent within the last few years, and even at the present time much alloy steel is used in its crude state when the cheaper plain steel will serve equally well.

Here it might be of advantage to give a few definitions:—

Annealing consists in heating a steel to a temperature above the critical range and allowing it to cool slowly through this range.

Hardening implies very rapid cooling from temperatures above the critical range.

Tempering consists in heating a hardened steel to some temperature below the carbon change point, known to metallurgists as A₁.

Heat treatment consists of a combination of the two latter processes.

The simple steels used for constructional purposes contain anything from 0.1 to 0.75% carbon. In the annealed state their mechanical properties are to all intents and purposes rectilinear functions of the carbon content and are included within the limits:—Yield stress, 16–45 tons per sq. in.;

ultimate stress, 20—65 tons per sq. in.; contraction, 70—30%. The elongation is so largely a function of the shape and relative dimensions of the test piece that no useful purpose is obtained by quoting it.

Alloy steels for structural purposes are divided up as follows:—Nickel steels, nickel chrome steels, chrome vanadium steels, manganese steels.

Nickel steels may be divided into two classes:—(1) Low carbon steels with 0.1 to 0.15% C. (2) Medium carbon steels with 0.3 to 0.6% C. The usual content of nickel is 3 to 4%, but in the case of the mild steels the nickel is sometimes made as high as 6.5%. Some makers produce nickel steels with a content as low as 1.0%, but it is very doubtful if steels containing below 2.5% of nickel possess any advantages over ordinary carbon steels.

Low carbon nickel steels are invariably used for case-hardening purposes. Their treatment consists in heating to temperatures in the region of 900° C. in some carbonising mixture for a period of time depending on the depth of case required and the size. The articles are re-heated to 900° C., quenched, and again re-heated to 780° C., and quenched in water or oil according to the degree of hardness required in the case. The reason for this twofold quenching is that in a case-hardening material we have to deal with a composite bar. After treatment the core of the steel has a yield stress of about 55 tons per sq. in. and an ultimate stress of 75 tons per sq. in., with a reduction of area of 55%, compared with 25 tons, 33 tons, and 65% respectively in the untreated condition.

Medium carbon nickel steels are very largely used in constructional engineering. Their method of treatment consists in heating to 800° C. and quenching in oil, followed by re-heating to a temperature not exceeding 725° C., according to the particular mechanical properties required. In the normal state an average steel will have the properties:—Yield stress, 28 tons per sq. in.; ultimate stress, 45 tons per sq. in.; contraction, 40%. By heat treating these properties can be varied within the limits:—Yield stress 28 to 100 tons per sq. in.; ultimate stress, 50 to 100 tons per sq. in.; contraction 60 to 40%.

Simple chromium steels are seldom used; chromium is usually added in conjunction with either nickel or vanadium.

Chrome nickel steels may be divided into two classes:—(1) Steels requiring quenching to attain hardness. (2) Air-hardening steels.

The first class contains C, 0.3 to 0.45%; Cr, 0.5 to 1.5%; Ni, 1.0 to 3.0%. This steel is treated by oil quenching from 800° C. and tempered according to the mechanical properties required. These can be varied between the following limits:—Yield stress, 35 to 125 tons per sq. in.; ultimate stress, 50 to 130 tons per sq. in.; contraction, 60 to 0%. It will be seen that the variations which can be obtained in the mechanical properties of these steels are enormous and this fact should make them the most widely used of the alloy steels. Unfortunately, however, they are not at all amenable to machining operations under the conditions now in vogue.

Air-hardening steels contain C, 0.25 to 0.35%; Cr, up to 0.15%; Ni, 5.5 to 3.5%. They are treated by heating to 800° C. and allowing to cool in the air. So treated a well-known air-hardening steel has the mechanical properties:—Yield stress, 85 tons per sq. in.; ultimate stress, 116 tons per sq. in.; contraction, 45%. These properties can be further varied by tempering. Experience has shown that better and more uniform results can be obtained by oil-quenching and tempering, but the advantage of air-hardening lies in the avoidance of the distortion which invariably occurs during quenching operations.

Chrome-vanadium steels are used containing C, 0.3 to 0.6%; Cr, 0.5 to 1.5%; V, up to 0.3%. These

steels are used very largely in America but to nothing like the same extent in other parts of the world. Their heat-treatment consists in quenching from 800° C. followed by tempering according to mechanical requirements. The variations in properties which can be obtained are:—Yield stress, 35 to 100 tons per sq. in.; ultimate stress, 45 to 120 tons per sq. in.; contraction, 70 to 25%. These steels possess the great advantage of machining fairly readily.

Manganese steels have been exhaustively dealt with in the numerous researches of Sir Robert Hadfield and his collaborators. They present great difficulties in machining and are only used for highly special purposes.

It is evident from this brief review that the mechanical properties of alloy steels can be varied within wide limits by heat-treatment and the question "how do plain carbon steels respond to heat-treatment?" naturally arises.

By oil-quenching and tempering the mechanical properties of a 0.5% carbon steel can be varied between the limits:—Yield stress, 25—87 tons per sq. in.; ultimate stress, 40—102 tons per sq. in.; contraction, 50—0%. Similarly the properties of a 0.75% carbon steel can be varied as follows:—Yield stress, 45—100 tons per sq. in.; ultimate stress, 65—120 tons per sq. in.; contraction, 45—0%. It is obvious, therefore, that the mechanical properties of ordinary carbon steels can be vastly improved by heat-treatment so that they could be made suitable for purposes for which alloy steels are used at present. In this note, however, only static tests have been dealt with, and it is in resistance to dynamic stresses that alloy steels show up to the greatest advantage. Some notion of the way in which a steel will behave under shock can be obtained from the value of the reduction of area given in the ordinary tensile test. Generally speaking, the higher the contraction the greater will be the resistance to shock. It will be noticed from the examples given above that for equal yield and ultimate stress an alloy steel will always have a greater reduction of area than the corresponding plain carbon steel.

London Section.

Meeting held at Burlington House, Monday, April 2nd, 1917.

BY MR. A. R. LING IN THE CHAIR.

THE ACTION OF NITRIC ACID ON CASTOR OIL.

BY R. BRIGHTMAN, M.Sc., A.I.C.

Nitrated castor oil is briefly mentioned by J. Lewkowitsch in his treatise on "Oils, Fats, and Waxes," Vol. III., p. 194, and its properties and industrial applications have been dealt with in a paper by W. F. Reid (this J., 1899, 972). No account, however, is given, either of the nature of the nitration, or of the chemical character of the nitrated oil, although Reid suggested that in the nitration the glyceride was split up, and that the glycerol was then decomposed, but he admitted that he was not sure what followed. The following research was carried out in order to throw light on these two points—the process of nitration and the chemical nature of the nitration product.

Lewkowitsch stated that nitrated castor oil could be obtained by treating castor oil with a mixture of nitric and sulphuric acids, exactly as in the nitration of glycerin. The reaction, however, is a very violent one, and the product itself

appeared liable to spontaneous decomposition on a slight rise of temperature. Several attempts were made to effect the nitration with a mixture of nitric and sulphuric acids. Various proportions of the acids were used, and the oil was added in small quantities to the well-cooled acid mixture. Even with the most rigorous cooling, both of the oil itself and of the acid mixture, the reaction always sooner or later became extremely violent and a charred mass was left. This was the case even when the nitrating mixture was cooled in a freezing mixture of snow and salt and the whole operation conducted in an open shelter at 40° F. (4.5° C.).

The procedure was then varied by first sulphonating the castor oil and then treating the sulphonated oil with nitric acid, hoping to replace the sulphonic group with the nitric acid group. These experiments, however, proved no easier to control than the first series, but tended to show that the violence of the reaction was due to the presence of the sulphuric acid.

To test this, an experiment was performed in which the sulphuric acid was replaced by acetic acid. A mixture of equal volumes of fuming nitric acid (sp. gr. 1.51) and glacial acetic acid was cooled to 15° C. and the castor oil slowly added, with thorough agitation, the temperature being maintained at about 15° C. The reaction proceeded without violence, and after standing over-night the mixture was poured into excess of cold water. A lemon-yellow oil collected at the bottom of the beaker. This oil was washed with dilute alkali and with water. After draining, the oil was dissolved in acetone, the solution filtered, and the acetone distilled off on the water-bath. The residual oil was then dried in a current of air. The product thus obtained was a reddish-brown viscid oil with a characteristic smell. It was easily soluble in acetone and ether but was insoluble in carbon bisulphide. It was easily recognised as a nitrated castor oil. This experiment indicated that not only was sulphuric acid unnecessary for the nitration of castor oil, but also that the violence of the reaction was due, at least in part, to the presence of this acid. An attempt was therefore made to effect the nitration with dilute nitric acid. The attempt was successful and it was found that under the proper conditions nitrated castor oil is easily obtained by the action of dilute nitric acid on castor oil.

Nitrated castor oil was obtained by this process, after purification, as a reddish-brown viscid oil with a characteristic smell. It is easily soluble in acetone, ether, alcohol, and acetic acid, but is insoluble in carbon bisulphide. The oil is somewhat heavier than water, its sp. gr. being about 1.05. It does not decompose at 100° C. but slowly darkens on keeping in the warm.

The analytical investigation of the nitrated oil was attended with some difficulty. Attempts to determine the saponification value met with unsatisfactory results. The end point could not be accurately ascertained for lack of a reliable indicator, the colour of phenolphthalein being masked by the dark-brown colour of the saponified oil. On acetylation the oil gave a dark, viscid, resinous mass unsuitable for quantitative work. The attempt to determine the acetyl value was therefore abandoned, particularly as it did not seem likely to throw much light on the nature of the oil, and in any case the process would be too tedious to be of use in the ordinary analytical characterisation of the oil. The iodine value was determined, both on the nitrated oil and also on the fatty acids. The results varied slightly with different samples of nitrated oil. It was found that nitrated castor oil is best characterised by determining its nitrogen content by a modification of the Kjeldahl process. About 0.3 gm. of the oil was taken, and 30 c.c. of a mixture of equal parts of Nordhausen and ordinary sulphuric acid

was used. Potassium hydrogen sulphate was added to raise the temperature, and in the later stages oxidation was completed by the addition of a little potassium permanganate.

The analytical results on a number of samples of nitrated castor oil showed that the saponification value varied from 280 to 340. The iodine value was about 4 to 5, but one sample gave the figure 14.9. The iodine value of the fatty acids varied from 18.8 to 25.3. The nitrogen content varied between 2.3 and 3.8%, but was usually about 3%. The percentage of ash was less than 0.05%.

The foregoing analytical work throws some light on the constitution of the nitrated oil.

It is well known that castor oil consists practically of the pure triglyceride of ricinoleic acid. Ricinoleic acid contains one hydroxyl group and a double bond. When sulphuric acid acts on this acid the hydroxyl group is replaced by the sulphuric group and ricinoleo-sulphuric acid is produced. We should expect, by analogy, that when nitric acid acts on the glyceride of ricinoleic acid in the first place a nitric ester is produced, corresponding to the sulphuric ester produced with sulphuric acid. Failing this, the double bond is probably attacked, resulting in nitration of the type:—

In the former case the nitric group would easily be removed by hydrolysis, but in the latter case the nitro-group would probably not be thus eliminated. Experiment showed that the nitrogen in nitrated castor oil was entirely removed by hydrolysis. The fatty acids obtained from the saponified oil contained no nitrogen. This indicated that nitrated castor oil is the triglyceride of the nitric ester of ricinoleic acid. The hydrolysis of nitrated castor oil would therefore take place according to the equation:—

The saponification value of nitrated castor oil calculated from this equation is 301, a value which agrees with the approximate figures obtained.

To confirm this view of the constitution of nitrated castor oil, about five grams of the nitrated oil was saponified with alcoholic potash, and, after distilling off the alcohol, the soap was dissolved in water, decomposed with dilute sulphuric acid, and the product distilled in steam. The distillate was titrated with decinormal caustic soda, using methyl orange as indicator, and examined for nitric acid. Free nitric acid was found in the distillate, but the amount was very small, only 4.3 c.c. of N/10 alkali being required for its titration. It was evident, however, from the appearance of the distillation flask that considerable oxidation was taking place, and to this oxidising action of the nitric acid on its liberation the small amount in the distillate was probably due. The experiment, however, definitely proved that some nitric acid resulted from the saponification of nitrated castor oil, and this, with the fact that all the nitrogen is eliminated on saponification, affords strong presumptive evidence that nitrated castor oil consists largely of the glyceride of the nitric ester of ricinoleic acid. This experiment (which was quantitative) also showed the futility of any attempt to determine the acetyl value of the nitrated oil, due to the complex changes resulting when free nitric acid is liberated on acidifying the soap solution.

This view of the constitution of nitrated castor oil does not, however, meet all the facts. The iodine value of the nitrated oil should, on the above view, be very nearly the same as that of castor oil itself. As already stated, however, there is a decided drop. The iodine value fell from 84.4

(that of the castor oil used) to 14.9 at most, and usually to 4 to 5 units. These figures indicate that the double bond also has been attacked, and, since the foregoing work makes it unlikely that nitration takes place at this point, it is probable that oxidation has occurred at the double bond in the ricinoleic acid molecule. Various properties of the nitrated oil, particularly the dark colour of the solution of saponified oil and the appearance of the fatty acids obtained from it, led to the suspicion that the oil was an oxidised as well as a nitrated product. In the presence of ricinoleic acid, which is itself insoluble in petroleum spirit, it was difficult, however, to obtain evidence of the presence of oxidised acids other than that afforded by their colour. It was then found that acetylricinoleic acid is soluble in petroleum spirit, and this afforded a means of separating ricinoleic acid from any oxidised acids which would not acetylate or which gave acetyl derivatives insoluble in petroleum spirit.

The fatty acids obtained from nitrated castor oil were heated with acetic anhydride for some time, and the product, after removal of the excess of acetic anhydride, was extracted with petroleum spirit. It was only partly soluble, and the insoluble portion, which contained no nitrogen, had all the appearance and properties of complex oxidised fatty acids. This experiment afforded clear proof that oxidation of the ricinoleic acid takes place during the nitration to quite a considerable extent.

It appears therefore that nitrated castor oil is formed from castor oil as the result of the two simultaneous processes of nitration and oxidation. The nitrated oil will thus probably consist of the triglycerides of the nitric ester of oxidised ricinoleic acids. With this view its nitrogen content closely agrees. The pure triglyceride of the nitric ester of ricinoleic acid requires a nitrogen content of 3.7%, that of nitrated castor oil being about 3%.

DISCUSSION.

Mr. W. C. REYNOLDS stated that the fatty acids of castor oil formed a lactone when heated, and thought that the abnormal molecular weights found by the author in some of his results might perhaps be due to similar compounds.

Mr. WALTER F. REID was glad to hear that the subject was being investigated, because the nitro compounds of castor oil ought to be more extensively used in industry. Castor oil was not only an oil, but also partook of the nature of an alcohol. He did not think the author had really obtained true nitrated castor oil from his experiments. Nitration carried out with weak nitric acid was not complete; the acid used should be of sp. gr. 1.5. The presence of water caused oxidation and the formation of fatty acids. The nitrogen content should, he thought, be between 4 and 5%, certainly over 4%. The best factory test he had found for nitrated castor oil was the specific gravity. The author's figure of 1.05 agreed closely with figures he had found, although somewhat low, 1.127 being the average of several hundred determinations. He agreed that the presence of sulphuric acid was detrimental, the yield not being so good, nor the nitration so complete. He had nitrated many hundred tons in charges of from five to six hundred weights, of the oil and the temperature was controlled fairly well. During the operation the temperature rose rapidly until it reached a maximum and then fell again. This was necessary to a fully nitrated oil. He attributed it to the different components of the castor oil. There was also a solid form of nitrated castor oil. If highly nitrated oil were exposed to a temperature of 90° C. for a week it solidified, becoming like rubber, and would then amalgamate with rubber.

Mr. BRIGHTMAN replied that evidence of lactone formation would be obtained by determining the neutralisation and saponification values of the

fatty acids in the nitrated oil. Up to the present he had been unable to do this for lack of a suitable indicator, the dark colour of the oxidised acid over-masking the colour of the usual indicator. He did not think that the colour was due to the nitrous gases formed in the operation. The remarks of Mr. Reid confirmed the difficulties under which he had worked. He had no means of proving that the nitrated oil he had obtained was the same oil as that on which Mr. Reid and Dr. Lewkowitsch had worked. He had been surprised to find that dilute nitric acid nitrated fairly rapidly.

Meeting held at the Birkbeck Café on Monday, May 21st, 1917.

MR. R. F. HOWARD IN THE CHAIR.

THE UTILISATION OF CONDEMNED ARMY BOOTS.

BY M. C. LAMB.

In times of peace condemned Army boots were sold to contractors, who cleared all items of condemned clothing from the various barracks and camps. When war broke out and the Army grew rapidly, it was soon found that the standards of condemnation varied considerably, and an organisation was therefore set up to deal with old boots. By this means no boots are prematurely condemned, and all boots that are fit for further military wear are repaired for that purpose. The remaining boots are sorted into two grades, one of which is considered to be suitable for civilian wear after repair, and the other, although occasionally purchased by clog-makers, is generally speaking of no further use as footwear.

With an Army of such magnitude, although every step has been taken to secure economy in footwear, there must be an increasing quantity of boots unfit for further wear. The successful utilisation of this waste leather presents a very interesting problem. The Director of Army Contracts, who is responsible for the disposal of Army boots, has taken a great interest in this matter, and is of opinion that a solution can be found to the problem of discovering profitable utilisation.

The author has been permitted by the Director of Army Contracts to publish the results of the investigations of himself and others, including a special Committee of the British Association, in this field of operations, with a view to stimulating the interest of manufacturers in this waste material.

The average composition of this discarded footwear is as follows:—The total weight per pair varies from 3½ to 4 lb., consisting of approximately 11 oz. of leather uppers, and 45 oz. of sole, or say 20% uppers and 80% sole. The leather employed in the soling of Army boots is practically all vegetable tanned. The leather used in the manufacture of the uppers is of vegetable origin, to the extent of about 80% of the total quantity of boots contracted for, the remaining 20% being chrome tanned. The metal used in making of the boots is approximately 19% calculated on the total weight of the boot, and consists of 18.9% of iron, and 0.1% of brass; the latter is used chiefly in the eyelets.

Waste boot leather for road making. A promising way of utilising this waste leather is in the making of roads. In the early part of 1910, a patent was taken out by Mr. S. Brough, of Handsworth, for a road-making material which was subsequently known as "Broughite," in which scrap leather was incorporated with slag, granite, or limestone in conjunction with asphalt and bitumen. The claim made for this material was that a road was

obtained which possessed the hardness and rigidity of the ordinary tar macadam road, and at the same time reduced attrition and dust and was more resilient than the ordinary road, possessing an amount of "cushion" without liability of cracking on the surface.

The author was entrusted with the investigation into the merits of this method of road-making, and found that whilst all the reports which had been obtained upon the experimental roads which had been treated with this product, were of a laudatory character and in all cases where the experiment had been tried it had been found successful, no further progress had been made chiefly owing to the fact that the patentee had died. The Roads Board are now interesting themselves in this matter with a view to the use of leather from discarded Army boots as an ingredient in the process.

The quantity of leather used in compounding the macadam ranges from 5% when the roadway is to be subjected to very heavy traffic, to 10% when only light traffic has to be experienced. Assuming that the average amount of leather to be employed for the purpose is $7\frac{1}{2}\%$ of the road covering material, it will require 158 tons 8 cwt. per mile of roadway 8 yards wide. One ton of the tarred material is required for covering 6 square yards making an application 4 inches thick. Taking the average number of pairs of boots per ton at about 560 pairs, some 89,000 pairs of the worn-out product would be utilised in making each mile of the special roadway.

The method employed is simply to mix the scrap leather with the mixture of asphalt, bitumen, limestone, &c., lay the surface of the road with this composition, and afterwards give a top facing of slag, granite, or limestone.

Under the supervision of the Assistant Surveyor for Birmingham, Mr. H. H. Richardson, when District Surveyor for Handsworth, several pieces of roadway were laid. These experiments have indicated the advisability of the leather being in comparatively small pieces. The author has suggested that in the initial experiments now being carried out under the Roads Board the soles of the boots only should be used, a more profitable use for the uppers having been found. The soles should be cut into strips about one inch wide and the heels used intact, the strips from the soles being subsequently cross cut into pieces about 1 inch square. It is proposed, as above stated, to utilise the leather macadam mixture as a bottom dressing in making the roadway, as if used near the surface there is likely to be some difficulty owing to the fact that it would probably be too costly to remove the nails and the iron heel and toe plates before use.

The original experimental road made with "Broughite"—though laid as far back as 1910 and subsequently repaired with ordinary macadam, still retains to a considerable degree its original virtues of resilience and noiselessness under ordinary traffic conditions. It is a cheap and excellent substitute for wood paving, as in addition to possessing greater wearing qualities, and being equally silent, it costs much less than wood, and no more than bituminous macadam.

The experimental roadways provide excellent foothold for horses, as has been testified by the Officer Commanding the Military Riding School at Regent's Park Barracks; where an original Broughite roadway was laid in 1911; such a roadway also affords a good grip for rubber tyres.

Animal charcoal. Of the numerous investigations made by the author, the one which from the standpoint of commercial applicability is the most promising, is the use of the waste product in the manufacture of animal charcoal.

Animal charcoal is now almost exclusively

prepared from bones as a raw product, and is in considerable demand for use in the manufacture of munitions and as a decolorising agent for use in clarifying and decolorising sugar, oils and fats, gelatin, etc.

On submitting the leather to dry distillation the yield of crude charcoal obtained, in repeated experiments on a fairly large scale, was found to be in the neighbourhood of 35% of the total waste leather used. The resulting charcoal was boiled with dilute hydrochloric acid, treated with dilute caustic soda solution, and finally washed and dried, the result being a yield of comparatively pure charcoal equivalent in weight to about 25% of the total weight of leather distilled. The carbon so produced has been tested for its decolorising powers on sugar syrup and gelatin, with very satisfactory results; and the product, so far as could be ascertained from the small scale experiment, was in every way quite equal to any of the ordinary commercial products made from bones.

Ammonium sulphate. The distillation products were collected in sulphuric acid and resulted in a yield of 23%—25% of crude ammonium sulphate. The maximum amount available from leather is about 28% of the weight of material used.

Grease and fatty matters. On analysis the leather of the uppers was found to contain on an average 15% of extractable grease and fatty matter, consisting chiefly of wool stearine, cod oil, sulphonated oil, mineral oil, tallow, and paraffin wax. The fatty mixture as extracted from a number of representative samples of the leather was in the form of a moderately hard grease, of m. pt. 37°—39° C. This product was quite suitable for use in the currying of leather or for other purposes for which a low grade of grease is desired.

The present commercial price of charcoal prepared for decolorising purposes is in the neighbourhood of £40 per ton, crude ammonium sulphate for manurial purposes £16 per ton, and solid greases from £50 to £80 per ton. The value of the yield of products may therefore be taken as follows:—

1 Ton boots=560 pairs.	% lb.	Per ton.	Approx. value.
Metal.....	19.0=425	£ 5	£ s. d. 0 19 0
Grease and fatty matter (uppers).....	15.0=67	50	1 10 0
Purified charcoal.....	25.0=560	40	10 0 0
Crude ammonium sulphate.....	23.0=515	18	4 2 9
Total.....			£16 11 9

It would appear from the above figures that there is a good margin for profit in the employment of this raw material, which will be available in very large quantities, and as the process of conversion is very easy, requiring very simple apparatus, the matter should be of interest to practical charcoal burners and others, particularly in view of the fact that the raw material ordinarily employed is scarce in quantity, and not so commercially remunerative in the result; in addition, there is a considerable demand and extremely short supply of charcoal for commercial purposes at the present.

Manure. Leather waste is sometimes employed as a manure. The manurial value of leather, owing to its extremely slow decomposition, is small unless supplied in the form of dried or finely ground powder to the soil. It should be added that chrome leather, which will not decompose under ordinary conditions, is in consequence of no use as manure. It has also been noted that chrome tanned material is harmful to plant life.

Some of the specially compounded manurial products on the market possess a small quantity of leather as an ingredient, but this has usually been treated in some way to render it more suitable for the purpose.

The fusing of the waste leather with nitre cake after removal of the iron and brass rivets or eyelets, etc., was tried, fusing one part of the leather waste with two parts of the nitre cake. The result was a dry block of manure which could be easily powdered, and which on analysis gave the following results:—Ammonia 0.58% (equivalent to ammonium sulphate 2.2%). Total ammonia 1.8% (equivalent to ammonium sulphate 6.98%). This experiment was not very successful owing to the low manurial value of the resulting product, and the presence of large quantities of sodium salts.

Leather carbonised by aid of sulphuric acid is sometimes used as an ingredient in "patent" manures, and as the raw material now under discussion is cheaper than ordinary scrap leather, discarded Army boots might very well be used for this purpose.

Leather-board. The manufacture of leather-board has been the subject matter for a considerable number of patents, but as far as the author is aware, the manufacture of this article has not met with any considerable amount of commercial success, no doubt due to the fact that formerly the price of leather of inferior grade was not sufficiently high to enable leather-board to compete with it successfully. At the present time, the manufacture of leather board for use in insoles of boots, and soles of slippers, etc., employing this cheap discarded army footwear for the purpose of pulping, appears to be more attractive than in less strenuous times.

The following suggestions have also been made:

Clogs. Uppers of the old boots in a fair condition can be cut from the soles and nailed round wooden soles to make clogs.

Washers. The uppers of chrome tanned leather could be used for making washers for screw-down water taps. Experiment has shown that they possess considerable durability.

Mats. Waste leather can be used for making door-mats on the principle of chain belting.

Leather-pulp. Pulping the leather for leather board or paper is probably practicable but its competitor for this purpose would be the quantity of waste scraps, cuttings, and machine turnings of new leather which is more suitable to work up. The relative prices of the two materials would decide whether this would be a sound commercial proposition.

Leather powder. Leather powder for case-hardening could be obtained from vegetable tanned leather by treatment with wet steam.

Cyanides. The possibility of making cyanides has been discussed.

Glue and size. Glue of an inferior quality could be made, the chief difficulty lying in the presence of an admixture of chrome and vegetable tanned leathers. It is possible to separate these by treatment with wet steam, and there are two processes, one of which is already patented, for obtaining glue material from chrome leather. One of these consists in treatment with sodium peroxide, and the other treatment with a solution of Rochelle salt or a salt of some other hydroxy-acid. At present, the price of tartrates is a serious consideration, but they can be recovered almost quantitatively in the process.

The author desires to express his indebtedness to Mr. A. Harvey for his assistance in carrying out many experiments, and to Mr. A. Bradley for his kindness in making several tests of the prepared charcoal in decolorising sugar syrups.

DISCUSSION.

Mr. ROBERT STEWART said that many years ago—so far back as the early eighties—he had used several hundreds of tons per annum of leather waste in the manufacture of prussiate of potash by the old pot process. The works in which he had been interested was situated in Leeds, where,

at one time, the prussiate industry had been one of some magnitude. The locality was a particularly favourable one for the prussiate manufacture, inasmuch as there was always a plentiful supply of "animal matter" from the woollen mills in the neighbourhood, and leather waste from the tanneries and boot factories; there had been also a ready market for the finished prussiate, as it had been in those days extensively used in Yorkshire dye houses. There had been two or three good-sized prussiate factories at Manchester, but the most important one of all was just outside Glasgow, owned by the Hurlet and Campsie Alum Company. The trade had been heavily hit by German competition, although there had always been a decided preference in favour of English or Scotch prussiate, but the *coup de grâce* had been given to the industry by the growing use of aniline dyes and the continual development of methods for the obtaining of prussiate of potash and soda from gas residuals. Doubtless there would later on have been a partial resuscitation of the defunct pot process to meet the demand for cyanide for gold extraction but for the discovery of more direct methods of producing cyanides. There was a considerable amount of "prussiate char" produced as a by-product, but, at the time of which he spoke, it had been difficult to get more than a few shillings per ton for it. Some few years after the closing down of the last prussiate works in the United Kingdom, this char had been worth £20 per ton, several important applications, such as the bleaching of ozokerite and paraffin wax, having been found for it. To-day, as Mr. Lamb had mentioned, its value would be about £140 per ton. "Prussiate char," after having been freed from certain impurities, was said to have ten to twenty times the decolorising power of other forms of animal charcoal. He was under the impression that some of the decolorising charcoal met with in trade, and which he believed came from Germany, was actually made by the prussiate process, the ferrocyanide in this case being the by-product. Mr. Lamb had made some reference to the production of cyanogen compounds being one possible way of utilising leather waste, and he thought this suggestion was deserving of consideration in view of the present value of animal char. Except for the latter circumstance the fusion process of manufacturing prussiate of potash could not possibly compete with modern methods, such as the fixation of atmospheric nitrogen, and of course, unless or until potash was once more obtainable at something like pre-war prices it could not stand at all, even with animal char at £140 per ton. Given potash at £15 to £20 per ton, however, there was no doubt that the old pot or fusion process would be profitable. Much of the leather waste dealt with in Mr. Lamb's paper would consist of "uppers." Now whilst sole leather parings gave a very fair yield of prussiate the waste from upper leather gave very poor results. That was found to be due to the quantity of grease it contained, although why the actual nitrogen content was not recovered in the finished product had not been solved. The upper-leather waste was, therefore, first boiled to extract the grease, which on cooling rose to the top of the vat; the boiled leather was submitted to hydraulic pressure to squeeze out the adhering grease; the pressed cake on cooling became quite friable, in which condition it could be very easily ground in an ordinary disintegrator to a very fine powder which might be applied as a fertiliser. The pressed cakes were quite as valuable as the sole-leather for prussiate making. The grease obtained, amounting to 18–20% of the weight of the original leather, found an application in currying and soap making. The prejudicial effect of grease on the yield of cyanogen was very marked in all kinds of animal matter—such as woollen—used in prus-

prussiate making. It was a well-established fact that animal charcoal produced in contact with fused alkalis possessed a higher value as a decoloriser than the char obtained by the destructive distillation of animal matter *per se*, but he was not aware whether soda was as effective as potash. This was a matter well worth investigation, for, obviously, it would be far simpler to install a plant for producing animal char by the fusion of sodium carbonate and leather waste, than to rehabilitate the now obsolete pot process of manufacturing prussiate of potash. One process for utilising leather waste mentioned by Mr. Lamb consisted in treating the waste with sulphuric acid; this recalled some work he (the speaker) had been

however, always becomes intensely blue with the addition of the first drop of thiosulphate solution. The introduction of starch solution before the alkaloid is important, because if free iodine is liberated it reacts with the alkaloid, forming an iodo-compound which often vitiates the results. To study the effect of time and to ascertain what excess of iodic acid is required, the following experiments have been carried out. The solutions were placed in 500 c.c. Erlenmeyer flasks, set aside in a cool, dark place for stated periods, and titrated with *N*/10 thiosulphate solution to determine the amounts of unchanged iodic acid. It has been found that the oxidation of morphine is not complete in less than 10 minutes; the

Time.	15 min.	15 min.	15 min.	30 min.	60 min.	120 min.
Water	50 c.c.	50 c.c.	50 c.c.	50 c.c.	50 c.c.	50 c.c.
10-N sulphuric acid	5 "	5 "	5 "	5 "	5 "	5 "
1% starch solution	10 "	10 "	10 "	10 "	10 "	10 "

engaged in eight or ten years ago. Leather waste was macerated in strong sulphuric acid whereby it was quickly reduced to a pulpy mass; the strongly acid mass was mixed with ground mineral phosphate, the aim being to produce a nitrogenous superphosphate. The patent, however, had never got beyond the provisional stage as it was found that the finished product contained much less nitrogen than the quantity calculated from the nitrogen content of the leather used.

Communication.

TITRATION AND ESTIMATION OF MORPHINE WITH IODIC ACID.

BY JITENDRA NATH RAKSHIT
(Opium Factory, Ghazipur, India).

The liberation of iodine from iodic acid by morphine was observed by Serullas (Berz. Jahresh., 11, 238) and Dupré (Jahr., 1863, 704). A colorimetric method for the estimation of morphine by extraction of the liberated iodine by means of chloroform or carbon bisulphide was proposed by Procter and Stein (Jahr., 1871, 957); this method, however, has been found to be unsatisfactory. François and Luce (Ann. Falsif., 1916, 9, 83; this J., 1916, 315) have also described a colorimetric method for the estimation of morphine by means of iodic acid and ammonia, but the following titration process seems to be more reliable. If a solution of morphine be treated with an excess of iodic acid in the presence of dilute sulphuric acid, the oxidation of morphine is quantitative, two molecules of morphine absorbing three atoms of oxygen. $2C_{17}H_{19}NO_3 + 3O = (C_{17}H_{19}NO_3)_2O_3$. But the reduction of iodic acid in the presence of an excess of morphine is incomplete the degree of reduction depending much on dilution, temperature, and time.

The solution of iodic acid suitable for this purpose was prepared by dissolving 5.86 grms. in 1000 c.c. of water (equivalent to *N*/5 thiosulphate solution); it keeps well for a few months without altering its titration value. When about 1% solution of morphine is treated with an excess of iodic acid solution, the colour of the mixture changes to brown but the starch solution does not generally become blue. Experiments in which the starch solution is blue show little difference in titration from those in which there is no action on starch. The starch,

above results show that it does not proceed much further even after as long as two hours. Numerous experiments have been carried out and it has always been found that 15 minutes is quite sufficient to complete the reaction. In the estimation of morphine by this process it is convenient to use about 0.05 to 0.15 gm. of morphine (either in the form of free base, hydrochloride, or suphate), 50 c.c. of water, 5 c.c. of 10-N sulphuric acid, and 10 c.c. of 1% freshly prepared cooled starch solution, and shake well; 5 to 15 c.c. of *N*/5 iodic acid solution is then introduced, the mixture shaken again thoroughly, set aside in a dark place for about 15 minutes, and titrated back with *N*/10 thiosulphate. The number of c.c. of iodic acid consumed multiplied by 0.0190 gives the amount of morphine present in the quantity of sample taken. Satisfactory results are, however, obtained by using double the quantity of iodic acid solution that is required for oxidation. The following results have been obtained with pure morphine :—

Morphine taken.	N/5 Iodic acid required.	Morphine found.
gm.		gm.
0.100	5.15 c.c.	0.0979
0.120	6.20 c.c.	0.1197
0.080	4.25 c.c.	0.0807
0.090	4.75 c.c.	0.0902
0.150	7.99 c.c.	0.1501

While titrating it is essential to note that the end point should be taken when the blue colour has remained discharged for at least 30 seconds; the colour, however, often reappears after a few minutes and can be discharged with a drop or two of thiosulphate solution, but the same colour may return after a longer time.

It was thought that this reaction might be used for the estimation of morphine in opium, but it has been found that the results obtained are too high and are always discordant owing to the fact that codeine and narcotine also absorb a certain amount of oxygen under the same conditions, as is shown below :—

Sample.	N/5 Iodic acid reduced.	Equivalent quantity of morphine.
		gm.
0.100 gm. codeine, ...	1.0 c.c.	0.0190
0.100 gm. narcotine	0.25 c.c.	0.00475

Besides these alkaloids there are also other substances in opium which absorb oxygen under the same conditions.

Industrial Notes.

FIFTY-THIRD ANNUAL REPORT ON ALKALI, ETC., WORKS, BY THE CHIEF INSPECTOR, 1916.

The number of registered works in England, Ireland, and Wales was 1393 in 1916, compared with 1372 in 1915 and 1356 in 1914. There were also 167 works in Scotland registered under the Act, making a total of 1560. The amounts of acid gases escaping in the processes under inspection showed various differences but were generally higher than in 1915; the acidity of gases from chimneys in smelting works showed, however, a slight decrease.

Alkali and copper (wet process) works. The average escape of hydrochloric acid from the chimneys in these works was 0.086 gr. per cub. ft., compared with 0.074 gr. for 1915, the average condensation being 97.9%, compared with 98.31% in the preceding year. As in 1915, the use of nitre cake in place of sulphuric acid for decomposing salt in salt-cake furnaces lessened the production of acid made per ton of salt-cake produced. In certain localities also the furnaces were not worked to their full capacity. During the year a modern mechanical salt-cake furnace of the muffle type was introduced in one district, and after preliminary troubles, especially with the mechanical feed, had been overcome, fairly good results were obtained, though the amount of acid produced was only about 75% of the anticipated capacity of the plant. The use of mechanical furnaces in the larger works for the extraction of copper by the wet process has become general.

Smelting works. The average acidity of chimney gases from these works decreased from 3.056 grs. SO_2 per cub. ft. in 1915 to 3.010 grs. in 1916; the number of works was four less than in 1915, two works relinquishing smelting operations to work up material for munition purposes. The acidity of escaping chimney gases from works engaged in tin smelting and arsenic recovery was maintained at about the same as in 1915, through the continued use of limestone or milk-of-lime in suitable washing towers. Considerable activity in mining for wolframite in Cornwall is reported, and it is mentioned that the present tungsten production of the Cornish mines is more than three times that of the German and Austrian mines. In works in which zinc sulphide ores are calcined further progress was made in the utilisation of the sulphur for producing sulphuric acid, in spite of difficulties connected with the working of mechanical calcining furnaces and the scarcity of suitable labour for working the necessary hand furnaces. No great extension was seen in the application of electrical and mechanical means for arresting fume and dust.

Cement works were seven less in number than in 1915. Many works also were only partially in operation. The question of the recovery of potash from dust continues to receive attention, but no reports have been received of any practical trials having been made.

Sulphuric acid works. The average escape of gases from the lead chamber process was 1.269 gr. per cubic foot in 1916, an increase of 0.132 gr. over 1915; the majority of works, however, showed no increase in this respect. A high standard of proficiency was maintained in most of the works; in many of those where former

standards were not reached, it is noted that proper chemical aid was not at hand. The demand for acid, combined with difficulties regarding skilled labour and supplies, was more marked than in 1915. Constructive effort was actively maintained, so that at the end of the year the general conditions were better than at the end of 1915. An experiment was made at a Swansea works in washing down the coke in a Gay-Lussac tower with acid and then with water; the washing was continued for four days, until the wash-water was practically free from acid. The nitrous fumes evolved in the washing with water were led to the Glover tower of another set of chambers, whereby potting was saved for two days and the acidity of the exit fell to 0.50 gr. SO_2 per cub. ft. The washing resulted in the coke readily rolling out in loose pieces, thus avoiding the breaking up process necessary after long service in a coke-packed Gay-Lussac tower. Washing for 96 hours may not be necessary in every case, and when the nitrous gases can be readily utilised the preliminary wash with strong acid may be omitted.

Mechanically worked furnaces for calcining sulphide ores of zinc are still in the introductory stage, and mechanical furnaces for roasting pyrites and spent oxide came into more extended use.

There was considerable reduction in the chamber space allowed per unit of sulphur burned. Other aids to increased and efficient production were the use of large Gay-Lussac towers or other absorbing plant, fan draught, water sprays, externally cooled chambers, increased burner capacity, increased nitre consumption, and closer attention to all details of working. A suggestion of the Chief Inspector which is being introduced into two works is the provision of an iron contact tower between the burners and the Glover tower; this would effect a material conversion of the SO_2 to SO_3 . By erecting a second set of burners and iron contact tower, a further quantity of gases would be produced, and by passing both these quantities of gases through the Glover tower, a product would result containing little more sulphur dioxide for the chamber set to deal with than was formerly derived from one set of burners.

Sulphuric acid (Class II.) works. Contact processes. A large increase in the operation of contact plants is reported, both as regards extension of existing works and erection of new ones. Production was considerably increased, and further increase is in prospect. In using the iron oxide contact process in conjunction with chamber plant, trouble arose from the sluggish action in the chamber of the gases from the contact section. This was obviated later by the judicious use of steam, proper mixing with the chamber gases, and selection of the most suitable point in the chamber system for their admission. Extensive operations were carried on satisfactorily with the "Mannheim," the "Badische," and the Tenteleff processes, whilst during the year the Schröder-Grillo process was successfully introduced. *Concentration processes.* The average escape of acid gases showed an increase of nearly 25% over that of 1915. In addition to emission of unduly acid residual gases from flues and chimneys, there was much irregular escape from the plants themselves. In cascade concentrating plant, high acidity of exit gases may be due to excessive boiling in the lower basins (resulting in acid being projected into the flues), to insufficient size of scrubbers for the exit gases, and to insufficient draught in the basin flue. In other types of concentrating plant there was less opportunity for irregular escape of acid. In some cases also where spent acid containing nitrogen compounds was being recovered, an undue escape of nitrogen oxides occurred. Reference is made to the satis.

factory use of the Davis concentrator for concentrating acid from 110° Tw. to 144° Tw. The Thomas-Harris plant for making high strength acid is not yet a regular producer in quantity. Two new methods of treating the fume developed in concentrating plants have given satisfactory results in trials; one method consists in causing the particles to coalesce by means of high-tension electrical discharges; in the other method, water or weak acid is supplied to the fan used to induce draught on the fume fine of cascade units.

Chemical manure works. The number of works continues to decrease, two less being registered in 1916 than in 1915. The reduced supply of sulphuric acid was met to a limited extent by the use of nitre cake; this has proved satisfactory in some cases, a product with 17—20% soluble being obtained. Imports of certain fertiliser materials into the United Kingdom were as follows:—

	1914.	1915.	1916.
	Tons.	Tons.	Tons.
Guanos	34,285	26,720	21,644
Mineral phosphates	555,695	374,839	333,371
Sodium nitrate	171,910	132,158	20,896

Exports of sulphate of ammonia in 1916 amounted to 259,500 tons, compared with an estimated home consumption of 178,500 tons; the corresponding figures for 1915 were 294,000 and 128,000 tons respectively.

Sulphate and muriate of ammonia and gas liquor works. The number of works in this group continues to increase. The quantity of ammonia recovered as a by-product in the United Kingdom was:—

Ammonia recovered (as sulphate); tons.

	1914.	1915.	1916.
Gas works	175,930	173,675	172,269
Iron works	16,098	15,142	15,154
Shale works	62,749	54,826	57,988
Coke-oven works	137,430	145,496	159,596
Producer-gas and carbonising works (bone and coal)	34,205	33,218	28,786
Total	423,412	428,267	433,703

Of the total for 1916, 70,987 tons was produced in the form of concentrated ammoniacal liquor. The change from production of sulphate to the preparation of concentrated ammoniacal liquor continued in greater measure during the year under review. The use of a cheap oil, crude tar, etc., for facilitating the removal of those metallic sulphides precipitated in the saturator when crude pyrites acid is used for producing sulphate from gas liquor, is now in limited use in England; it has been in general use in Scotland for a long time. The "direct process" for the manufacture of sulphate of ammonia has been further investigated and some experiments have also been carried out on the sulphiding of hydrated oxide (see page 997).

Nitric acid works. Increased activity continued in these works, new plants being erected and large additions made to existing works. Increased condensing appliances were provided where more intensive working called for their use. In some localities there was still a surplus of nitre cake.

Muriatic acid works. The results of the limited inspection which these works received indicated that they were conducted without undue escape of noxious gases. The salt works, carbonising works, and works making hydrochloric acid were conducted without change in methods. A development in tinplate manufacture which dispenses with the necessity for "white pickling" is mentioned.

Sulphide works. An increase from 92 to 96 in the number of works registered in this class is noted, chiefly due to the extended manufacture of certain dyes. In the works in which metallic impurities were removed from acids by means of sulphuretted hydrogen, or works in which anti-mony sulphides were manufactured, the waste sulphuretted hydrogen was satisfactorily disposed of.

Arsenic works. In those works in which arsenious acid is obtained from arsenical ores or residues, or in which arsenious acid is refined, dry filters continued to prove more satisfactory than wash towers for treating the escaping gases, though in both types the final escape was satisfactory.

Picric acid works. The number of works increased from 13 in 1915 to 18 in 1916, all the new factories being of important productive capacity; large extensions were carried out in existing factories. The treatment of waste fumes leaves much to be desired, although advance has been made in some factories. Improved methods of reducing working losses of picric acid and for the recovery of waste acid have been introduced.

Tar works. An increase of 68, to 316 works registered, is recorded, almost entirely due to the rapid extension of the use of tar dehydrating plants in gas works. Continuous distillation plant was largely adopted, but in some cases these were not provided with sufficient condensing arrangements; apart from temporary escape of vapours due to this cause, the tar works were conducted satisfactorily as regards the requirements of the Act. The quantity of tar distilled in the United Kingdom in 1916 was 1,420,867 tons in gas works and 138,552 tons in other works; 715,051 tons of pitch was produced in gas works and 83,690 tons in other works.

Zinc works. Extensive additions were made to registered works, but no new works were added. No progress is reported in the treatment of fumes from zinc furnaces.

SCOTLAND.

The following statistics have been compiled:—

	1916.	1915.
Pyrites burned	Tons. 152,084	Tons. 144,946
Bones and phosphates dissolved	36,686	64,892
Salts of ammonia (expressed as sulphate)—		
Gas works	Tons. 21,365	
Iron works	14,310	
Shale works	57,988	
Bone, producer gas, coke, and carbonising works	21,030	
Tar distilled—		
Gas and coke oven works	139,197	
Other works	126,285	
Pitch produced—		
Gas and coke oven works	70,879	
Other works	75,274	
	146,153	143,011

Of the above total quantity of sulphate of ammonia the equivalent of 7246 tons was manufactured as concentrated ammoniacal liquor; the balance of 197,447 tons consisted of other ammonia products (sulphate, chloride, nitrate, etc.).

In sulphuric acid works, sulphuric acid (Class II.) works, and in zinc works, great activity prevailed, whilst in chemical manure works operations were greatly restricted owing to the moderate supply of sulphuric acid available.

Alkali works were conducted satisfactorily during the year, no discharge of chimney gases containing muriatic acid in excess of Act limits having been observed. The extended use of mechanical furnaces further lessened the danger

of local escapes of acid gases. At one works some local heating of the adjacent deposit of alkali waste, due to oxidation, was noted.

Sulphuric acid. At three works escapes of acid gases in excess of the limit fixed by statute were noted, and in addition escapes of acid gases occurred through leakages in the manufacturing plant. Additional plant was under construction, but none was completed at the end of the year.

Sulphuric acid (Class II.) works. Contact process works.—This description of works was satisfactorily conducted throughout the year. One new works was started towards the end of the year, and extensions were brought into use in works already registered. *Concentration process works.*—The pressure on these works was heavy and continuous. Plants of three types were in use—the Kessler, the Gaillard, and the cascade. The first two were worked satisfactorily, but the third gave cause for criticism as regards escape of noxious fumes otherwise than by the chimney. Imperfect distribution of heat over the system, with pressing of the plant for a large production combined to effect rapid deterioration of structure, and were largely responsible for the less satisfactory conditions in some of these plants.

Chemical manure works. In one works a new mechanical mixer was operated with satisfactory results alike as to production and to the working conditions inside the works. Conditions generally were good; the discharge of acid gases was low.

Sulphate and muriate of ammonia and gas liquor works. The liquor distilled from gas works was equivalent to 21,365 tons of ammonium sulphate, and the noxious gases were destroyed as follows:—In oxide of iron purifiers, 72%; by combustion, 16%; by Claus process, 11%; and by precipitation by metallic salts, 1%. At one work the stock of oxide was renewed after 14 years' continuous service; during this long period it largely increased in bulk and value. It was necessary to use exceptional means to maintain its vigour. Plans are in progress for conversion of several large sulphate of ammonia units to the production of concentrated ammoniacal liquor.

Zinc works. Associated with increased production of zinc there was a large increase in the calcination of sulphide ores. The use of prolongs to arrest the fume leaving the receivers for condensed zinc vapour was extended and improved, but difficulties were met with in ensuring their proper utilisation. The solid matter obtained by the condensation of fume in these prolongs is of high market value.

DEVELOPMENT OF THE AMERICAN DYESTUFFS INDUSTRY.

U.S. Comm. Rept., Aug. 15, 1917.

An examination of returns made to the Bureau of Foreign and Domestic Commerce by practically the whole dyestuffs industry in the United States indicates an increasing tendency to amalgamation of interests among certain plants making crudes and intermediates with others producing finished dyestuffs, which will probably result in the output of a greater variety of colours at a decreased cost of production. As far as actual figures are available, the total amount of capital invested in the industry in the United States would appear to be 163,025,650 dols. This amount does not include capital invested in dyestuffs production by ten firms, some of which are just beginning operations, while others are not incorporated and have no capital stock, but are amply financed or are owned by a single individual. These plants will probably be in full operation by 1918, and several million dollars of capital will thus be added to the

industry. From figures submitted by manufacturers, the following totals of monthly production for the current year have been compiled:—Twenty-two firms manufacturing crudes report a monthly output of 1,240,350 gallons of benzol, toluol, and some xylol and phenol, and 6,181,600 lb. of benzol, toluol, natural and synthetic phenol, cresol, naphthalene, anthracene, and some xylol, cumol, and anylene; forty firms report a monthly output of 10,120,600 lb. of intermediates; forty-six firms had an output of 5,000,000 lb. of artificial colours per month; and thirteen firms an output per month of 8,183,500 lb. of vegetable dyestuffs and extracts (including some tanning extracts not stated separately). For general purposes, it is said, these figures may be taken as fairly representative of the industry as a whole. The major portion of the total output of intermediates in the United States is probably consumed in the dyestuffs industry itself, although a large amount, especially trinitrotoluol, falls in the category of explosives. There is a constant increase in the variety of intermediates and chemicals produced in the United States for making colours. Dyestuffs manufacturers are now producing large quantities of toluidines, resorcinol, xylidine, dianisidine, naphthylamine, diphenylamine, tolidine, benzidine, benzaldehyde, benzyl chloride, nitrobenzol, nitrotoluol, 11-acid, phthalic, metanilic, sulphanilic, and naphthionic acids, naphthol-sulphonic acids, naphthylaminesulphonic acids, and aminonaphtholsulphonic acids, Schaeffer's salt, paraitraniline, dimethylaniline, and numerous others. A glacial acetic acid plant of large capacity is expected to begin operation immediately.

Coal-tar dyes in a variety of colours are now regularly obtainable from domestic sources. Several manufacturers carry full lines of direct, acid, basic, chrome, oil, and sulphur colours; while others confine their efforts to improving and extending their output of particular groups. Prominent among the colours produced are, nigrosines, indulines, triphenylmethane dyes, safranines, eosins, chrysoidines, rhodamines, rosanilines, direct fast reds, browns, and yellows for cotton, fast chrome colours for wool, Sudan colours, basic violets, synthetic indigo and indigotins, alkali blues for the silk and woollen industries and also for the lithographic trade, metanil yellow, methyl violet, methylene blue, benzopurpurine, benzo sky blue, primuline, naphthol green, rose benzale, gallo-cyanine and special chrome and khaki colours. Considerable attention is being given by about a dozen firms to developing as rapidly as the requisite intermediates are available, the triphenylmethane dyes, particularly fuchsin, methyl violet, methylene blue, magenta, and malachite green. The itemised figures given by only a few of the plants show a monthly production of this series of colours amounting to 62,200 lb. Of this quantity 18,200 lb. represents methyl violet and 13,450 lb. methylene blue. Two manufacturers specialise on intermediates for these dyes. There is a largely increased production and variety of reds, yellows, and scarlets. A wide range of fast reds, blues, greens, yellows, blacks, and greys for cotton is also available. Colours now produced on a commercial scale that were not made in the United States until recently are alizarin blues, browns, and yellows for calico printing, and for wool; para colours for lakes or pigments, vat dyes (indigoids) for cotton shirtings and gingham, synthetic indigo, rhodamine, patent blue, and Biebrich scarlet.

Present production and new developments contemplated also include blacks and greens in natural dyes for calico printers, a special logwood blue, special mordants for dyeing new shades in direct cotton colours, khaki dyes, cutch, archil, and logwood extracts, and powdered eudbear, orange and lemon flavines, Osage orange in a variety of shades,

American sumac extract, indigotin, and natural indigo shades. It is stated by several plants that their output depends on the domestic demand, ample facilities being available for a largely increased production at any time. Some plants operate at half capacity, while others are running 24 hours a day. One firm is making sulphur brown (not a coal-tar product) on an extensive scale, while another company is producing mineral colours in standard shades for wool. Soluble Prussian blue, Chinese blue, pigment brown, lakes in all the principal colours, para-toners, dry colours, and dyes for lake makers are handled by different manufacturers.

Announcement has been received of the entrance into the dyestuffs industry of the leading American company manufacturing explosives. Other new plants in process of construction or to begin operations before 1918 are two for coal-tar crudes, one for anthracene, one for glacial acetic acid, four new buildings for aniline dyes, one for chrysoidine and methylene blue, one for nigrosine, induline, and magenta, and one for nigrosine only. A producer of direct, acid, and chrome colours expects to double his present output of nearly 500,000 lb, annually during the next twelve months. One plant making methylene dyes is planning to double its capacity, two others making aniline colours will also double their capacity shortly, one manufacturer expected to have patent blue and fuchsin on the market after July, one of the larger corporations is now making auramine and lanafuchsin on a small scale and installing equipment for their increased output, and another contemplates the manufacture of primuline in considerable quantity. A producer of high-grade colours for silk is enlarging his factory and contemplates the early production of safranine, and the installation of a suitable plant for the extensive manufacture of aniline dyes. Experimental research is in progress on a great variety of products that are now being manufactured on a semi-commercial scale with a view to increasing production as the processes are worked out in different establishments.

Dyes and dyestuffs exported from the United States during the fiscal year ending 30th June, 1917, were valued at 11,719,887 dols., as compared with 5,102,002 dols. in 1916.

GERMAN CHEMICAL INDUSTRIES.

The "Neue Zürcher Zeitung" recently published a review of German activities in technical matters in the field of war economies, in which it is stated that systematic investigations into the properties of pit coal have been carried on by the "Kaiser Wilhelm Institut für Kohlenforschung," and have yielded important industrial results. The treatment of coal with liquid sulphurous acid at ordinary temperatures has produced viscous, golden-yellow mineral oils, the amount produced being 5 kilos. per metric ton (see this J., 1916, 1001). A process has also been elaborated by which through heating naphthalene under pressure, in the presence of aluminium chloride, an oil is produced which can be used for illuminating purposes in the same manner as petroleum (this J., 1913, 350). Finally, by treating with ozone, it has been found possible to alter the carbon compounds in coal to compounds soluble in water, the chemical importance of which cannot at present be estimated (this J., 1916, 1001).

The utilisation of lignite has been greatly extended. In the first place it is being used extensively as a fuel in the industrial establishments which have recently sprung up in the

Central German lignite fields, especially in the neighbourhood of Bitterfeld and Halle a/S, where the German air-nitrate factories are situated. A process has been discovered by which nearly twice the usual amount of ozokerite can be obtained from lignite, and the gas is being more extensively used for heating and smelting purposes.

In the production of nitrates directly from air a new process has been discovered, which works with quadruple air velocity through the reaction space and produces a result about 80% higher than could be obtained before.

In the metal industry further progress has been made with the production of substitutes for copper, brass, and bronze, especial mention being made of the different zinc and lead alloys, and of the increasing importance of aluminium. Recently there have been new developments in ore smelting. With copper schists the metallurgical possibility of going as low as 0.7% has been shown, whereas formerly the average lower limit was 2.5%. Operations have been commenced upon large deposits of sandstone containing lead. Successful experiments have been made in obtaining aluminium from clay, which will, it is claimed, make Germany independent of foreign bauxite in future. With nickel ores the workable limit has been reduced from 2.5 to 1.5%. A process has also been discovered for obtaining nickel and cobalt from mine waters containing these substances.

In the German rubber industry the situation is said to have been eased by the progress made in rubber regeneration, and by the substitution of mechanical spring wheels for pneumatic tyres. The idea of exploiting German caoutchouc plants has been given up.

Nettles have become more and more important as a source of fibre. The uses to which paper textiles are put are also constantly increasing, and qualities are being produced which are durable and will even stand washing. (*Board of Trade Journal* Sept. 13th.)

Correspondence.

CENTRAL SCHOOL OF ANALYTICAL CHEMISTRY.

SIR,

I have now been engaged in technical chemistry for over a year, and I have been struck pretty forcibly by the fact that a firm's analytical routine is apt to go on along the same lines for long periods of time. If, on the other hand, it is realised that some long-established method is by no means perfect, and reference is made to the Section on Analytical Chemistry in the Annual Reports of the Chemical Society, the number and diversity of new methods cited is bewildering, and hope of replacing an old and slow method by a new and rapid one is reduced by the great number of such new methods, trial of and selection from which might well take months. Learning new methods from books alone is never entirely satisfactory, and there is at present great need of a living contact between the pioneers of chemistry and those who might benefit by their work.

It is an established custom to hold Post Graduate courses for doctors. I write to suggest that something of this sort might be arranged for analytical chemists as well. Men and women busy all day in routine analytical work are unlikely to avail themselves of new methods; indeed the attempt to do so would much upset their routine on which the efficient running of factories so much depends.

What is wanted is a Central School of Analytical Chemistry to which analytical chemists could be sent occasionally by their firms for a short time, and where they could learn new and quicker methods, or improvements in old ones. The nett time such a scheme would save the country would soon be enormous. Such is the crude idea, and, of course, it requires a great deal of hewing into shape, and this cannot be done till after much discussion.

As an imaginary forecast of the Central School of Analytical Chemistry and its manner of working I venture to put forward the following. Let us suppose the School in existence, housed in such a building as that containing the Laboratory of the Institute of Chemistry; and let us also suppose that the management of a firm are painfully aware that one of their analytical methods is unsatisfactory. The management will then write to the Director of the School stating their difficulty, and asking if better methods exist. If the Director of the School can help it will be arranged that the firm's chemist shall attend the school for a time sufficient to gain complete mastery of the new process. I think that during this time the chemist should still be paid his usual salary by the firm, who should also pay the school fees. The firm should, however, be entitled to a refund of the fees from their employee if the latter leaves them before the new process which he has learnt is firmly established in their laboratory. I am against the chemist attending the school either in the evenings or during his usual holidays. It is only men of exceptional physique who can thus afford to work over their normal limits with advantage either to themselves or to those for whom they work.

The question of the upkeep of such a school is a difficult one, whether it should be run by the State or jointly by manufacturers to whom it is likely to be of service. But in any case movements of both sorts are in the air at the present time, and I put forward the above ideas as being, after all, only a particular case of what I am thankful to say is now a general tendency.

I am, etc.,

R. C. MENZIES.

Loughton, Essex.

September 27th, 1917.

LOW TEMPERATURE DISTILLATION OF INFERIOR COALS.

SIR,

In reading the interesting article by Mr. T. F. Winnill in the August 31st issue of the Journal, my attention is drawn to the point that the distillation of the coal was carried out under a vacuum of 26 inches to 28 inches of mercury. If the plant mentioned is merely an experimental one erected for academic purposes, this fact may pass, but if the carbonisation be carried out in future on a commercial scale, it appears to me that working under such an approximate vacuum as that mentioned in the article, would involve a collision with the patents held by the "Tarless Fuel Syndicate," which cover carbonisation of coal at low temperatures under vacuum, and I have no doubt that the proprietors of the patents would exert every effort through the proper legal channels to uphold their proprietary rights.

As far as using in the retort a "stirrer" or even a continuous screw or helix, it is curious how this idea has fascinated carbonizers, especially of the

amateur or patent-seeking type, for almost a generation past, and the records of the Patent Office bear testimony to this.

Quite recently I had in a foreign country the opportunity to work practically an installation of this type, erected at some considerable cost, and on quite a substantial scale. It was erected to deal with the easiest of coals to work, viz., a poor lignite, of course non-caking. It failed hopelessly, as it churned the lignite to breeze (some 30% to 40%), and failed to produce a reasonable amount of tar oils. The installation is to be displaced in favour of a more modern and perfected system which is now being effected, as the trials of the lignite sent to this country to be tested by the process indicated proved very successful, yielding—

Petrol	2.2 gallons per ton.
Light oils	4.4
Heavy oils	6.95
Sulphate	22 lb.
Good smokeless fuel ..	12 cwt.

My experience goes further; with screw retorts, working rich bituminous coals or cannel, there is the greatest mechanical difficulty in getting the screw to pass such coals or cannel, as when they get to the sticky stage, the power required to operate the screw is enormous.

Yours faithfully,

F. D. MARSHALL.

Past President, Institute of Gas Engineers.

19, Queen Anne's Chambers, S.W.,

September 12th, 1917.

Obituary.

CLAYTON BEADLE.

Clayton Beadle, who died on August 16th last, was born in 1868, and was educated at Dover College. After a short time spent in studying the routine of paper-making, he entered the laboratory of Cross and Bevan in 1886, and later became a partner in the firm. Whilst there he was engaged in investigations in connection with cellulose, and especially in regard to the work which led up to the foundation of the viscose industry. On the lapse of his term of partnership he joined with others in forming the British Viscoid Company, which launched an experimental works at Erith under his management. He was also actively interested in the work of the Viscose Syndicate and the Viscose Development Co. For many years he has been engaged in consulting practice, in partnership with Dr. H. P. Stevens, and their laboratories have become widely known in connection with the paper and rubber industries.

Beadle contributed largely to technical literature; he was the author of "The Theory and Practice of Beating," and also published "Chapters on Papermaking," in collaboration with Dr. Stevens.

His work received many recognitions from learned and technical societies, including medals from the Royal Society of Arts, Société d'Encouragement pour l'Industrie Nationale (Paris), and the Franklin Institute (Philadelphia).

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.
United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—
 Patent number, date, name of patentee, and title of invention.
French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Feron S. Paris (3e).
 Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Desiccants; Comparison of the efficiency of some common—. M. V. Dover and J. W. Marden. *J. Amer. Chem. Soc.*, 1917. 39, 1609—1614.

Alumina was prepared from purified alum solution by precipitation with ammonia. The precipitate was washed with dilute ammonia, dissolved in hydrochloric acid, re-precipitated with ammonia, and washed with water and ammonia. The product was dried first at 100° C. and finally at 500° C. in a current of air dried over sulphuric acid. Calcium oxide was prepared by treating the nitrate with caustic soda, dissolving the hydroxide in hydrochloric acid, and re-precipitating with caustic soda. The hydroxide was then washed free from chlorides, and was ignited at 500° C. in a current of air free from carbon dioxide. Magnesium oxide was prepared in the same way as alumina. Cupric sulphate was prepared by three times recrystallising blue vitriol, drying at 100° C. and heating for some time at 400° C. In each case the freshly prepared desiccant was transferred to a U-tube whilst still warm. A known volume of moist air was aspirated at a uniform rate (1½ to 2 litres per hour) through a column of the desiccant, 30 cm. long by 15 mm. wide, and the residual moisture absorbed and accurately weighed in a counterpoised phosphorus pentoxide tube. Alumina proved to be a most efficient drying agent, but calcium oxide and magnesium oxide soon became exhausted. With cupric sulphate the colour showed that the first few cm. of the column of material was sufficient to absorb the moisture. From the results obtained by the author and by others, the weights of residual moisture in 1 litre of air at 25° C., after having passed a U-tube containing a 30 cm. column of the desiccant, are given as follow:—copper sulphate, 1.4 mgrms.; zinc bromide, 1.1; zinc chloride, 0.8; calcium chloride, 0.36; sulphuric acid (95.1%), 0.3; calcium bromide, 0.2; calcium oxide, 0.2; sodium hydroxide, 0.16; magnesium oxide, 0.008; alumina, 0.003; potassium hydroxide, 0.002 mgrm.

—J. H. P.

PATENTS.

Evaporators. The Griscom-Russell Co., New York. Assignees of R. C. Jones, Garden City, N.Y.. U.S.A. Eng. Pat. 103,820, Dec. 21, 1916. (Appl. No. 18,342 of 1916.) Under Int. Conv., Feb. 1, 1916.

A MULTI-COIL evaporator has a perforated baffle-plate arranged below the surface of the liquid and just above the coils, so that the vapour given off is directed to one side of the vessel and carries only a little entrained liquid with it. The vapour passes into a pipe extending upwards through the evaporator-head above the evaporator, and is discharged from the pipe through a nozzle against a ridge by which the vapour is divided into two converging streams which sweep round the evaporator-head to the outlet. The deposited liquid is returned by a pipe to the evaporator proper.

—W. H. C.

Concentration, evaporation, or distillation of liquids. J. Harvey, Roek Ferry, F. A. Hulme, Fornby, and The Chemical and Mechanical Processes Co., Ltd., Liverpool. Eng. Pat. 108,555, Aug. 30, 1916. (Appl. No. 12,255 of 1916.)

An ordinary evaporating apparatus has on its

outlet pipe a long continuation pipe and in it a length of piping or coil, the lower end of which is connected with the feed tank and the upper with the evaporator. The liquid in the feed tank passes through this pipe and is heated by the vapours from the evaporator, acting as a condenser at the same time. Any uncondensed vapour is condensed by means of a water spray placed below the preheating coil.—J. H. P.

Dust separator for pulverising mills. The Raymond Brothers Impact Pulveriser Co., Chicago, Ill. Assignees of R. A. Lechmann and W. B. Senseman, Chicago, and A. W. Raymond, Evanston, Ill., U.S.A. Eng. Pat. 105,763, July 24, 1916. (Appl. No. 5517 of 1917.) Under Int. Conv., Oct. 23, 1915.

A DUST separator for pulverising apparatus of the type in which the pulverised material is discharged by means of an air current, consists of a funnel-shaped separating chamber open at the top and having a discharge opening at the bottom which can be closed by a slide. A conical partition, having a central opening, is disposed across the separating chamber, to the upper open end of which a bag, formed of material pervious to air, and supported by a framework, is fixed. The pulverised material is led tangentially into the separating chamber, below the partition, and the space above the partition is connected by a pipe with the feed passage leading to the pulverising machine.

—W. H. C.

Waste heat of gas engines, incandescent slag, coke, and the like; Method for utilisation of the—. C. Semmler, Wiesbaden, Germany. Eng. Pat. 107,443, July 24, 1916. (Appl. No. 10,403 of 1916.)

A CIRCULATING medium which does not readily boil, for instance glycerin, calcium chloride solution, etc., is used to take up the waste heat and to give it up again to water or air in a suitable heat-exchanging apparatus. The circulating medium is heated only to a temperature below its boiling-point, so that it can be used under atmospheric pressure. Heat storing or dissipating devices are interposed in the system to deal with an irregular supply of waste heat. (See also Eng. Pat. Appl. 10,074 of 1916.)

—W. H. C.

Boiler gases; Apparatus for washing and utilising waste—. F. Sargent and H. C. Heaton, Chicago. Assignors to Babcock and Wilcox Co., Bayonne, N.J. U.S. Pat. 1,235,928, Aug. 7, 1917. Date of appl., Apr. 21, 1916.

THE waste gases are sprayed with water which then passes to the feed water heater, through which it travels in the opposite direction to the feed water. After leaving the feed water heater, the spray liquid is used to moisten the air for combustion.—J. H. P.

Vacuum drying apparatus. J. D. Taylor, London, and F. Shaw and Co., Ltd., Manchester. Eng. Pat. 108,130, Mar. 6, 1917. (Appl. No. 3325 of 1917.)

THE material is fed from a hopper by a rotary vacuum-tight plug into a steam-jacketed vacuum drying chamber. Within the chamber a screw conveyor passes the material to the smaller end of a tapering horizontal conveyor drum, from the wider end of which the dried material is discharged

to the atmosphere through an air-lock. Several tapering drums may be placed in series, one above the other, within the chamber.—W. H. C.

Drying apparatus for cattle bark, maize, or other like commodity. A. Mitchell, London, Eng. Pat. 108,132, Mar. 15, 1917. (Appl. No. 3805 of 1917.)

THE material is supported on a series of superposed endless bands which convey it through the drying chamber. The latter is formed by a collapsible frame covered on the inside and outside with asbestos sheets, with a layer of insulating material between the sheets. Air is drawn from the atmosphere through a dust filter by a fan and delivered through a refrigerating chamber, where it is dried, to a tubular air heater. The air is heated by the products of combustion from a furnace placed below, which pass round the tubes, and the warm air is delivered into the drying chamber through flues which pass below the floor, and are provided with a number of discharge nozzles.—W. H. C.

Drying and aerating machines. J. A. Sparks, C. E. and W. M. Clark, Elk, Kans., U.S.A. Eng. Pat. 108,520, Aug. 8, 1916. (Appl. No. 11,190 of 1916.)

THE apparatus consists of a hydro-extractor provided with a lid containing an air inlet in the form of a spout. The revolving basket sets up an inflowing current of air through the spout and through the material in the basket.—J. H. P.

Centrifugal dryer. G. H. Elmore, Swarthmore, Pa. U.S. Pat. 1,235,193, July 31, 1917. Date of appl., Sept. 6, 1912.

THE material is fed to the small upper end of a revolving conical screen by means of a hopper. Within the screen is a bell distributor mounted with a number of quick pitch conveyor flights; the distributor revolves in the same direction as the screen, but at a slightly different speed, thus tending to feed the material down the screen.—J. H. P.

Regenerative furnaces; Reversing valves and flues for —. B. Percival, Sheffield, Eng. Pat. 108,205, July 31, 1916. (Appl. No. 10,776 of 1916.)

SEPARATE water-sealed valve-boxes, separated by a considerable length of flue, are used for the gas and waste products of combustion respectively.—W. H. C.

Furnaces. P. Southwick, Birmingham, Eng. Pat. 108,566, Sept. 16, 1916. (Appl. No. 13,174 of 1916.)

A FRAME, formed from cast iron bars with mitred ends and secured by dovetail connections, is placed above the usual fire-bar frame, and passages are formed at the sides of both frames in the brickwork to admit air to the back of the upper frame. The air passes through slots in the vertical bars of the frame to the upper side of the fire-bars.—J. H. P.

Viscid material; Apparatus for reducing more or less — in bulk to the condition of a layer or film. A. Sonsthagen, West Ealing, and E. H. Bernhard, Ashurst, Kent, Eng. Pat. 108,504, Aug. 3, 1916. (Appl. No. 10,982 of 1916.)

THE material is supplied by a feed roller to a pair of oppositely moving rollers or to a roller and a fixed body or a belt. The rollers may move at the same or different speeds, and the thickness of the film is regulated by altering the space between the rollers and the speed of the feed-rollers.—J. H. P.

Centrifugal separator. T. H. Parker, San Francisco. Reissue 14,331, July 24, 1917. of U.S. Pat. 1,212,996, Jan. 16, 1917. Date of appl., June 9, 1917.

IN a separator, the rotary distributor has a central depression and is surrounded and partly covered by a shell having an opening at top and bottom. The shell is carried on a rotating sleeve and its upper part is surrounded by a receptacle with a downwardly inclined bottom and fitted with a discharge hole at the bottom and a supply pipe at the top. The material is fed through this pipe on to the revolving distributor, the light particles being discharged over the top of the shell and the heavy ones below it. The shell and distributor may be run at different speeds.—J. H. P.

Cleaning and heating air; Apparatus for —. W. F. Cox, Danville, Va. U.S. Pat. 1,233,555, July 17, 1917. Date of appl., Jan. 25, 1916.

A TANK containing liquid is supported on "staggered" guides between which "staggered" baffles formed of absorbent material are placed. The air passes between the guides and baffles, the latter being supplied with liquid from the tank above by wicks, and then through a screen or filter which is also supplied with liquid from the tank by wicks.—W. H. C.

Clarifier. O. M. Nilson, Assignor to United States Sugar Co., New Haven, Conn. U.S. Pat. 1,234,202, July 24, 1917. Date of appl., Dec. 14, 1916.

AN inner vessel serving as a heating flue is suspended within an outer vessel containing a fluid, and is partly surrounded by baffle plates. The fluid in the outer vessel is caused to flow in a tortuous path around the inner vessel and through vertical tubes extending through the inner vessel. The baffle plates are arranged so that the inner vessel can be removed without disturbing them. The outer vessel is provided with gutters and cocks for the scum and fluid contents.—J. H. P.

Dryers; Rotary —. W. E. Prindle, London, Ohio, U.S.A. Eng. Pat. 108,358, Aug. 3, 1916. (Appl. No. 10,991 of 1916.)

SEE U.S. Pat. 1,222,244 of 1917; this J., 1917, 583.

Drying-machines with rotary heating devices; Construction of —. R., W. G., and F. R. Simon, Basford, U.S. Pat. 1,237,110, Aug. 14, 1917. Date of appl., May 21, 1914.

SEE Eng. Pat. 12,237 of 1913; this J., 1914, 342.

Disintegrating machine. G. S. Higginson, London. U.S. Pat. 1,235,030, July 31, 1917. Date of appl., June 14, 1915.

SEE Eng. Pat. 14,891 of 1914; this J., 1915, 945.

Pyrometer. U.S. Pat. 1,234,203. See XXIII.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Alcohol as a source of power. W. T. Rowe, Bull. No. 8, Dept. of Chem., South Australia.

ALCOHOL possesses many advantages over petrol as a fuel for internal combustion engines. A greater degree of compression can be used and there is less trouble from "knocking." The Department has used a mixture of 95 volumes of pure alcohol and 5 volumes of water. Methylated spirit is more economical but would be improved by using better denaturing agents. There is a little difficulty in starting from "all cold" with alcohol, and it is advantageous to add a little petrol or ether. With engines specially designed

for alcohol, this fuel has an advantage over petrol, relative efficiencies of 28 and 16.5% respectively being quoted (see also this J., 1915, 336). Petrol and alcohol do not mix in all proportions, but petrol may be added to 95% alcohol up to equal volumes. Benzol will mix with alcohol in all proportions, and in some cases a solution of naphthalene in benzol is used. With regard to the Excise restrictions it would be an advantage to provide a system of methylation more adapted to a motor spirit: benzol, petrol or redistilled condensate from Pintsch gas are suggested as admirable denaturants for this purpose. The use of wheat for alcohol production renders the cost prohibitive, and the price of potatoes would require to be not higher than 23s. per ton. A good source of alcohol is found in molasses, of which in Australia fully a third is put to no use. Wood, according to the variety, will give 16 to 20 galls. of alcohol per ton. As regards the cost of alcohol, the working expenses, apart from the restrictions of the Revenue authorities, would appear to average about 5d. per gallon.—J. E. C.

Ammonium sulphate; Direct process for manufacturing — II. 53rd Report on Alkali, etc., Works, 1916, 21—50. (See this J., 1915, 1001.)

THIS process was kept under observation in two works. In these works the make of gas has on occasions reached 1200 cub. ft. per sq. ft. of box surface per 24 hours, and the volume of oxide in relation to gas has been 8.0 and 6.7 cub. ft. of oxide respectively per 1000 cub. ft. of gas; the crude gas is very imperfectly cooled before reaching the purifiers, and where cooling is more efficient the condensed moisture removes much of the ammonia. Under these conditions, moisture tends to condense within the system, and the use of a relatively dry oxide, as previously recommended, is considered fully justified. Observations of temperatures in the process indicate that satisfactory results are obtainable with temperatures considerably in excess of the limits previously laid down (about 0° F. both in the sulphiding and oxidation zones) under the existing conditions. Experience has confirmed the view that the activity of the oxide is markedly higher when sufficient ammonia is present in the crude coal gas to keep the oxide neutral or slightly alkaline, and in some works the life of the oxide has been considerably extended by supplying a controlled amount of ammonia to the boxes. The results of experiments suggest that the amount of ammonia required to maintain the oxide in a state of neutrality bears a direct relation to the amount of ferrous sulphate formed, and that the formation of ferrous sulphate is favoured by excessive moisture and possibly by low temperature. The bulk of the ammonia should be introduced to the first purifier, but it is considered desirable to admit a certain proportion to the second box in place of supplying an excess to the first box. Cyanogen recovery, by scrubbing the crude gas with ferrous sulphate, is regularly practised at one works, but removal of the hydrocyanic acid has not obviated purifier troubles. Notwithstanding the elimination of losses due to inefficient working, the recovery of ammonia in the process was only 18½ lb. (sulphate) per ton of coal carbonised in 1916, compared with 17 lb. in 1915. These figures raise doubt as to whether the amount of ammonia leaving the retorts is really so high as has been supposed, and preliminary tests tend to confirm this, but the subject requires further investigation.

Sulphiding of hydrated oxide; Experiments on the — 53rd Report on Alkali, etc., Works, 1916, 50—52.

CRUDE coal gas leaving a scrubber fed with gas

liquor containing about 1.95% of free ammonia (ammonia content of gas in one experiment 6.3 grs. per 100 cub. ft.) was passed downwards through Dutch bog ore contained in a model purifier. Samples of the oxide were dried at various temperatures and their efficiency compared with that of an equal volume of undried material at different temperatures and rates of flow. Oxide containing 16% of moisture (corresponding approximately to $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$) was markedly more efficient than an equal volume of oxide containing 37% of moisture ($\text{Fe}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$), or of oxide dried at 100° C. (Fe_2O_3), at both high and low temperatures. Under all conditions of hydration, the oxide showed a marked increase in efficiency at high temperatures: e.g., the relative efficiencies of air-dried oxide were 100 at 36° C. and 39 at 5° C.

Tar; Increasing the yield of — by lower temperature carbonisation. J. West. Gas J., 1917, 139, 379.

THE author gives details of tests relating to the effect of high and low temperature on the yield of tar. A four days' test with a coal of poor quality at temperatures of 1400° C. (2552° F.) and 978° C. (1793° F.) gave the following respective results:—Coal carbonised, 43.1 tons and 12.97 tons; gas made per ton, 11,491 cub. ft. and 7272 cub. ft.; total yield of tar (dehydrated), 259 galls. and 140 galls.; reduction in output of tar due to low temperature carbonisation, 46%. Tests on coal of good quality carbonised at temperatures of 1404° C. (2559° F.) and 1160° C. (2120° F.) gave the following results respectively:—Coal carbonised, 34.32 and 17.73 tons; gas per ton, 13,899 and 13,387 cub. ft.; yield of tar, 447 and 292 galls.; reduction in output of tar 34.7%. Tests on coal carbonised at high temperatures with the addition of steam to make blue water-gas gave a gas yield of 16,603 cub. ft. per ton and a tar yield of 20 gallons per ton, the latter figure being higher than any of the yields quoted at low temperatures. The low temperature tar is of very poor quality, and is made at a very great sacrifice of volume of gas, time taken up, and excessive costs, while the total output per day is materially decreased. Analysis shows that low temperature tar does not produce as good results in content of toluol and benzol as the high temperature product.—J. E. C.

Mineral oils; Oxidation of — by air. I. Effect of sulphur on the oxidation of hydrocarbons, with particular reference to asphalt. B. T. Brooks and I. W. Humphrey. J. Ind. Eng. Chem., 1917, 9, 746—748.

PETROLEUM oils, whether saturated, such as natural gasoline, or of the unsaturated type, like "cracked" gasoline, deteriorate much more rapidly by oxidation on exposure to the air than portions of the same oils which have been freed from sulphur by treatment with lead or copper oxides or metallic sodium. It is possible that oxidation of the sulphur compounds causes a simultaneous oxidation of other constituents. This view is supported by the fact that on heating petroleum residues with small amounts of sulphur, and shaking the mixture with natural gas, the product is much more fluid than that obtained by blowing air into the mixture. Asphalts of exceptional hardness may be made by the combined action of air and sulphur. For example, on air-blowing a sample of residue from a Mexican oil, to which 8% of sulphur had been added, for 31 hours at 220° to 230° C., the resulting product had a flowing point of 185° C., and a penetration of 7 mm. at 25° C. Another product made from the same residue, with the addition of 12% of sulphur, had a flowing point of 200° C., and a penetration at 25° C. of 5 mm. (100 gm. weight, No. 2 needle, 10 secs.). In practice, products as hard as this are seldom required, but the addition

of 3 to 5% of sulphur has a pronounced effect in producing hard asphalts in a much shorter time (e.g., 14 hours as against 96 hours) than can be obtained by air-blowing residues to which sulphur has not been added. Hence, too, residues relatively rich in sulphur will yield hard asphalts in less time, when blown with air, than those poor in sulphur.—C. A. M.

Bitumens; Effects of exposure on some fluid —. C. S. Reeve and R. H. Lewis. J. Ind. Eng. Chem., 1917, 9, 743–748.

EXPOSURE tests were made in a shallow box designed to exclude dust (J. Ind. Eng. Chem., 1913, 5, 15) upon samples of crude petroleum, oil asphalt, petroleum residue, and a water-gas tar preparation, and the results were compared with the behaviour of the same materials when used for the surface treatment of a limestone macadam road. At the end of two months the crude petroleum had lost 12.47% and 14.57% in weight respectively, the oil asphalts showed a slight increase in weight, whilst the Texas petroleum residue had increased 2.16% in weight, and showed a slight softening of the material, as indicated by the float test at 10° C. The tar preparation, which yielded only 2.1% of distillate up to 170° C., lost 7.29% in weight in the exposure test. The behaviour of the four products under service conditions was in general agreement with their relative behaviour in the exposure tests. The crude petroleum and the tar preparation developed a firm crust which was not displaced by traffic in rain and snow, whilst the Texas petroleum residue became soft during rainy periods throughout the year. On continuing the exposure tests for 12 months, all the samples excepting the petroleum residue showed a lower loss than during the previous period, whilst the residue showed a slight increase in fluidity. The amounts of fixed carbon and of bitumen insoluble in naphtha showed much greater increases than corresponded with the loss of volatile constituents. For example, in the case of a Trinidad crude petroleum, the loss on heating the sample for 10 hours at 163° C. was 28.31%, whilst the loss on exposure for 10 months was 26.60%, but the actual increases in fixed carbon for the same periods were 4.30 and 5.80% respectively. It is probable that polymerisation and intermolecular reactions have as much effect as evaporation in causing these changes.—C. A. M.

Action of illuminating gas on plants. Action of the gas on the germination of spores and seeds. Wehmer. See XVI.

PATENTS.

Peat; Apparatus for expressing liquid from —. J. W. Hinchley, London. Eng. Pat. 108,503, Aug. 3, 1916. (Appl. No. 10,976 of 1916.)

IN using the apparatus described in Eng. Pat. 101,782 of 1915 (this J., 1916, 1254), water, or the filtered expressed liquid, is pumped down through the grooves at the back of the strainers to prevent choking of the grooves or strainers.—J. E. C.

Fuel; Burning pulverised —. V. Z. Caracristi, Albany, N.Y., Assignor to Locomotive Pulverised Fuel Co. U.S. Pat. 1,234,870, July 31, 1917. Date of appl., May 25, 1914. Renewed Dec. 27, 1916.

A SERIES of columns of the fuel is delivered in a furnace, upwards and at different relative angles, towards a central combustion zone, and the flame is deflected, above the combustion zone, towards the rear and top of the furnace. Combustion is effected by means of preheated air delivered in the direction of the zone of combustion and of the deflected flame. Incombustible residuum is separated by impingement and gravity.—J. E. C.

Hydraulic mains used in connection with gas retorts and other carbonising plant. H. E. Bloer and J. B. Fenwick, York. Eng. Pat. 108,049, Aug. 15, 1916. (Appl. No. 11,510 of 1916.)

THE bottom of a hydraulic main is inclined towards one end, whereby the tar produced in any number of settings may be drawn off as produced. Division plates dipping into the tar and liquor are provided between the settings to form seals and thus allow of the isolation of any particular setting.—J. E. C.

Producing gas; Process and apparatus for —. H. L. Doherty, Assignor to The Improved Equipment Co., New York. U.S. Pat. 1,235,774, Aug. 7, 1917. Date of appl., Sept. 5, 1913.

AN automatically proportioned mixture of steam and air is forced through a deep bed of ignited fuel, the temperature being thereby maintained below the clinkering point. The steam is supplied by the exhaust from the engine driving a positive air blower and is introduced into the air blast main, a siphon being provided to remove condensed water.—J. E. C.

Burners [for blast-furnace gas, etc.] for boilers, stoves, and like heating appliances. J. J. H. Mackinlay, Shifnal, Salop. Eng. Pat. 108,185, July 25, 1916. (Appl. No. 10,139 of 1916.)

THE gas enters through the box, D, provided with a sight glass, E, into two upper gas tubes, C, which pass through the flue-plate, A, into the boiler

flue. The two tubes, C, end in a gas-box, F, from which the gas flows back through a common tube, G, mingles with the air which enters at I, and flows through the two tubes, H, J. The mixture burns at the open end of G, and the flame travels back over the tube, G, and around the two tubes, C.—W. H. C.

Oils; Apparatus for vaporising — for enriching coal and other gases. N. Swindin, London. Eng. Pat. 108,579, Oct. 4, 1916. (Appl. No. 14,003 of 1916.)

A SERIES of connected gas pipes are arranged one above the other. Each gas pipe contains a closed steam pipe provided with gills or helical fins. Oil is distributed by means of a tray fitted in notches in the gills or fins and having overflow lips and spreading devices. The oil may pass from gas main to gas main, by way of sealed overflows, in the opposite direction to the flow of gas.—J. E. C.

Oil gases; Purification of —. F. Tinker, Birmingham. Eng. Pat. 108,602, Nov. 4, 1916. (Appl. No. 15,785 of 1916.)

IN the purification of oil gases by the removal

of unsaturated gaseous hydrocarbons under the action of chlorine, the reacting mixture is cooled throughout its bulk by means of a cold inert liquid introduced as a spray or in thin films. The product of the reaction is preferably used as cooling liquid.—J. E. C.

Mineral oils; Treatment of — [to remove sulphur, etc.]. O. D. Lucas, London, T. C. Palmer, Dagenham, and F. M. Perkin, London, Eng. Pat. 108,019, July 17, 1916. (Appl. No. 10,039 of 1916.)

SULPHUR or other undesirable ingredient is removed from mineral oils by subjecting the latter, whilst heated, to the action of ammonia. The ammonia reacts with the sulphur and converts it into hydrogen sulphide and other compounds readily removable by subsequent chemical treatment. The oil may be forced at a high velocity and pressure through tubes in which it is heated above its normal boiling point and then allowed to expand suddenly, ammonia being previously dissolved in the oil or forced in as a gas.—J. E. C.

Hydrocarbons; Apparatus and method for the conversion of — F. B. Dehn, London. From Synthetic Hydro-Carbon Co., Pittsburgh, U.S.A. Eng. Pat. 108,333, June 29, 1916. (Appl. No. 9186 of 1916.)

THE hydrocarbons are passed on to heated pieces of metal contained in a perforated basket in order to convert them completely into the gaseous state. The gases pass down under pressure into a vertical cracking tube, heated to a suitable temperature, and containing a central shaft with a series of lateral vanes, to the ends of which short chains are attached. The shaft is kept in rotation, thus deflecting the gases and ensuring effective contact with the heating surface; at the same time the chains remove the carbon deposited on the outer wall. Underneath the cracking tube is a chamber in which the carbon collects, through which the gases pass on their way to the condensing apparatus. A baffle wall or curtain prevents the carbon from passing on with the gases, and by closing a valve the carbon can be removed during the operation. A by-pass connects the receiver of the condensed liquid with the supply tank to supply the necessary pressure to force the hydrocarbons into the cracking tube, or, if preferred, a force pump may be attached for this purpose. By controlling the temperature, pressure, and time of cracking, different products, such as gasoline, benzene, toluene, may be obtained as desired.—L. A. C.

Petroleum; Transforming crude — into petroleum of less density. F. B. Deakin, London. From M. E. Venturino, Buenos Ayres, Argentine. Eng. Pat. 108,496, Aug. 16, 1916. (Appl. No. 3251 of 1916.)

THE crude petroleum is heated in a retort cooled at the top by the controlled application of water or other liquid, thereby causing the vapours of higher boiling points than that of the required product to be condensed and again exposed to the cracking action at the bottom of the retort. The lighter vapours pass out at the top of the retort and are condensed. A mechanical scraper, operated at intervals from the outside, prevents the formation of a layer of non-conducting coke at the bottom of the retort. A chamber inside the retort, open at the bottom and closed at the top, enables the denser portions of the liquid to be drawn off and either stored, or burnt as fuel for heating the retort. The top half of the retort is separated from the bottom half by asbestos sheets to lessen the conduction of heat.—L. A. C.

[Oil] distilling apparatus. L. S. Flatau, St. Louis, Mo. U.S. Pat. 1,233,771, July 17, 1917. Date of appl., Oct. 1, 1915.

A DISTILLING apparatus comprises an inner oil

receptacle provided with a vapour dome, and an outer shell, the annular space between the two forming a steam boiler. The products of combustion from a heating chamber beneath the still pass upwards by way of a series of tubes passing through the annular boiler portion into a hood enclosing the dome.—J. E. C.

Petroleum distilling apparatus. S. Boru, Bartlesville, Okla. U.S. Pat. 1,234,124, July 24, 1917. Date of appl., Jan. 25, 1917.

PARALLEL lengths of chain extend along the still bottom from end to end, covering its entire bottom. An opening is provided through which the chain may be inserted and removed.—L. A. C.

Still. B. Gallsworthy, Port Arthur, Tex. U.S. Pat. 1,234,327, July 24, 1917. Date of appl., Apr. 12, 1915.

THE still is domed and fitted with a coiled oil inlet nozzle at the top and a similar one for steam at the bottom. It is divided into compartments by perforated partitions with alternate central and marginal perforations. Each compartment is provided with a cock, and the dome has diaphragms projecting upwards from opposite sides at an angle.—J. H. P.

Hydrocarbon oils; Treatment of — A. L. Brown, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,234,862, July 31, 1917. Date of appl., Aug. 6, 1915.

HYDROCARBON oil is treated with 0.1 to 0.2% of red phosphorus to prevent the formation of sediment.—L. A. C.

Unsaturated hydrocarbons; Process of making — B. E. Eldred and G. Mersereau, New York, Assignors to Chemical Development Co. U.S. Pat. 1,234,886, July 31, 1917. Date of appl., Aug. 6, 1912.

HYDROCARBON oil vapours are exposed for a brief period to a temperature of about 700° C., but not reaching 800° C., the reaction products immediately removed and quickly cooled. The issuing mixture is white and foggy, consisting of a permanent gas and unchanged oil.—L. A. C.

Gas; Cold-proof — and method of making the same. B. E. Eldred and G. Mersereau, New York. U.S. Pat. 1,235,777, Aug. 7, 1917. Date of appl., Aug. 6, 1912. Renewed Dec. 14, 1916.

HEAVY oil vapours are exposed for a short time, in narrow tubing free from coky carbon, to a temperature of about 700° C., and then cooled to from 0° to -8° C. to condense residual oil vapours, which should amount to not less than 10% of the original oil. The remaining gas is added in an "unfixed" condition to "permanent lean gas" to make a compound cold-proof illuminating gas.—J. E. C.

Hydrocarbon oils; Apparatus for treating — G. L. Rowsey, Assignor to The Illinois Refining Machinery Co., Quincy, Ill. U.S. Pat. 1,235,384, July 31, 1917. Date of appl., July 1, 1916.

THE apparatus comprises a still, and primary and secondary condensers arranged in series. The distillate from the primary condenser passes back to the conduit leading from the still. This conduit is heated in order to crack the returning heavy hydrocarbons, and is arranged so that it is in part beneath the point of its connection to the still, to prevent the return of the condensed liquid into the still.—L. A. C.

[Gasoline] filter. A. Storm, Thompson, Iowa. U.S. Pat. 1,235,395, July 31, 1917. Date of appl., Oct. 11, 1916.

A GASOLINE filter consists of a thin-walled receptacle

with a filtering medium stretching in an inclined plane entirely across it. The inlet pipe is beneath the filtering medium, and the outlet pipe above it, and each has its mouth pointing downwards. These pipes extend across the receptacle and serve to brace its sides.—L. A. C.

Waste liquor [from refining of mineral oils]; Process for treating —. E. H. Wright and J. F. Oakleaf, Olean, N.Y., Assignors to Vacuum Oil Co., Rochester, N.Y. U.S. Pat. 1,236,031, Aug. 7, 1917. Date of appl., June 11, 1914.

WASTE liquor from the acid and alkali treatment of mineral oils, containing sodium sulphonates and sodium sulphates in solution and a small quantity of suspended oil, is treated with a reagent capable of producing with the sodium salts an insoluble precipitate in which the oil is occluded. This precipitate is separated, dried, and distilled.—L. A. C.

Coke-ovens; Means for continuously operating —. J. Lütz, Essen, Germany. U.S. Pat. 1,236,727, Aug. 14, 1917. Date of appl., Aug. 5, 1913. SEE Ger. Pat. 263,767 of 1912; this J., 1913, 1058.

Acetylene gas; Means for storing compressed or dissolved —. T. G. Allen, London. U.S. Pat. 1,234,600, July 24, 1917. Date of appl., Jan. 30, 1917.

SEE Eng. Pat. 100,911 of 1916; this J., 1916, 918.

[Petroleum] oils; Process of treating —. A. M. McAfee, Bayonne, N.J. U.S. Pat. 1,235,523, July 31, 1917. Date of appl., Sept. 30, 1913.

SEE Eng. Pat. 22,244 of 1914; this J., 1916, 298.

Utilisation of the waste heat of gas engines, incandescent slag, coke, and the like. Eng. Pat. 107,443. See I.

Production of toluol, benzol, and other light hydrocarbons from heavy oils. Eng. Pat. 108,508. See III.

Closed oil-tester. [Flash-point apparatus.] U.S. Pat. 1,236,123. See XXIII.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Carbonising furnaces, or furnaces for reducing ores. J. G. Aarts, Dongen, Holland. Eng. Pat. 101,215, Aug. 8, 1916. (Appl. No. 11,203 of 1916.) Under Int. Conv., Aug. 13, 1915.

THE chamber walls of a carbonising or ore-reducing furnace are built of refractory material of such high specific heat and density that the heat capacity of the bricks in any horizontal plane is several times greater than that of the charge. The heating flues in the chamber wall are of such form that the heat-absorbing surface of the bricks is many times greater than the heat-imparting surface, and a number of baffles, transverse to the direction of the gas, may be introduced to increase the resistance of the flue. The radiating effect of the faces of the bricks is increased by embedding in the surface, material in crystallised form and of greater hardness than the charge. Graduated heating is brought about by insulating the various zones by asbestos, and by varying the composition of the bricks, substances such as silicon carbide, chromite, or graphite increasing the conductivity as compared with fireclay bricks. In each horizontal plane of the furnace the difference of

temperature between the heating wall and the charge is about 300° C., and the temperature of the heating flue ranges from 1500° C. to about 500° C. in the different zones.—J. E. C.

Organic refuse; Extraction of fals, ammonia, and the like from — [by destructive distillation]. Benton's Patents, Ltd., and W. A. Benton, Birmingham. Eng. Pat. 107,992, Apr. 20, 1916. (Appl. No. 5784 of 1916.)

THE organic refuse is subjected to distillation under reduced pressure, and in order that the process may be continuous the material is fed into the retort through a semi-rotary valve. The distilled substances pass from higher to lower zones of temperature and through a porous core in the material in the retort. The exit for the distillate consists of a semi-rotary valve which is cleaned, lubricated, and sealed by the issue of a sheet of steam between the valve and its casing. Suitable processes are applied to the distillate to separate the various constituents.—W. P. S.

Destructive distillation of carbonaceous substances. S. N. Wellington, London. Eng. Pat. 108,200, July 27, 1916. (Appl. No. 10,658 of 1916.)

COAL or similar carbonaceous material is heated in a vertical retort at a comparatively low temperature. Free space is allowed at the top of the retort, which is heated to a higher temperature than the lower carbonising section, and a mass of metal or other material is suspended in the heated free space to facilitate the decomposition of gases and vapours by means of radiant heat.—J. E. C.

Distillation of coal; Low temperature —. F. Lamplough, and Oil Extractors, Ltd., London. Eng. Pat. 108,343, July 28, 1916. (Appl. No. 10,726 of 1916.)

COAL is heated in a series of retorts by superheated steam admitted at the bottom. The hot gases evolved may be delivered to a gas main, or, by means of a by-pass, directed to the base of any particular retort to assist in the heating thereof.—J. E. C.

Carbonisation of coal and other carbonaceous matter. W. Anderson, Helensburgh, and J. Meikle, Glasgow. Eng. Pat. 108,509, Aug. 4, 1916. (Appl. No. 11,034 of 1916.)

VAPOURS distilled from oil are passed at a high temperature and pressure, through a retort containing carbonaceous matter, the vapours mingling with the gas evolved from the coal, etc. The apparatus comprises a still for oil distillation, a superheater communicating therewith, a retort, and a condenser.—J. E. C.

Rotary furnaces [for manufacture of carbon from vegetable matter]. R. Sumner, Cowley. Eng. Pat. 108,596, Nov. 1, 1916. (Appl. No. 15,592 of 1916.)

THE furnace comprises an inclined rotary tube, preferably ribbed or corrugated on its inner surface, and mounted between two superimposed fires.—J. E. C.

Electric incandescent lamps filled with argon. Allgem. Elektricitäts-Ges., Berlin. Eng. Pat. 102,441, Oct. 14, 1916. (Appl. No. 14,643 of 1916.) Under Int. Conv., Nov. 11, 1915.

IN an electric incandescence lamp small quantities of electro-negative gases or vapours, particularly phosphorus vapour, or substances evolving such gases or vapours, are introduced for the purpose of preventing the formation of arcs and thus permitting the use of argon free from nitrogen or containing a very small quantity thereof, as a filling for the lamp.—J. E. C.

Electric lamp; Incandescence — G. M. J. Mackay, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,234,060, July 17, 1917. Date of appl., Apr. 30, 1913.

AN incandescence lamp comprises a bulb, a tungsten filament therein, and a filling of nitrogen at an initial pressure of 0.2–50 mm. (say 10 mm.) of mercury for each sq. cm. of filament surface. Under these conditions the progressive "clean-up" of gas during the operation of the lamp produces a progressive decrease in cooling effect on the filament, approximately counterbalancing the progressive decrease in heat generated in the filament, due to the wasting away of the filament. Special claim is made for a lamp having a tungsten filament about 5 in. long and 5 mils (0.005 in.) diam., the bulb being filled with nitrogen at an initial pressure of about 2 mm. of mercury.—J. E. C.

Furnace-setting for destructive distillation of coal or other carbonaceous substances. S. N. Wellington, Assignor to Coalite, Ltd., London. U.S. Pat. 1,234,517, July 24, 1917. Date of appl., May 17, 1916.

SEE Eng. Pat. 7769 of 1915; this J., 1916, 1006.

Destructive distillation of carbonaceous material; Apparatus for — W. L. St. J. Prioleau, London. U.S. Pat. 1,237,094, Aug. 14, 1917. Date of appl., June 20, 1916.

SEE Eng. Pat. 9375 of 1915; this J., 1915, 1082.

Electrical heating apparatus and process of making the same. U.S. Pat. 1,234,973. See XI.

III.—TAR AND TAR PRODUCTS.

Dichlorophenols; Preparation and properties of the six — [Odour of the dichlorophenols and their anisols.] A. F. Holleman. Rec. Trav. Chim. Pays-Bas, 1917, 37, 96–107.

The following methods were used for the preparation of the six dichlorophenols. 2,6-Dichlorophenol. Melted phenol was treated with one molecule of chlorine, and the product distilled. The fraction boiling above 210° C. was treated with a second molecule of chlorine, then diluted with benzene, shaken with water, dried, and distilled. From the fractions boiling from 210° to 230° C., the 2,4-compound crystallised. The 2,6-compound was separated from the fraction boiling from 215° to 220° C. by extracting with sodium carbonate and acidifying. After recrystallisation from petroleum ether it melted at 67° C. It was also prepared by chlorinating *p*-nitrophenol with hydrochloric acid and potassium chlorate, reducing the product with iron and sulphuric acid, diazotising, and boiling with alcohol and sodium acetate. 2,4-Dichlorophenol was obtained as described above in the chlorination of phenol. It was purified by repeated crystallisation from petroleum ether, and vacuum distillation, and melted at 45° C. 2,5-Dichlorophenol was prepared by diazotising the corresponding dichloroaniline. It melted at 58° C. 3-Dichlorophenol was obtained by reducing 2,3-dichloronitrobenzene and diazotising the product. Vacuum distillation and recrystallisation from petroleum ether gave a product melting at 7° C. 3,4-Dichlorophenol was prepared by diazotising the corresponding amine. After recrystallisation from a mixture of benzene and petroleum ether, it melted at 68° C. and boiled at 53.5° C. (767 mm.). 3,5-Dichlorophenol was prepared from *symm*-trichlorobenzene by treating it with sodium methoxide and decomposing the anisol produced with concentrated hydrochloric acid. It melted at 68° C. The corresponding anisols were prepared by treating the dichlorophenols with dimethyl sulphate and caustic soda,

extracting with benzene, and distilling *in vacuo*. Their melting points are as follow: 2,6-Dichloroanisol, 10.1° C.; 2,4, 28° C.; 2,5, 24° C.; 2,3, 31° C.; 3,4, –8° C.; 3,5, 68° C. The kind and intensity of the odour of the chlorophenols vary considerably. The 2-, 2,3-, 2,4-, and 2,6-chlorophenols have odours resembling that of iodoform, and the 3-, 4-, 2,5-, 3,4-, and 3,5-isomers have odours similar to that of phenol. The odour of the 2-, 2,3-, 2,4-, and 2,6-chloroanisols is similar to that of acetophenone, the odour of the 3-, 2,5-, and 3,5-isomers is similar to that of anisol, and the odour of the 4- and 3,4-isomers is similar to that of anethol.—F. Sp.

Increasing the yield of tar by lower temperature carbonisation. West. See 11A.

PATENTS.

Tar oils, carbolic acid, cresylic acid, and like substances; Distillation of — W. R. Grimwade, Toorak, Victoria, Australia. Eng. Pat. 108,004, July 11, 1916. (Appl. No. 9770 of 1916.)

THE distillation of tar oils, carbolic acid, cresylic acid, or the like from coal tar, is conducted in a current of an inert gas, *e.g.*, nitrogen or carbon dioxide, introduced under pressure at the bottom of the still. The offensive odour of the distillates (which is stated to be due to the action of oxygen) is thus avoided, the still temperature is reduced with consequent fuel economy, the distillation is accelerated, and fractional separation is facilitated. —F. W. A.

Low temperature tars; Separating — *without distillation.* R. Maclaurin, Stirling. Eng. Pats. (A) 108,339 and (B) 108,448, July 21, 1916. (Appl. Nos. 10,263 of 1916 and 8603 of 1917.)

(A) True low temperature tars, *i.e.*, those characterised by the almost entire absence of aromatic hydrocarbons of the benzene series, of naphthalene and anthracene, can be separated from resinous matter by thorough agitation with one or more portions of a hydrocarbon oil at about 40° C. The mixture is allowed to settle, the resinous matter collecting at the bottom. The top layer, on purification, gives an oil suitable for lubrication. The addition of a small quantity of water during the last agitation ensures a more complete separation. (B) By agitating low temperature tar or oil at 40–50° C., with water containing 3% by volume of sulphuric acid, and then allowing to settle, three layers are obtained. At the bottom is resinous matter; above this, an acid layer containing basic matter in solution; and, on top, an oil. These are separated and purified. A better resin may be obtained by previously treating the tar or oil as specified in (A), thus removing the bulk of the resinous matter. (See also this J., 1917, 620.)—L. A. C.

Pitch or other viscous or solid tar products; Liquid and plastic compositions containing — G. L. Davies, London. Eng. Pat. 108,368, Aug. 15, 1916. (Appl. No. 11,551 of 1916.)

SOLID or very viscous tar products obtained as described in Eng. Pat. 16,908 of 1909 (this J., 1910, 1368) are dissolved in cresols or a mixture of cresols and tar naphthas, or, preferably, commercial cresylic acid. The mixture can then be applied with less heat, or without the use of heat at all, leaving after evaporation of the volatile solvents, a hard, waterproof coating.—L. A. C.

Light hydrocarbons; Production of toluol, benzol, and other — *from heavy oils.* W. Anderson, Helensburgh, and J. Meikle, Glasgow. Eng. Pat. 108,508, Aug. 4, 1916. (Appl. No. 11,033 of 1916.)

THE heavy oil (creosote oil, blast-furnace oil) is distilled under pressure in a specially constructed

still consisting of two superposed drums separated by a combustion chamber, the lower drum, or both drums, being traversed by fire-tubes. The two drums are connected by a downcomer and return tubes, the oils being fed into the upper drum by a pipe coaxial with the downcomer. The distillate is mixed with steam, and the mixed vapours passed through a superheater and then through suitable condensing apparatus.—L. A. C.

Benzyl chloride; Process of producing —. J. B. Conant, Cambridge, Mass. U.S. Pat. 1,233,986, July 17, 1917. Date of appl., Oct. 20, 1916.

A MIXTURE of toluene and bleaching powder or other suitable chlorine compound is treated with sulphur dioxide or other suitable gas, reacting with the bleaching powder to form chlorine, and the resulting benzyl chloride separated by distillation. —B. V. S.

Process for treating waste liquors [from refining of mineral oils]. U.S. Pat. 1,236,031. See 11A.

IV.—COLOURING MATTERS AND DYES.

p-Phenylenediamine (ursol); Product of oxidation of — by hydrogen peroxide. (Bandrowski's base, tetra-aminodiphenyl-*p*-azophenylene). A. Heiduschka and E. Goldstein. Arch. Pharm., 1916, 254, 584—625. J. Chem. Soc., 1917, 112, i., 482—485.

IN view of the use of a solution of hydrogen peroxide and *p*-phenylenediamine as a hair-dye, the reaction between these two substances, which has been cursorily examined by Erdmann (thus J., 1904, 1023), has been thoroughly studied by the authors in order to ascertain the influence of varying experimental conditions on the yield of tetra-aminodiphenyl-*p*-azophenylene. In all the experiments a constant amount of 10% sodium carbonate solution, which was found to have no appreciable effect on the oxidation, was added to destroy the acidic impurities in the hydrogen peroxide. In all cases, substances other than Bandrowski's base are produced in larger or smaller amounts. The theoretical yield of Bandrowski's base was calculated in accordance with the equation: $3C_6H_4(NH_2)_2 + 3H_2O_2 = C_{18}H_{18}N_4 + 6H_2O$. The influence of the concentration of the *p*-phenylenediamine was found by allowing aqueous solutions of *p*-phenylenediamine (1—4%) to react with 2.98% hydrogen peroxide (10% in excess of the theoretical quantity) for twenty-four hours at 18°—20° C. The yields of base were 6—16.3%, nothing approaching the amounts (80—90%) claimed by Erdmann ever having been obtained. The yield does not increase proportionately to the concentration. The effect of time was found by prolonging the period of reaction. After seven days, the yield of oxidation product was 30—40%, and after three months only 60%, of the theoretical. The influence of the amount of hydrogen peroxide (2.98% solution) was found by keeping the reaction mixture containing 1.88% of *p*-phenylenediamine at 18°—20° C. for twenty-four hours. With amounts of hydrogen peroxide increasing from 0.636 mol. to 3.636 mols. (per 1 mol. of *p*-phenylenediamine), the yield of Bandrowski's base increased proportionally from 4.7% to 27.7%. With yet larger amounts of hydrogen peroxide, impure products were obtained, 5 mols. of hydrogen peroxide yielding a black non-crystalline mass. Rise of temperature accelerated the reaction at the expense of the purity of the product, but its effect was unimportant within the range of temperature which the skin can endure. *p*-Phenylenediamine in solution can be estimated by precipitation as *p*-benzoquinonedichloroimide by an excess of

calcium hypochlorite solution, and it is thus shown that in the preceding experiments, after removal of the Bandrowski's base, the filtrates contain 40—60% of unchanged *p*-phenylenediamine after twenty-four hours, about 50% after thirty days, and appreciable amounts after three months; in addition, about 20% of the diamine has been oxidised to products which could not be isolated. Despite certain differences in properties, Erdmann states (*loc. cit.*) that the base obtained by oxidising *p*-phenylenediamine with hydrogen peroxide is identical with the tetra-aminodiphenyl-*p*-azophenylene $[C_6H_4 \cdot \begin{smallmatrix} N \cdot C_6H_4(NH_2)_2 \\ | \\ N \cdot C_6H_4(NH_2)_2 \end{smallmatrix}]$ obtained

by Bandrowski by oxidising an ammoniacal solution of *p*-phenylenediamine by atmospheric oxygen or a solution of its hydrochloride by potassium ferricyanide. The authors prepared the base by oxidising an ammoniacal solution of *p*-phenylenediamine by aqueous potassium ferricyanide (whereby it is obtained rapidly and almost quantitatively), and found that after purification with pyridine it has m. pt. 239°—240° C. and no water of crystallisation. The base is obtained sometimes in very slender bronze leaflets, at other times in dark brown crystals, and yet again in large, dark red prisms according to the method of preparation. Estimations of the nitrogen by the Dumas method gave the expected results; those obtained by the Kjeldahl method were 2—3% too low. Bandrowski's base can be diazotised in the usual way, but the diazo solution does not combine with amines or phenols and does not yield characteristic products on boiling.

Separation and identification of food-colouring substances. Mathewson. See XIXA.

PATENTS.

Disazo dyestuffs; Wool —, and a process of making same. E. Anderwert and H. Schobel, Assignors to Soc. of Chem. Ind., Basle, Switzerland. U.S. Pat. 1,233,742, July 17, 1917. Date of appl., Apr. 9, 1917.

ONE molecule of the tetrazo derivative of a 3,3'-diaminodiphenylmethane compound, e.g., 3,3'-diamino-4,4'-dimethylphenylmethane, is combined with 2 mols. of an azo dyestuff component of which at least 1 mol. is a naphtholsulphonic acid, e.g., with 2 mols. of 1,4-naphtholsulphonic acid, to give a red wool dye fast to light and to fulling.—F. V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Fibres from various sources. Bull. Imp. Inst., 1917, 15, 7—23.

Jute from Egypt. The sample was grown at Cairo from Indian seed and had been prepared by a special (alkaline) process; it was inferior in colour and lustre to Indian jute of fair quality prepared by retting. Owing to the method of preparation the loss on hydrolysis was abnormally low; the presence of a small amount of alkali, owing to insufficient washing, was detrimental to quality. The sample was valued at £36—£37 per ton, as compared with Calcutta jute at £41.

Sida rhombifolia fibre, known as "vivane," was received from Swaziland. The sample was clean, well prepared but somewhat harsh; it was of good strength and about 2 ft. in length. Fibre of this quality but 4 ft. in length would be worth £3 to £4 less than Calcutta jute. A larger sample received later was not well prepared; it was harsh, mostly matted and gummy, and poor in lustre; the cellulose content (70.5%) was low and the hydrolysis losses abnormally high on this account. The fibre was valued at only £17—£18 per ton with Calcutta jute at £28; such a fibre would be saleable for mixing with jute when the price of the latter is high. Better results should be obtainable by improved methods of retting.

Hibiscus cammabinus fibre from Rhodesia. This fibre had not been well prepared and the retting appeared to be uneven; the strength was irregular and the length varied from 4 to 6 ft. The hydrolysis results were high and the cellulose content low. The sample was inferior in colour, softness, and general appearance to Bimlipatam jute prepared in India from the same plant. The fibre was valued at £27 per ton, as compared with Calcutta jute at £32; the low quality is attributed to inexperience in the retting process. *Hibiscus* fibres of the same species were obtained from Egypt and from Nyasaland. The Egyptian fibre had been prepared by a special treatment and had not been washed free from alkali; it was consequently inferior in appearance and deficient in lustre. Two samples from Nyasaland gave high hydrolysis losses and low cellulose content; one was of moderate quality and the other distinctly inferior.

Nettle fibre from India. The sample consisted of uneven, very tangled fibre, brown to pale buff in colour, with many green portions. It had apparently been prepared merely by mechanical treatment and contained most of the gum and was coated with bark. The length of staple was mainly about 3 ft. 6 in., composed of extremely fine ultimate fibres 4—5 in. in length. In the rude state the fibre would have little value but might be used in coarse jute goods. The de-gummed fibre would hardly be a suitable substitute for flax or ramie, being deficient in strength and spinning qualities. The fibre might be obtained sufficiently clean and free from gum and bark by retting to be used in admixture with jute or hemp, but if retting were not practicable in India, it might be saleable in the form of clean bark ribbons prepared by scraping away the outer bark as in the preparation of China grass.

Sisal hemp from Rhodesia. A sample of sisal

hemp grown under experimental conditions was found to be exceptionally well prepared. The length of staple was mainly 2 ft. 6 in. to 3 ft. and if this had been slightly greater the sample would have ranked among the first-class materials of this species.

Furcraea fibre from Southern Rhodesia. This fibre was fairly clean and well prepared but inferior to previous samples from the same source; the cellulose content (72%) was lower and loss on acid purification higher, indicating insufficient washing. The length varied from 3 ft. to 8 ft., mostly 5 ft. to 5 ft. 6 in. Better removal of the pith by brushing and sorting of the fibres into more uniform lengths would increase the value. Another sample of *Furcraea gigantea* fibre from S. Africa was insufficiently cleaned but of good length and strength; it was estimated at a value of £20—£21 (Oct., 1915) but would be readily saleable at a much higher price if properly prepared.

Asclepias fruticosa fibre from S. Africa. This is locally known as "melkbosch" and is widely distributed. Two samples were examined which, however, were not well prepared and contained a good deal of bark. The staple was not sufficiently long (mostly 20—22 in.) to compare favourably with sisal. The fibre was harsh and of poor lustre, but exceptionally rich in cellulose (52%) and might possibly be found useful as a basis for nitrated explosives. In comparison with sisal hemp at £50, the samples were valued at £32—£38 per ton.

Kapok from the Sudan and Togoland. The Sudanese sample was not quite free from pod residues, but after cleaning it yielded a floss of excellent quality equal in resiliency to Java kapok. In Togoland a trade in kapok has been developed by the Germans, 9 tons having been exported in 1913. The quality of the sample bale received may be regarded as normal, and it is considered that encouragement should be given to the development of the industry.

Asclepias fruticosa floss from S. Africa. This floss is somewhat brittle and inferior in resiliency to kapok, and corresponds to the material known in the trade as "Akund." Its value in this country is considerably lower than that of kapok and it is not so suitable for the manufacture of life-saving appliances.

Seed hairs of Ipomoea albivenia from S. Africa. This material is known locally as Kafir or Natal cotton and resembles harsh unginned cotton of dark cream colour. The fibres are triangular in section, untwisted, and much thinner in the walls than cotton fibre, and only about 0.3 in. long. The raw fibre is much more absorbent than raw cotton, but it lacks the strength and spinning qualities of the cotton fibre. The material contains only 77.3% of cellulose and does not appear to be a very promising commercial article, though it might fetch a low price as a stuffing material considerably inferior to kapok.—J. F. B.

Wood; Chemistry of.—III. Mannan content of the gymnosperms. A. W. Schorger. J. Ind. Eng. Chem., 1917, 9, 748—750.

The method of determining mannan in various woods was to digest the sawdust with hydrochloric acid, precipitate the resulting mannose by phenylhydrazine, and calculate the mannan from the weight of the mannose phenylhydrazone. There was a pronounced difference in the results obtained with the conifers (*Gymnospermæ*) and hard-woods (*Angiospermæ*). The amounts of mannan found in 22 species of conifers, including firs, spruces, and pines, ranged from 1.44% (*Arbor vitæ*) to 9.22% (Cuban pine), but no mannan was present in the six hard-woods examined, including basswood, sugar maple, yellow birch, ash, and aspen. The proportion of mannan is usually greater in the

sap wood than in the heart wood; it decreases from the base upwards, but is fairly constant in transverse sections of the heart wood.—C. A. M.

Paper-making materials; Some new —. Bull. Imp. Inst., 1917, 15, 1-7.

Ecdeicola manostachya is a rush-like plant found only in Western Australia; the stems or so-called "leaves" are erect, rigid, rather slender, and vary in length from 2 to 5 ft. Treated in the same way as esparto grass (Oran) they gave approximately the same yield of pulp, 44% on the air-dry material, but the pulp was inferior in appearance, darker, and more difficult to bleach; it was also contaminated with yellow specks of a wax or resin, which could be removed by a more severe treatment, at the expense, however, of the yield of cellulose. This plant is regarded as a practicable material for the manufacture of paper pulp in the country of origin.

Neoboutonia macrocalyx is a tree growing to a height of 50-60 ft. and a diameter of 15-20 ins. in the East African Protectorate. It is extremely abundant and grows rapidly. The timber is of little value on account of its "woolly" nature, being very soft and light. Treated by the soda process under the same conditions as spruce, it yielded 46% of pulp of good quality as compared with 42% from spruce wood. The fibres are shorter than those of spruce, but the pulp bleaches well and yields a strong paper.

Brachystegia Randii is a tree which forms extensive forests in Mashonaland. The timber is of little value, though it is used for hut building. Ribbons of the inner bark have been examined, and a cordage fibre of inferior quality prepared, but being much interlaced it was not suitable for spinning. On digestion with 20% of caustic soda the bark yielded 33-34% of pulp of a dark colour, giving a strong brown paper. The pulp bleached easily and yielded a white opaque paper of good quality. The bark might be considered as a substitute for *Adansonia* bark but of lower commercial value from the point of view of yield; the economic difficulties of its transport from Rhodesia, however, would be considerable.—J. F. B.

Paper; Photomicrography of the structure of —. M. B. Hodgson. J. Ind. Eng. Chem., 1917, 9, 782-784.

Cross sections of paper stocks will afford information of the structure, and especially of the penetration of materials such as Indian ink into the paper. The sections are best prepared by mounting the paper between two pieces of gelatin-coated film the surfaces of which have been moistened to adhere to the paper. Outside the films are placed two pieces of moderately dry Castille soap, and the whole is fixed in the microtome with the paper edge normal to the edge of the blade.

—C. A. M.

Paper; Photometer for the measurement of the translucent effect of —. C. F. Sammet. J. Ind. Eng. Chem., 1917, 9, 784-785.

Two movable, standard, white backgrounds, inclined at an angle of 30° towards the source of light, are mounted on a track, with the light between and slightly below them. Above the zero point on the track there is a prism and eyepiece placed so as to reflect the light from the backgrounds into adjacent fields. After adjusting the blocks so that the fields match in luminosity, a sheet of paper is placed over the left-hand block, whilst a second piece is placed over the other block, with black velvet between. This block is now moved towards the light until the luminosity of the fields again appears the same, and the distance moved is an expression of the amount of light transmitted by the paper to the velvet and

then absorbed. The reading obtained with a given paper substituted in the formula— $100(1 - b^2/a^2)$ —gives a value for the comparison of the approximate percentage loss of light due to the absorption by the velvet. In this formula a represents the total scale reading, and b the distance which the block is removed from zero.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid; Possible adulteration of —. J. R. Withrow. J. Ind. Eng. Chem., 1917, 9, 771—776.

ATTENTION is drawn to the possibility of nitric acid being adulterated by the addition of sodium nitrate or other sodium salts, and dilution of the solution to the required sp. gr. with water. Nitric acid of sp. gr. 1.381, when saturated at 15° C. with sodium nitrate, contains 3.24% of the salt, and has a sp. gr. of 1.399. A saturated mixture of sp. gr. 1.380 will contain 4.83% of sodium nitrate and 8.30% of water. In like manner, nitric acid of sp. gr. 1.381 will dissolve 12.62% of sodium sulphate, giving a sp. gr. of 1.416, whilst a saturated mixture of sp. gr. 1.374 will contain 12.62% of sodium sulphate and 15.15% of water. Hence, the determination of the sp. gr. and of the NO_3 content of nitric acid ought always to be accompanied by an evaporation test for dissolved salts.

—C. A. M.

Ammonia oxidation; Chemical control of —. P. J. Fox. J. Ind. Eng. Chem., 1917, 9, 737—743.

For the determination of the ammonia in the entering gas, the Cumming absorber, described by Edwards (Bureau of Standards, Techn. Paper 34, 1914), effects complete absorption, and by its use it is possible to determine the ammonia without making a titration. A measured quantity of standard acid is placed in the absorber and coloured with an indicator, and the gas is made to bubble through the liquid until the colour changes. The theoretical dry air-ammonia mixture should contain 14.33% of ammonia. The method of absorption by means of standard alkali of the acid formed from the nitrogen peroxide (NO_2) is not applicable to the exit gas from the oxidation, owing to the large amount of condensed water from the hot gas interfering with the measurement of the volume, and also to the possibility that sufficient oxygen may not be present to oxidise all the nitric oxide to nitrogen peroxide. To obviate these difficulties the following method is suggested:—The gas is aspirated from the outlet pipe, but before reaching the absorption apparatus it is mixed with a measured quantity of oxygen or air in sufficient quantity to convert all the nitric oxide into nitrogen peroxide. The mixture is drawn through two absorption vessels, the first of which contains standard alkali solution, and the second standard alkali solution containing 1% of hydrogen peroxide. By this arrangement ammonium nitrite remains in the first vessel, where there is no hydrogen

peroxide to oxidise it. To prevent condensation of water, the sample of gas should be taken through a capillary tube as close to the catalyst as possible. Test experiments showed that the alkaline 1% hydrogen peroxide yielded about 6 c.c. of oxygen in the determination, and it is therefore advisable to make a correction for this amount. As an alternative efficient absorbent agent sulphuric acid may be used, the gases being previously mixed with oxygen as described above. For the determination of very small amounts of ammonia in the exit gases, the best method is that of oxidation by means of sodium hypobromite, and measurement of the resulting nitrogen in a gas burette. The author has worked out the following formula for calculating the efficiency of the process:—

$$\text{Efficiency} = \frac{V_{no}}{V_{nh_3}} = \frac{V_{no} (1/b - 1.25)}{fc + V_{no}}$$

where V_{no} is the volume of nitric oxide, V_{nh_3} is the volume of ammonia in the entering gas mixture, b is ratio of ammonia to the volume of the entering gas mixture, and fc is the volume of residual gas collected in the aspirator bottle of the testing apparatus, corrected as described below. If the hypobromite test shows that ammonia has passed through the catalyst unchanged, the equation must be modified as follows:

$$\text{Efficiency} = \frac{V_{no} + V_1}{V_{nh_3}} = \frac{(V_{no} + V_1) (1/b - 1.25)}{V_{no} + 0.75 V_1 + fc}$$

where V_1 is the volume of the unoxidised ammonia. The correction to be applied to the volume of gas in the aspirator bottle reduced to standard pressure and temperature, f , is

$$fc = f + 0.5 (V_{no} + V_1) - V_{ox},$$

where V_{ox} represents the vol. of oxygen added.

—C. A. M.

Pyrites; Determination of the "explosibility" of — as well as of the available sulphur and the sulphur content of its cinders. C. R. Gyzander. J. Ind. Eng. Chem., 1917, 9, 776—780.

THE explosive property of certain varieties of pyrites interferes with the burning of the ore in lumps, since the dust produced by the bursting of the lumps fills up interstices and prevents free access of air. The "explosibility" or crumbling quality of an ore may be quantitatively determined by heating the sample in a covered dish at a high temperature until no further change is observed, and then cooling, screening, and weighing the material which remains on a screen of a certain size, whilst passing through a next larger size. It has been claimed that a gradual pre-heating of the ore will minimise the effect of "explosion," but in the author's experiments 24 hours' pre-heating at 120° to 340° C., had no apparent effect in diminishing the "explosive" quality. But even in the case of non-crumbling ores, the sulphur may be given up slowly during the combustion, so that to find the available sulphur content of an ore it is necessary to determine the rate of change compared with that of some other ore which behaves normally and contains a known amount of available sulphur. For this purpose, 2 grms. of the ore, crushed to pass a 50-mesh sieve, is placed in a thin-walled electro-quartz dish. Three such dishes of uniform size and thickness of wall, each containing a charge of ore, are heated at 1000° F. (538° C.) in a sheet-iron rack in an electric furnace. After successive intervals of 15 mins., or longer if necessary, the dishes are separately withdrawn, and the reaction stopped by placing 5 grms. of sodium carbonate on the top of the ore. The sulphur in each is then determined by breaking up the mass, fusing it

with 5 grms. of sodium nitrate, dissolving the melt in hydrochloric acid, separating the silica, and precipitating with barium chloride. From the amounts of sulphur found the rate of change may be calculated.—C. A. M.

Potash ; [Blast-furnace flue dust,] a new source of —. H. T. Cranfield. J. Bd. Agric., 1917, 24, 526—530.

THE fine dust deposited in or around the flues, ovens, boilers, etc., in which the waste gases from iron blast-furnaces are utilised, contains appreciable quantities of potassium, mainly as sulphate and chloride. Twelve typical samples were found to contain from 2.97 to 15.89% of total (acid-soluble) and from 1.23 to 9.25% of water-soluble potash (K_2O); while the salt obtained by extracting other samples with hot water contained from 39.74 to 41.84% K_2O . In view of the number of furnaces in operation and the quantity of dust produced, the author considers this to be the most important source of potash yet discovered in this country.—W. E. F. P.

Reh or saji mitti for the manufacture of commercial alkalis ; Possibility of utilising —. A. H. Silver. Indian Trade J., Jan. 26, 1917. Agric. J. India, 1917, 12, 477—480.

THE deposits of *reh* or *saji mitti*, occurring as efflorescences on *usar* lands, are composed mainly of sodium carbonate, sulphate, and chloride, and may be divided into two main classes according as the carbonate or sulphate predominates. The soluble salts from deposits of both classes contain Na_2CO_3 , 70—90 and 1—10, Na_2SO_4 , 1—10 and 60—85, and $NaCl$ 5—20 and 5—20%, respectively ; by fractional crystallisation it was found possible to eliminate practically all the sodium chloride in each case, and thus to obtain crude sodium carbonate and crude sodium sulphate for use as such or in the manufacture of caustic soda and soda ash respectively.—W. E. F. P.

Chlorine in chlorides ; Iodometric determination of —. G. Torossian. J. Ind. Eng. Chem., 1917, 9, 751—752.

FROM 0.12 to 0.5 gram. of the chloride is thoroughly mixed with about 2 grms. of finely powdered manganese dioxide, and the mixture is introduced into a round-bottomed flask. The delivery tube from the flask passes through the cork of a long tube, which is immersed in a cylinder of cold water, and contains 100 c.c. of potassium iodide solution (25 grms. per litre). After the addition of 50 c.c. of dilute sulphuric acid (1:1), the delivery tube is attached, and the flask is slowly heated, with constant shaking, until the contents boil, when the heating is continued intermittently, with occasional agitation, for about 5 minutes, until all chlorine has distilled into the iodide solution. The glass tubing is then rinsed into the absorption tube, and the contents of the latter made up to 200 c.c., and titrated with $N/10$ sodium thiosulphate solution which has previously been standardised against pure iodine. The method is also applicable to the determination of chlorine in fluorides, any hydrogen fluoride liberated having no influence upon the final results.—C. A. M.

Ferricyanides ; Determination of — by titration with permanganate. C. de Coquet. Bull. Soc. Pharm. Bordeaux, 1917, No. 3. Ann. Chim. Analyt., 1917, 22, 160—161.

A SOLUTION containing about 0.5 gram. of ferricyanide, is heated to boiling and then treated with a few fragments of aluminium and a small quantity of sodium hydroxide solution. The

reduction of the ferricyanide is complete in about 20 mins.; the solution is then diluted, filtered, slightly acidified with sulphuric acid, and titrated with $N/10$ permanganate solution. Each c.c. of $N/10$ permanganate solution is equivalent to 0.033 gram. of potassium ferricyanide. The method may be used to determine ferricyanide in mixtures, such as certain compounds used in photography, which contain uranium nitrate, iron-ammonium citrate, and copper chloride. The mixture is dissolved in water, and sodium hydroxide solution is added as long as a precipitate forms; the mixture is then filtered and the filtrate treated with aluminium as described.—W. P. S.

Carbonates in limestone and other materials ; Determination of —. J. F. Barker. J. Ind. Eng. Chem., 1917, 9, 786—787.

THE following rapid method of determining carbonates in limestone, etc., gives results agreeing within 0.25% with those obtained by standard methods:—The acid reservoir is charged with 40 c.c. of hydrochloric acid (sp. gr. 1.15), the graduated stem of the hydrometer is disconnected, and a 10 gram. weight is attached at B. The hydrometer is then placed in a cylinder of water, and the depth of immersion on the scale, C, noted, after which the weight is removed, and powdered limestone is introduced into the reaction chamber until the instrument is immersed to exactly the same point. The graduated stem is now attached, and water is introduced, drop by drop, until the hydrometer is immersed to the zero mark. The instrument is now raised, and the stop-cock, D, is turned, so that acid runs into the reaction chamber. As the carbon dioxide escapes the hydrometer rises, until at the end of the reaction, the reading on the stem at the surface of the water gives the percentage of calcium carbonate equivalent to the carbon dioxide in the sample. A correction of + or - 0.5 is made for each 1° C. rise or fall in the temperature between the two readings. The weight of carbon dioxide left in the

flask is counterbalanced by the loss of moisture escaping with the gas.—C. A. M.

Silver and sulphides ; Course of the reaction between —. (Hepar test.) F. L. Hahn. Z. anorg. Chem., 1917, 99, 118—122. J. Chem. Soc., 1917, 112, ii., 371.

THE blackening of metallic silver by hydrogen sulphide or soluble sulphides, used as a qualitative test for sulphur, is sometimes represented as taking place in the absence of air, with liberation of hydrogen, and sometimes as a reaction with oxygen, the former hypothesis being adopted in most recent text-books. When precautions are taken, to exclude air, silver may be boiled for hours with sodium sulphide solution without evolution of hydrogen, the metal being unchanged, blackening taking

place immediately air is admitted. Hydrogen sulphide may also be passed through water in which silver is placed without any blackening. The presence of oxygen or hydrogen peroxide causes immediate blackening.

Cerous oxalate; Decomposition of — in a reducing or inert atmosphere, and a new property of the higher oxides of cerium. W. S. Chase. J. Amer. Chem. Soc., 1917, 39, 1576—1582.

CEROUS oxalate was very carefully purified and then decomposed by heat in a Hoskins combustion furnace fitted with a Pt—Pt Rh thermocouple. A temperature of 550° C. was found to be the lowest at which the carbonate resulting from the decomposition of the oxalate was completely decomposed. The residue obtained in hydrogen or nitrogen atmospheres is a very dark, blue-black, amorphous powder. At ordinary temperatures, if drawn directly into the air from a hydrogen atmosphere, it fires and burns vigorously to cerium dioxide. This phenomenon does not occur when a nitrogen atmosphere is used; it is due to absorbed hydrogen. The residues from the hydrogen and nitrogen atmospheres gave the same analytical results, indicating that the product is a mixture of ceric oxide, a lower oxide or oxides, free carbon, and adsorbed air. When heated in air to 400°—500° C., it fires, forming the dioxide. At lower temperatures it is stable, though at 200° C. oxidation of the carbon takes place, causing a rise in temperature. The hydrogen absorbed in the residue prepared in a hydrogen atmosphere amounted to 10—11 c.c. per grm. of residue. A stream of nitrogen passed over the residue at 550° C. removes the hydrogen, but in no case was the formation of ammonia detected, thus indicating that the hydrogen is held mechanically.—J. H. P.

Tantalum chloride; Study of — with reference to its use in the determination of the atomic weight of tantalum. G. W. Sears. J. Amer. Chem. Soc., 1917, 39, 1582—1587.

TANTALUM pentachloride exists as a stable compound in an atmosphere of dry nitrogen or dry air, but a trace of moisture is sufficient to hydrolyse it. It does not occlude chlorine. It was found that a high degree of accuracy could not be obtained when tantalum chloride was weighed in a vessel with a ground joint, owing to diffusion of moisture through the joint, and when weighed in sealed tubes volatilisation of the glass during the sealing operation affected the accuracy of the results. It seems that tantalum chloride is unsuitable for use in work where a high degree of accuracy in analysis is desired.—J. H. P.

Hydrogen peroxide; New method for the determination of —. G. S. Jamieson. Amer. J. Sci., 1917, 44, 150—152.

A KNOWN volume of hydrogen peroxide suitably diluted with distilled water (e.g., 50 c.c. of commercial peroxide to 500 c.c.) is measured into a 500 c.c. glass-stoppered flask containing 10 c.c. of a 10% solution of sodium hydroxide and a measured volume of standard sodium arsenite solution in excess of that required by the hydrogen peroxide. The flask is gently agitated as the solution is run in and then allowed to stand for two minutes. Forty c.c. of concentrated hydrochloric acid is then cautiously added, the stopper inserted, and the flask violently shaken. Six or seven c.c. of chloroform is then added and the unoxidised sodium arsenite is titrated with standard potassium iodate solution, the contents of the flask being well shaken after each addition. The end point is marked by the disappearance of the iodine colour from the chloroform. The original amount of sodium arsenite, less that determined by the iodate titration, gives the amount oxidised by the hydrogen peroxide. N/5 Sodium arsenite solution

and an equivalent sodium iodate solution are found most suitable for use. This method gives accurate results, and is not influenced by the presence of organic preservatives.—I. A. C.

PATENTS.

Nitric acid from ammonia; Process of making —. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,233,564, July 17, 1917. Date of appl., Oct. 12, 1916.

A HOT mixture of ammonia and air is passed upwards through a mass of coarse particles of a suitable catalyst, the temperature of which is adjusted by passing a cooler mixture of air and ammonia through a conduit embedded in the catalyst. Spent catalyst is withdrawn from the bottom of the chamber and fresh material supplied at the top.—B. V. S.

Ammonium nitrate; Manufacture of —. F. W. Howorth, London. From Norsk Hydro-Elektrisk Kvaestof Aktieselskab, Christiania. Eng. Pat. 101,090, July 24, 1916. (Appl. No. 10,422 of 1916.)

SOLUTIONS of ammonium nitrate act as absorbents for both ammonia and nitrous gases. One part of a dilute solution of ammonium nitrate is saturated with ammonia and the other part with nitrous gases, and the two liquids are mixed to obtain a stronger neutral solution. The operations may be repeated at will until a concentrated solution is obtained or the solid salt separates.—B. V. S.

Ammonium sulphate; Manufacture of —. W. G. Adam, London. Eng. Pat. 108,698, Dec. 13, 1916. (Appl. No. 17,940 of 1916.)

COMMERCIAL ammonium sulphate, which usually contains from $\frac{1}{2}$ % to 2% excess acid, is neutralised by passing ammonia gas through it in any convenient way.—B. V. S.

Soluble glass; Manufacture of —. R. M. Caven, Nottingham. Eng. Pat. 108,372, Aug. 21, 1916. (Appl. No. 11,848 of 1916.)

A FINELY-SUBDIVIDED neutral silicate which has been ground in the dry state is mixed with 25 to 38% of its weight of water, and the mixture is heated to a temperature between 70° and 100° C., under atmospheric pressure, until the mass becomes vitreous in structure. Over 95% of the solid product is readily soluble in water.—J. B. C. K.

Silicate-glasses; Treatment of — and preparation of useful products [soluble silicates] therefrom. J. W. Spensley, J. W. Battersby, and E. S. Holmes, Manchester. Eng. Pat. 108,576, Sept. 29, 1916. (Appl. No. 13,882 of 1916.) Addition to Eng. Pat. 11,959, May 14, 1914 (this J., 1915, 834).

IN the manufacture of soluble silicates by the method described in the earlier patent, the hydrated silicate, as it leaves the wet-grinding drum of the apparatus, is subjected to a further heat-treatment, in order to facilitate or render more complete the formation of a solid and uniformly hydrated product. The temperature limits named in the patent are 100° and 170° F.

(38°—77° C.) and the heating should be sufficiently gradual to ensure that the whole mass is uniformly affected and that no local overheating occurs. The cooling should also be gradual.—J. B. C. K.

Felspar; Method of utilising —. J. Rhodin. Chiswick. U.S. Pat. 1,232,977, July 10, 1917. Date of appl., Dec. 4, 1914.

FELSPAR is ground, and is mixed with a small quantity of a sodium salt, such as sodium chloride. A mixture of sulphur dioxide, steam, and air is then passed over the heated material, and the sulphuric acid produced is condensed. The residue is leached to extract the soluble potassium sulphate, and the insoluble matter that remains is utilised for the manufacture of Roman or Portland cement.—J. B. C. K.

Silicates; Process of decomposing —. L. L. Jackson, Assignor to O. C. Horney, New York. U.S. Pat. 1,233,273, July 10, 1917. Date of appl., June 16, 1916.

SILICATES are decomposed by mixing with 1 part by weight of lime (CaO) and 5 parts of water, and heating under pressure.—J. B. C. K.

Silicates; Process of decomposing —. H. W. Charlton, Jones Point, N.Y., Assignor to Kaolin Products Corporation. U.S. Pat. 1,234,626, July 24, 1917. Date of appl., Dec. 8, 1916.

AN alkali-bearing silicious material, such as glauconite (green-sand), is digested with a solution of calcium chloride and milk of lime, below 190° C. and at a pressure below 200 lb., for 2 to 4 hours, whereby a solution containing potassium chloride is obtained.—J. B. C. K.

Nepheline-syenite; Process of treating —. H. T. Kalmus, Brookline, Assignor to The Exolon Co., Cambridge, Mass. U.S. Pat. 1,234,905, July 31, 1917. Date of appl., June 28, 1915.

NEPHELINE-SYENITE is dissolved in an acid and the silicon and aluminium are separately precipitated and removed from the solution. The aluminium compound is then fused in an electric furnace, in order to obtain on cooling a crystalline product. The solution of the syenite may be effected by sulphitation, and aluminium and silicon separated from the solution by fractional desulphitation.—J. B. C. K.

Alunite; Method of treating —. F. K. Cameron, Washington, D.C. U.S. Pat. 1,233,977, July 17, 1917. Date of appl., Jan. 8, 1916.

ALUNITE is calcined at 500°—550° C. to obtain maximum formation of soluble aluminium salts and minimum evolution of oxides of sulphur. The calcined material is extracted with water, the dissolved alum separated and calcined with the formation of potassium sulphate, alumina, and oxides of sulphur, chiefly the trioxide. The potassium sulphate and the alumina are recovered, and the sulphur trioxide is used for treatment of the residue from the first calcination with the formation of aluminium sulphate.—B. V. S.

Salt-brine; Process for purifying —. B. Harlsuch, East Lansing, Mich., Assignor to The Buckley and Douglas Lumber Co. U.S. Pat. 1,235,202, July 31, 1917. Date of appl., Apr. 26, 1916.

A PURIFYING agent is generated within the brine by aid of an electric current passed through the brine by means of spaced electrodes. Precautions are taken to maintain the purifying agent in a pure condition by preventing the chlorine gas, set free by the action of the current, from acting upon it.—J. B. C. K.

Hydrogen peroxide; Method of manufacturing —. J. Pattek, Karlsruh, Germany. U.S. Pat. 1,234,380, July 24, 1917. Date of appl., Mar. 4, 1914.

A SOLUTION of ammonium persulphate is treated with sulphuric acid, and the hydrogen peroxide formed is separated rapidly from the resulting solution.—J. B. C. K.

Hydrogen peroxide; Method of producing —. H. A. Doerner, Assignor to The Chemical Products Co., Denver, Colo. U.S. Pat. 1,235,664, Aug. 7, 1917. Date of appl., Feb. 7, 1917.

CARBON dioxide gas under pressure is passed into water cooled to 0° C., and the mixture is agitated while at the same time barium peroxide is introduced into the mixture. An excess of carbon dioxide must be preserved during the reaction.—J. B. C. K.

Hydrogen sulphide; Production of —. R. F. Bacon, Pittsburgh, Pa., Assignor to Metals Research Co., New York. U.S. Pat. 1,235,953, Aug. 7, 1917. Date of appl., Nov. 10, 1915.

A MIXTURE of sulphide ore or concentrate with a small proportion of lime is treated with steam at a temperature which is gradually increased to about 700°.—W. E. F. P.

Hydrocyanic acid; Production of —. C. Beindl, München, Germany. Eng. Pat. 7260, May 14, 1915.

SEE Ger. Pat. 281,723 of 1911; this J., 1915, 612.

Formic acid; Production of —. G. Bredig, Karlsruhe, Assignor to R. Koepf und Co., Oestrich, Germany. U.S. Pat. 1,235,426, July 31, 1917. Date of appl., July 21, 1915.

SEE Eng. Pat. 9762 of 1915; this J., 1915, 1207.

Alkali perborates; Electrolytic process of making —. O. Liebknecht, Frankfurt, Germany, Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pats. 1,235,904 and 1,235,905, Aug. 7, 1917. Date of appl., Jan. 6, 1916.

SEE Eng. Pats. 160,154 and 100,153 of 1916; this J., 1917, 137 and 83.

Sodium percarbonate; Manufacture of —. W. Weber, Düsseldorf, and F. Noll, Benrath, Assignors to Henkel und Co., Düsseldorf, Germany. U.S. Pat. 1,237,128, Aug. 14, 1917. Date of appl., July 8, 1916.

SEE Eng. Pat. 100,997 of 1916; this J., 1916, 963.

Radio-active; Process for rendering liquids —. S. Saubermann, Berlin. U.S. Pat. 1,236,213, Aug. 7, 1917. Date of appl., June 14, 1915.

SEE Eng. Pat. 7385 of 1915; this J., 1915, 1208.

Calcium hypochlorite; Manufacture of —. G. Pistor and H. Reitz, Griesheim, Assignors to Chem. Fabr. Griesheim-Elektron, Frankfurt, Germany. U.S. Pat. 1,236,978, Aug. 14, 1917. Date of appl., Aug. 25, 1914.

SEE Ger. Pat. 282,746 of 1913; this J., 1915, 715.

Extraction of fats, ammonia, and the like from organic refuse Eng. Pat. 107,992. See 11b.

VIII.—GLASS; CERAMICS.

Glass; Art of colouring —[by exposure to rays of short wave-length]. H. Rosenthal. J. Ind. Eng. Chem., 1917, 9, 734—736.

GLASS may be artificially coloured by exposing it to short wave lengths of light from a quartz mercury arc, X-ray tubes, or special tubes for producing negative electrons. Definite results may be obtained by the use of a Coolidge, water-cooled, self-rectifying tube, in which an anode terminal of tungsten is supported on a rod of molybdenum, whilst the cathode consists of a tungsten spiral which can be electrically heated. The vacuum in this tube remains constant under all conditions, and unless the filament is heated the tube shows no electrical conductivity in either direction. The penetration of the rays is increased by increasing the voltage of the terminals. For colouring optical lenses, using a tube giving a current of 160 milliamperes at 50 kilovolts, an exposure of 2 mins. produces a light colour, an exposure of 4 mins. a medium colour, and an exposure of 10 mins. a dark colour. Thin, colourless glass is coloured uniform tints by this treatment, but thick glass (over $\frac{1}{4}$ in.) shows a gradation of colour from the exposed side. Porcelain teeth may be coloured by this method, and, by the use of stencils, coloured designs may be printed on porcelain ware. The less valuable gems are also changed in colour. For example, kunzite was changed from an amethyst to an emerald green colour after a few minutes' exposure. If the composition of the white glass is known, it is possible to predict beforehand the resulting colour. The action is molecular and is not confined to the surface of the glass; it is also reversible. Although the colouring of purple glass thus treated is due to manganese, the colour is not identical with that produced by chemical reactions of manganese in glass.—C. A. M.

PATENTS.

Insulator; Electrical —. F. M. Locke, Victor, N.Y. U.S. Pat. 1,233,486, July 17, 1917. Date of appl., Aug. 28, 1916.

SILICA, to at least 70%, boric oxide, alumina, lithia, and an alkali are fused together to form a homogeneous body, having a coefficient of expansion of less than 0.0000056.—B. N.

Clay and kaolin; Process for the treatment of — by elutriation. B. Schwerin, Assignor to Elektro-Osmose Akt.-Ges. (Graf Schwerin Ges.), Frankfurt, Germany. U.S. Pat. 1,233,713, July 17, 1917. Date of appl., Aug. 4, 1915.

To separate clay and kaolin from slime, the material is suspended in water and the degree of dispersion then increased, so that when the material is allowed to settle a fractional sedimentation takes place. Slime substantially free from kaolin, and kaolin containing less than 30% of water are deposited.—W. F. F.

Metal and other melting furnaces. Eng. Pat. 108,084. See X.

IX.—BUILDING MATERIALS.

Oxidation of mineral oils by air. Effect of sulphur on the oxidation of hydrocarbons, with particular reference to asphalt. Brooks and Humphrey. See IIA.

Effects of exposure on some fluid bitumens. Reeve and Lewis. See IIA.

Modification of the cobaltinitrite method of determining potassium. Hoff and Schwartz. See XXIII.

PATENTS.

Cement, mortar or concrete; Method of manufacturing a compound for making watertight —. Z. Morikami, Hiogo Ken, Japan. Eng. Pat. 100,886, June 27, 1916. Under Int. Conv., July 10, 1915. (Appl. No. 9043 of 1916.)

To make waterproofing material for adding to cement, mortar, or concrete, a mixture of fat or resin, 100 parts, caustic soda of 20° B. (sp. gr. 1.16), 20—22 parts, is boiled for 5—7 hours and milk of lime, 300 parts added, and the mixture boiled for four hours. The resulting calcium soap is skimmed from the surface, dried, and mixed with powdered burnt alum, 10 parts.—W. F. F.

Mixing concrete; Machines for —. H. Thornton, Stanningley, Yorks. Eng. Pat. 108,626, Dec. 14, 1916. (Appl. No. 17,971 of 1916.)

A BATCH-MIXING machine of the revolving drum type is fitted with internal mixing blades arranged in the following order: one pair of equal-sided V-shaped blades, one unequal-sided V-shaped blade, one pair of W-shaped blades, and another unequal-sided V-shaped blade. These blades extend the full width of the drum and their apices are in line with the periphery of the drum and at right angles to its axis.—A. B. S.

Cement-burning apparatus. L. P. Basset, Montmorency, France. U.S. Pat. 1,233,166, July 10, 1917. Date of appl., June 19, 1915.

A HEATING chamber or furnace, the length of which is many times its width, is provided at the material-outlet end with an injector for air and fuel, and at the opposite end with a horizontal pipe, extending into the furnace and bent at the end. A blast of air in the same direction as the draught through the furnace is delivered through this pipe at a point in the furnace where the temperature is about 900° C.—A. B. S.

Waste gases from Portland cement, lime and other kilns; Apparatus for utilising —. F. Schott, Heidelberg, Germany. U.S. Pat. 1,234,396, July 24, 1917. Date of appl., Dec. 30, 1912.

A WATER-TUBE boiler or other steam generator is fitted into a chamber built between a cement kiln and chimney, suitable baffle-plates and deflectors being placed so as to cause the waste gases from the kiln to circulate around the boiler. Pockets are provided for collecting dust from the gases.—A. B. S.

Pavements or paving mixtures; Method of making —. G. B. McGrath, Washington, D.C. U.S. Pat. 107,549, Feb. 28, 1917. (Appl. No. 2977 of 1917.)

A MINERAL aggregate consisting of gravel and sand is graded as usual to various sizes and mixed so that the voids or spaces between the particles are filled with the next smaller size of grains. The volume of the voids in the aggregate prepared as above is then determined, and a desired percentage of this volume is filled by incorporating the aggregate with a definite quantity of a filler prepared by mixing finely pulverised material with bituminous material up to the limit of its absorbing power, the quantity of bituminous material required being determined previously. The particles of mineral aggregate, before being mixed with the hot filler, may be coated with bituminous material.—A. B. S.

Plastic surfacing material, and process of producing same. J. C. Mertens, Chicago, Ill. U.S. Pat. 1,235,989, Aug. 7, 1917. Date of appl., May 8, 1916.

A SURFACING material for roads is made by mixing preheated, pulverised limestone and shale and hot liquefied bitumen in the proportion of 84% limestone and shale, and 16% bitumen.—A. B. S.

Artificial-stone slabs; Manufacture of —. M. I. Poznanski, Geneva, Switzerland. U.S. Pat. 1,234,692, July 24, 1917. Date of appl., Mar. 11, 1916.

FIBROUS vegetable matter is treated with a cold alkaline solution and then mixed with cement water.—A. B. S.

Sand-lime bricks; Manufacture of —. H. W. Charlton, Jones Point, N.Y. U.S. Pat. 1,235,766, Aug. 7, 1917. Date of appl., Apr. 13, 1917.

ONE part of lime is digested with five parts of water under a steam pressure of 225 lb. per sq. in. for 1–3 hrs., so as to form a hydrate with less than one molecule of water of hydration for each molecule of calcium oxide present. The product is mixed with sand and made into bricks which are then kept for 8–12 hrs. under a steam pressure of 100–135 lb. per sq. in.—A. B. S.

Cement; Acid- and waterproof — and method of making the same. C. C. Meigs, Assignor to Electro-Chemical Supply and Engineering Co., Philadelphia, Pa. U.S. Pat. 1,237,078, Aug. 14, 1917. Date of appl., Nov. 6, 1916.

SEE Eng. Pat. 108,278 of 1917; this J., 1917, 965

Method of utilising felspar. U.S. Pat. 1,232,977. See VII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

γ-Iron; Determination of the curve of transformation of — into α- and β-iron and of the curve of saturation of γ-iron by cementite by means of the methods of quenching and hardness. P. Saldau and P. Goerens. Rev. Soc. Russe de Métall., 1914, 1, 789–824. Rev. Mét., 1917, 14, Extraits, 65–74.

AFTER an historical account of the determination of these transformation curves, experiments are described which have been made with a series of pure Krupp steels, with carbon ranging from 0.11 to 1.51%. The specimens were in the form of discs 5 mm. thick, cut from rods 20 mm. in diameter, and pierced with a hole 4 mm. in diameter, in order to increase the cooling surface. They were heated in an electrically heated salt bath to 1050° C., cooled slowly in the bath to the required temperature, kept constant for 15 minutes, and then rapidly quenched in ice water. Four similar specimens were always treated at once. After grinding off a layer 1 mm. thick, the steels were examined micrographically and tested for hardness both by the Shore and Brinell methods. The micrographic results are represented graphically, and show that the γβ transformation follows a curve (GO) whilst the γα transformation follows a straight line (OS), the point O being at 780° C. and 0.35% C. The cementite line (SE) is straight. These lines all lie somewhat above those found by Carpenter and Keeling by the thermal method. The curves determined by means of hardness tests are in very good agreement with those determined micrographically. By plotting the hardness against the carbon content at each temperature, hardness isotherms are obtained which clearly mark the limits of solid solution. The maximum hardness, both by the Shore and Brinell methods, occurs at 0.63% C after quenching at 780°, 880°, or 1000° C. The maximum hardness of a steel containing 1.54% C occurs after quenching from 830° C., which is below the saturation curve, the steel then being a mechanical mixture of martensite and cementite.—C. H. D.

Iron and steel; Apparatus for measuring the electrical resistance of bodies at high temperatures, and the use of this apparatus in determining the critical points of —. P. I. Saldau. Rev. Soc. Russe de Métall., 1915, 1, 655–690. Rev. Mét., 1917, 14, Extraits, 76–81.

THE metals to be tested are used in the form of rods 50 mm. long and of 5 mm. diameter, which are polished and then annealed under a layer of two parts of barium chloride and one of potassium chloride at 1050° C., and slowly cooled. The specimens are then tested in a vertical electric furnace in a current of coal gas free from oxygen, the temperature and resistance being measured simultaneously (see Eng. Pat. 12,993 of 1915; this J., 1916, 1116).

The values of Ar, and Ac, were found to be the same, whilst the other critical points are different on heating and on cooling. The position of the curves of transformation in the iron-carbon system obtained by this method are in close agreement with those found by the thermal method (see preceding abstract). A new critical point is clearly indicated at 980° C. in all the steels examined. This is taken to indicate that, starting from this temperature, the growth of the austenite crystals is no longer proportional to, but is more rapid than the increase of temperature; hence the ratio of surface to volume diminishes rapidly, and the conductivity consequently increases. Benedicks' linear formula for the influence of dissolved elements on the resistance of austenite does not hold good, the resistance following a curve, as in the case of other solid solutions. Evidence is given from the form of the curves for the existence of a new allotropic form of iron above 900° C. Eutectoid steel has a higher resistance than steels of neighbouring composition. The resistance of quenched steels is not a linear function of the composition, but follows a curve.—C. H. D.

Cementation of iron. I. A. Fechtchenko-Tchopovsky. Rev. Soc. Russe de Métall., 1915, 1, 480–510. Rev. Mét., 1917, 14, Extraits, 91–95. (Compare this J., 1916, 892.)

CYLINDERS of mild steel, containing C 0.13, Si 0.015, Mn 0.60, P 0.05, S 0.04, and N 0.012%, were hardened in mixtures of wood charcoal with varying proportions of potassium ferrocyanide. Heating was continued for 4 hours at each of the temperatures selected. The nitrogen content of the case-hardened layer is insignificant at high temperatures, but increases as the temperature of hardening falls, being greatest at 700° C. Penetration of nitrogen at 700° C. continues for some hours at a diminishing rate. It does not occur in the absence of ferrocyanide. Nitrogen increases the hardness (Brinell) of the superficial layer by about 17 kilos. per sq. mm. for each 0.1% N. At the ordinary case-hardening temperatures nitrogen has no influence on the hardness. The effect of barium carbonate on cementation has also been studied quantitatively. At a given temperature, the actual quantity of barium carbonate which remains unchanged is greater, the higher the proportion in the original mixture, the ratio of the two being constant for the same temperature and time of cementation, but diminishing either with increasing duration or increasing temperature. The ratio BaCO₃:BaO is also constant for a given temperature and time. The diminution of carburising power is proportional to the barium oxide content. Barium oxide in small quantity renders the case-hardened layer irregular, and in large quantity destroys the layer. The best results are obtained with a mixture of 70% of wood charcoal and 30% of anhydrous sodium carbonate, which gives a rapid, vigorous, and uniform cementation. The depth of penetration is independent of the volume of carburising mixture used, but the hypereutectic

layer is less marked, the smaller the volume in proportion to the size of the object being hardened. This layer is less developed when a gas furnace is used than when the heating is electrical.—C. H. D.

Mild steel; Formation of free cementite in—. A. L. Babochine. Rev. Soc. Russe de Métall., 1915, 8, 561—571. Rev. Mét., 1917, 14, Extraits, 81—83.

Using small specimens of a mild steel containing C 0.17, Mn 0.39, Si 0.026, P 0.059, and S 0.069%, heated in a salt bath to avoid decarburisation, free cementite makes its appearance in the pearlite when the cooling takes place at the rate of 17° per minute between 793° and 691° C., and at the rate of 0.3° per minute between 694° and 674° C. The temperature to which the steel is heated is of little importance, but it is essential that the cooling through A_1 be very slow. Re-solution on heating takes place much more slowly than the deposition of cementite from solid solution on cooling. Manganese hinders the formation of free cementite if present to the extent of more than 0.6%. The lower the carbon and manganese and the lower the rate of cooling, therefore, the greater should be the brittleness of the steel.

—C. H. D.

Tool steels; Forms in which cementite appears in hypereutectic—according to their thermal treatment. N. G. Iljin. Rev. Soc. Russe de Métall., 1915, 1, 488—494. Rev. Mét., 1917, 14, Extraits, 83—85.

The forms assumed by the cementite in relation to the temperature of initial heating, velocity of cooling, and time of heating at a given temperature, have been studied in a steel containing C 1.27, Mn 0.28, Si 0.21, P 0.035, and S 0.020%. The cementite network increases in coarseness with the temperature of initial heating. The slower the cooling, the less tendency for the appearance of needle forms in the pearlite. A long stay at 700° C. favours the formation of granular cementite, especially after heating to a high temperature followed by slow cooling.

—C. H. D.

Manganese; Determination of—in iron and steel according to the bismuth method. H. Kinder. Chemikerkommission des Vereins deutscher Eisenhüttenleute. Stahl u. Eisen, 1917, 37, 197—202. J. Chem. Soc., 1917, 112, ii., 389—390.

In continuation of previous work on the estimation of manganese by the permanganate (this J., 1913, 510) and chlorate or persulphate (Stahl u. Eisen, 1915, 35, 918) methods, the Commission has examined the data concerning the bismuth process, using sodium bismuthate or bismuth tetroxide. The method is not suited for purposes of investigation, and cannot be recommended for the works laboratory because of its complicated nature and the necessity of keeping the temperature below 25° C. (increase of temperature causes low results for Mn). The Volhard-Wolff permanganate method is suitable for investigations, and can be used in the examination of ores, pig iron, steel, and ferromanganese. It can be employed equally well in hydrochloric or nitric acid solution, but sulphuric acid solutions are to be avoided. The presence of chromium is immaterial if the precipitated zinc oxide is removed; molybdenum and vanadium are without influence, but cobalt, which is usually only present in small amount, causes high results. The chlorate process can only be employed in nitric acid solution, and is particularly suitable for iron and steel; it is less accurate for estimating small amounts of manganese and for ferromanganese. Considerable quantities of chromium cause slightly high results. The persulphate process is adapted to works practice because of its rapidity. The presence of

considerable quantities of chromium or cobalt makes the end-point difficult to detect, on account of the yellow or pink colorations which they impart to the solutions.

Electrometric titration; Apparatus for—depending on the change of oxidation potential, and its application to the determination of small quantities of chromium in steel. G. L. Kelley, J. R. Adams, and J. A. Wiley. J. Ind. Eng. Chem., 1917, 9, 780—782.

An apparatus is described which has been designed to give very accurate results in the method of electrometric titration devised by Hildebrand (J. Amer. Chem. Soc., 1913, 35, 869) and modified by Kelley and Conant (this J., 1916, 966). It consists essentially of a wooden box with a metal upright, which carries the motor for driving the agitator, the electrodes, and the two burettes for the oxidising and reducing solutions. By means of this apparatus it is possible to determine chromium in steel more accurately than by any other method, duplicate results agreeing within 0.001%. The permanganate solution is conveniently standardised by titration with sodium oxalate, which in turn is compared with ferrous sulphate, whilst the chromate is finally titrated by adding an excess of ferrous sulphate and titrating the excess with permanganate. In each case corrections for the end-points must be found by means of blank titrations. All these titrations, with the exception of that of the sodium oxalate, may be most accurately made by the electrometric method. Allowance must be made for characteristic differences at the end-points of the reactions. Thus, in titrating a chromate solution the addition of ferrous sulphate almost always produces an anomalous rise, whilst in titrating a permanganate solution the phenomenon is less regular and not so pronounced. In titrating chromate solutions the end-point is indicated by an abrupt change in potential, whereas in the case of permanganate solutions the addition of from 0.2 to 0.4 c.c. of ferrous sulphate solution, after disappearance of the pink colour, often causes only a gradual change in potential. This difficulty may be overcome by adding ferrous sulphate in excess until there is a pronounced change in potential, then adding permanganate solution gradually, until the addition of two or three drops causes no further change. On now adding ferrous sulphate solution, drop by drop, a sharp and definite end-point is obtained.—C. A. M.

Zinc alloys; Analysis of—. Mossbacher. Z. öffentl. Chem., 1917, 23, 113—115. J. Chem. Soc., 1917, 112, ii., 389.

DETAILS are given of a rapid method for the full analysis of zinc alloys. After dissolving in concentrated nitric acid and evaporating to one-third bulk, sulphuric acid is dropped into the middle of the liquid, and heating is continued until white fumes are evolved. Water and alcohol are added, and after several hours the lead sulphate is collected. The precipitate is ignited in a crucible which has just previously been heated with a drop of sulphuric acid. Copper is precipitated as sulphide and heated with sulphur in hydrogen in a silica crucible. Aluminium and iron are precipitated from the filtrate, after removal of hydrogen sulphide, by adding hydrogen peroxide, and then, rapidly, a large excess of ammonia. By adding a little Congo-red, that part of the colloidal precipitate which always adheres to the glass is made clearly visible. Iron is estimated volumetrically in a separate portion.

Pyrolusite; Evaluation of—. E. Rupp. Arch. Pharm., 1916, 254, 135—137. J. Chem. Soc., 1917, 112, ii., 390.

To 0.2 gm. of very finely powdered pyrolusite are

added 3 grms. of potassium iodide, 3 grms. of sodium phosphate, 10 c.c. of water, and 10 c.c. of official (25%) phosphoric acid. The mixture is well shaken for one minute, and kept for thirty to sixty minutes with occasional shaking; about 50 c.c. of water is then added, and the liberated iodine is titrated with $N/10$ -thiosulphate with starch as indicator. A reappearance of the blue coloration indicates that the pyrolusite has not been sufficiently finely ground.

Titanium ores; Distribution and uses of —.
Bull. Imp. Inst., 1917, 15, 82—98.

The more important titanium minerals (rutile and ilmenite) are briefly described, and an account is given of their occurrence and distribution throughout the world. Titanium is used chiefly in the purification of iron and steel, for which purpose the carbide or a ferro-alloy is generally employed, the high melting point (1850° C.) and low specific gravity (5.17) of titanium precluding the use of the pure metal. The carbide is prepared by reducing a mixture of the ore and carbon in the electric furnace, the product consisting of microscopic particles of titanium carbide held in a matrix similar to grey cast iron; such material, containing 15—20% Ti and known as "ferro carbon-titanium," is the principal form in which titanium is at present employed for steel purification in the United States. Ferro-titanium, containing 10—75% Ti and only 0.12—0.75% C, is produced in quantity by reduction with molten aluminium in the electric furnace; but alloys of German origin are usually obtained by the ordinary aluminothermic process. The injurious effects of dissolved nitrogen upon steel are counteracted by titanium which, at 800° C., combines with nitrogen to form titanium nitrides; titanium also prevents segregation of the sulphur, phosphorus, and carbon and has the effect of concentrating the blowholes in the pipe cavity. In the case of ferro-alloys the best results are obtained with ferrotitanium containing 10—15% Ti, and an alloy of this composition is now specified in American (U.S.) practice. The alloy is added as the steel is run into the ladle (*i.e.*, after recarburisation and the addition of the necessary ferromanganese and ferrosilicon), 0.5% of the weight of the molten charge being usually sufficient. Although chiefly employed for treating rail steel, the use of titanium for other steels is steadily increasing. The quantity of titanium-treated steel rail produced in the United States has decreased considerably during recent years, owing to the substitution of open-hearth for the Bessemer steel formerly employed; titanium appears to be generally less beneficial to the former than to the latter. Alloys of titanium and silicon containing 5—70% Ti and 20—75% Si are also used in the iron and steel industry, while cupro-titanium containing 5—12% Ti is employed for degasifying copper and its alloys. To a limited extent titanium compounds are employed in various non-metallurgical industries. Thus, the carbide is used as a constituent of electrodes for arc lighting; the oxalate and various double oxalates are employed as mordants and for dyeing leather; while titanous chloride and sulphate find uses in the textile industry by reason of their powerful acid-reducing properties.—W. E. F. P.

Metals and metalloids [titanium, zirconium, and boron]; Preparation in a pure state of highly reactive —. E. Podszus, Z. anorg. Chem., 1917, 99, 123—131. J. Chem. Soc., 1917, 112, ii., 373—374.

For the preparation of titanium and zirconium, a steel bomb is used, closed by a strong screw and sealed with molten lead. The reduction mixture, consisting of sodium and titanium chloride or

potassium zirconium fluoride, is introduced in an atmosphere of hydrogen or carbon monoxide, several clean iron balls being added. The bomb having been closed, the whole is revolved for twenty to forty hours at about 200° C. to bring about an intimate mixture. Heating strongly for a few minutes starts the reaction. When a large excess of sodium is used, vapour may escape through the lead seal. The bomb is cooled from the top downwards, so that the lead may be solid before the pressure falls. The element is obtained in a minutely crystalline, highly reactive form. Titanium of 99.7% purity, and zirconium of 99.3% purity have been thus obtained, but the method fails to give pure boron.

Apparatus is described for the preparation and purification of boron trichloride. Reduction of the chloride with sodium, even in a vessel of pure boron nitride electrically heated by a resistance spiral of boron and boron carbide, yields only a black powder which will not weld to a compact mass. Iron is found to give the best results. Wire, prepared by drawing down Kahlbaum's pure iron, is wound on a frame made of boron nitride, and heated by means of a resistance tube of boron and boron carbide enclosed in a large glass vessel with mercury seals. The leading-in wires are of tungsten. After filling with hydrogen, the furnace is heated to redness to remove traces of oxygen. Hydrogen is then expelled by filling with boron trichloride. Most of the reduction takes place at about 800° C., and the temperature is then raised gradually to 1700° C. A porous mass of pure boron is thus obtained, which becomes denser on prolonged heating in boron trichloride. Compact boron thus prepared has an appreciable conductivity and is very infusible, an arc struck between boron poles showing no trace of fusion unless iron is present. The wires may be heated electrically to bright whiteness without injury.

Determination of the "explosibility" of pyrites as well as the available sulphur and the sulphur content of its cinders. Gyzander. See VII.

Course of the reaction between silver and sulphides. (Hepar test.) Hahn. See VII.

PATENTS.

Tool-steel; Alloy —. J. H. Parker, Reading, and B. H. de Long, Springmont, Pa., Assignors to Carpenter Steel Co., Reading, Pa. U.S. Pat. 1,233,118, July 10, 1917. Date of appl., June 26, 1916.

A TOOL-STEEL alloy is composed of approximately two parts of iron to one of cobalt, with 8 to 20% tungsten, 0.5% to 2.5% vanadium, and 1% to 6% of chromium.—T. H. B.

High-speed-tool-steel alloy. R. Furness, Jenkintown, Pa., Assignor to The Midvale Steel Co., Philadelphia, Pa. U.S. Pat. 1,233,862, July 17, 1917. Date of appl., Mar. 12, 1917.

A TOOL-STEEL alloy contains uranium 0.10% to 2.0%, cobalt 3% to 20%, tungsten 9% to 20%, and chromium 2% to 6%.—W. F. F.

[Iron ore briquettes;] Binding material [for], and the method of preparing —. W. Mathesius, Berlin. U.S. Pat. 1,233,384, July 17, 1917. Date of appl., May 21, 1915.

AN intimate mixture of finely-divided iron ore and dry slaked lime is heated to a temperature just below that of sintering, a further quantity of ore is added, and the mixture finely ground and moulded.—W. F. F.

Iron and steel; Process of manufacturing —. J. I. Bronn, Assignor to Rombacher Hüttenwerke, Rombach, Germany. U.S. Pat. 1,233,970, July 17, 1917. Date of appl., Apr. 24, 1917.

MOLTEN pig iron containing phosphorus is blown in a converter to oxidise and then remove the phosphorus. The slag is then removed and molten Thomas pig iron containing phosphorus is added in quantity slightly greater than that necessary to deoxidise the charge. The blowing is then renewed for a few seconds to oxidise the small amount of phosphorus present. —W. F. F.

Cementation process. F. A. Kaufmann, Perth Amboy, N.J., Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,235,901, Aug. 7, 1917. Date of appl., Aug. 11, 1915.

IRON and steel are carburised by the nascent carbon resulting from the decomposition of gaseous hydrocyanic acid at about 700° C., in the presence of the ammonia also produced. —T. H. B.

Tinning sheet metals; Method of —. C. Paetow and H. Lippmann, Berlin. Eng. Pat. 104,510, Mar. 1, 1917. Under Int. Conv., Feb. 26, 1916. (Appl. No. 3043 of 1917.)

SHEET metal is tinned on one face only by placing two sheets face to face and connecting them preferably at the edges by autogenous or electric soldering or welding, and then passing them through the tinning bath. The connected sheets may be left open at one side which is kept out of the bath during the tinning operation. —W. F. F.

Ores and other materials; Apparatus for treating —. H. B. Hovland, Duluth, Minn., U.S.A. Eng. Pat. 105,571, May 30, 1916. (Appl. No. 5174 of 1917.) Under Int. Conv., June 17, 1915.

IN an apparatus for successively sulphating and sulphidising ore-pulp and recovering the sulphides by flotation, the pulp is treated under pressure with sulphur dioxide and air, or with smelter smoke, etc., in a series of containers enclosed by a horizontal, cylindrical casing and provided with hollow, rotary agitators through which the gases are passed into the charge continuously. The sulphated charge emerging from the last container of the series is passed into a vertical conduit, the lower end of which communicates with the charging bin of the sulphidising unit, and the upper end with a closed receptacle having a bottom discharge outlet also connected with the bin; the arrangement being such that while the solid portion of the charge gravitates to the bin, the liquid portion is forced, by the pressure within the casing, into the closed receptacle above, and is therein treated with ferric sulphate (as a preliminary to the sulphide treatment) before readmixture with the solid material. —W. E. F. P.

Metal and other melting furnaces. I. Hall, Birmingham. Eng. Pat. 108,084, Oct. 31, 1916. (Appl. No. 15,504 of 1916.)

IN a furnace for melting metal or glass, heat treatment of residues, recovery of metals, etc., the lining of the extension of the crucible which forms a preheater comprises two annuli of different diameters integrally connected together. The annuli are composed of sections each having an outer and inner wall connected by radial ribs forming a combustion flue of quadrilateral cross-section. The sections are connected together by means of projecting tongues fitting into grooves in the adjoining sections. —W. F. F.

Converter bottoms, furnace hearths and the like for metallurgical purposes; Process for the manufacture of —. W. P. Thompson, London. From A. Bosshard, Zürich, Switzerland. Eng. Pat. 108,412, Nov. 16, 1916. (Appl. No. 16,399 of 1916.)

THE materials, preferably dolomite and coal tar, of which the bottoms, etc., are composed, are mixed and the mixture shaken into position instead of being rammed or stamped. —W. E. F. P.

Smelting furnaces. E. K. H. Lundberg, Bruzaholm, Sweden. Eng. Pat. 108,498, June 23, 1916. (Appl. No. 8871 of 1916.)

GAS is generated in the producer, 1, and passes by the openings, 18, controlled by dampers, 17, to the heating flues, 12, of the smelting chambers,

3. A regenerator is provided to heat the secondary air which meets the gas at the ignition point, 19. Receptacles, 7, are placed in the chambers, 3, in an unburnt condition, and are burnt previous to the smelting operation. Lateral openings are provided in the chambers, 3, for the introduction of metal and removal of dross, and a tapping hole, 8, is provided in each receptacle. The bottom of each smelting chamber is inclined and provided with a channel to conduct the molten metal away in the event of breakage of the receptacles, 7. Transverse flutes, 12a, are also provided in the flues to receive molten metal in the event of breakage of the chamber floor. —W. F. F.

Annealing ovens, [muffle furnaces,] and the like. A. McD. Duckham, Ashted, Surrey. Eng. Pat. 108,573, Sept. 25, 1916. (Appl. No. 13,587 of 1916.)

THE top of the muffle, 1, is traversed by cross flues, 2, leading from combustion chambers, 3, to vertical flues, 4, which communicate with

common longitudinal outlet flues, 5. Air enters the common chamber, 6, through openings, 7, and is heated by passing through the passages, 8, 9, 10, 12, to the combustion chambers, 3.

Producer gas passes down through vertical heated passages parallel to the passages, 10, and thence to the combustion chambers, 3. The combustion chambers, 3, alternate with the outlet flues, 4. The middle points of the cross flues, 2, are connected by passages, 15.—W. F. F.

Furnaces of the kind used for heating crucibles [for melting metals]. F. J. Grocott, Birmingham, Eng. Pat. 108,615, Nov. 21, 1916. (Appl. No. 16,831 of 1916.)

THE crucible is supported on firebars, and one of the bars at each side comprises an open-topped water channel extending outside the furnace, into which water drips to supply steam for the production of gas. Air is delivered to the ashpit through the front, and also if desired through parallel flues in the walls on each side opening into the sides of the ashpit. Steam may also be supplied through the latter flues to supplement the supply from the firebars. Additional heated air may be supplied through a flue which extends from the front wall of the furnace in a tortuous path round the ashpit and opens into the side walls of the heating chamber at points about midway of the height of the crucible.—W. F. F.

Furnace; Open-hearth —. T. S. Blair, jun., Chicago, Ill., Assignor to Blair Engineering Co., New York. U.S. Pat. 1,236,140, Aug. 7, 1917. Date of appl., Sept. 12, 1916.

IN an open-hearth furnace having a basic bottom, a gas port, and a gas down-take, a water-cooled bulkhead is provided in the upper end of the outer wall of the down-take, immediately below the entrance to the port, the bulkhead having an inclined surface to collect and retain slag particles.—W. E. F. P.

Zinc and other volatile metals; Method for extracting — from their ores, and apparatus therefor. F. Tharaldsen, Christiania, Norway. Eng. Pat. 108,363, Aug. 7, 1916. (Appl. No. 11,143 of 1916.)

ORES of zinc and other volatile metals are introduced into an electric radiation furnace in the form of a layer having a horizontal or slightly curved surface; volatile constituents are conducted through a separate outlet to a condenser. A movable table constitutes the bottom of the furnace; it is charged with the materials to be treated outside the furnace on one side, and the residue is removed outside the furnace on the other side. The surface of the charge is shaped by the lower edge of the wall of the furnace on the charging side, as the charge is passing into the furnace. The table is provided with side ribs and the walls of the furnace have projections overlapping the ribs to form tight joints, the charge serving as packing material.—T. H. B.

Recovering metalliferous minerals by flotation; Method of and means for —. G. Crerar, Spokane, Wash., Assignor to J. L. Boyle, Los Angeles, Cal. U.S. Pat. 1,232,772, July 10, 1917. Date of appl., Mar. 9, 1915. Renewed Nov. 27, 1916.

A MIXTURE of ore pulp and frothing agent is fed on to the upper end of an inclined, porous table the lower end of which terminates in a receptacle provided with a peripheral overflow for concentrate and a bottom discharge for tailing. During operation, air is forced through the table and produces a froth in the flowing pulp; the froth accumulates in the receptacle to a considerable depth and is therein subjected to the action of upward currents of air.—W. E. F. P.

Oil-flotation concentration process. E. Wagner, New York. U.S. Pat. 1,235,683, July 31, 1917. Date of appl., May 7, 1913.

A MIXTURE of ore pulp and oil is caused to ascend

in a vertical stream or column through which air bubbles of definite size are forced continuously and vertically from below. The concentrate is discharged by peripheral overflow at the top of the apparatus and the tailing at a point between the overflow and the air inlet.—W. E. F. P.

Ores; Flotation of —. R. F. Bacon, Pittsburgh, Pa., Assignor to Metals Research Co., New York. U.S. Pat. 1,235,954, Aug. 7, 1917. Date of appl., Jan. 4, 1916.

ORE containing metals forming acid-soluble and acid-insoluble sulphides is treated with hydrogen sulphide and sufficient acid to dissolve the constituents of the former class. The mixture is then subjected to flotation treatment to recover the acid-insoluble sulphides, and afterwards neutralised, treated with alkali sulphide, and re-treated by flotation to recover the acid-soluble sulphides. To effect separation of acid-insoluble sulphides from ore containing iron pyrites, the latter is subjected to a preliminary roast (to convert the pyrites into an acid-soluble form) before the application of acid and hydrogen sulphide.

—W. E. F. P.

Metals; Apparatus for electrolytically recovering —. G. A. James, Assignor to J. H. Alling and F. M. Wright, San Francisco, Cal. U.S. Pat. 1,233,363, July 17, 1917. Date of appl., Apr. 15, 1913. Renewed Oct. 14, 1916.

ELECTROLYTIC cells, used in series for the treatment of metalliferous pulp, are provided with insoluble anodes and mercury cathodes over which the pulp can flow in succession, means being provided for feeding an electrolyte with the pulp to the first of the series. A rotary reverser with four poles is arranged in the circuit, two of the poles being connected by a pair of conductors with the poles of the source of the supply, and the other two poles by a second pair of conductors with opposite sides of each of the cells. The reverser is so arranged that once in each rotation it successively connects electrically, during equal portions of time, each conductor of the first-named pair with conductors of the second-named pair. The current, thus automatically reversed, flows for a shorter period than the direct current, and means are further provided for automatically reducing the intensity of the reversed current.

—B. N.

[Molybdenum and vanadium;] Process of treating ores [containing —]. A. L. Pellegrin, Tucson, Ariz. U.S. Pat. 1,233,398, July 17, 1917. Date of appl., Nov. 13, 1916.

IN the separation of lead molybdate and vanadate from other lead minerals in complex lead ores, the ore is treated with a sulphidising material. The treatment is discontinued before the particles of molybdate and vanadate are attacked, and the attacked portion of the ore is then removed by flotation. The residue is subjected to similar sulphidising treatment until the molybdate is attacked but not the vanadate, and the two are then separated by flotation.—W. F. F.

Copper; Process of extracting — from oxidised ores. N. V. Hybinette, Christiania, Norway. U.S. Pat. 1,233,580, July 17, 1917. Date of appl., May 22, 1913.

A PORTION of the oxidised ore, containing iron which dissolves with the copper, is leached with sulphuric acid, and the solution is passed over a second portion of the ore which has been reduced by heating with carbonaceous matter at a low temperature. The ferric compounds are thus reduced to the ferrous condition, and the copper is then deposited electrolytically from the solution.

—B. N.

Copper-bearing substances; Method of treating ——. C. S. Bradley, New York. U.S. Pat. 1,236,046. Aug. 7, 1917. Date of appl., Dec. 9, 1911. Renewed Jan. 4, 1917.

THE copper is obtained in solution as cupric chloride, and then precipitated as the trioxycupride, which is subsequently converted into cupric oxide.—T. H. B.

Metal; [Electrolytic] process for coating ——. B. P. Allen, Great Neck Station, N.Y. U.S. Pat. 1,233,633, July 17, 1917. Date of appl., Feb. 19, 1917.

THE metal article is first immersed in a bath containing 80 c.c. of water, 10 c.c. of acetic acid, and 40 grains of lead chromate, and a current of electricity is passed through the article and the bath to produce a yellow deposit upon the article.—B. N.

Heat-treating apparatus; Continuous ——. T. F. Baily and F. T. Cope, Assignors to The Electric Furnace Co., Alliance, Ohio. U.S. Pat. 1,234,257, July 24, 1917. Date of appl., Feb. 3, 1917.

THE articles to be treated are passed through a heating furnace and then through a quenching bath to a reheating furnace. The means for moving the articles through the furnaces are controlled by the temperatures of the furnaces by means of a thermal device operating electric controlling means which are connected with the moving gear.—W. F. F.

[Manganiferous silver] ores; Process of treating refractory ——. S. J. Vermaes, Delft, Assignor to Mijnbouwmaatschappij Aequator, The Hague, Netherlands. U.S. Pat. 1,234,426, July 24, 1917. Date of appl., Aug. 7, 1916.

SILVER ore containing manganese dioxide is mixed with a reducing agent and a chlorinating agent, and the mixture roasted at a temperature insufficient to volatilise silver chloride. The product is then leached with cyanide solution.—W. E. F. P.

Bearing metals; Process of making ——. W. H. Kelly, Los Angeles, Cal. U.S. Pat. 1,234,547, July 24, 1917. Date of appl., Dec. 26, 1914.

METALLIC lead in the molten condition is purified by the action of oxygen and hydrogen, and then mixed with commercially pure copper.—T. H. B.

Ore-pulverising ball-mill. H. Eggers, Denver, Colo. U.S. Pat. 1,235,449, July 31, 1917. Date of appl., Feb. 24, 1917.

A ROTATING horizontal cylindrical casing, provided with a metal lining and containing grinding balls, is supported on hollow trunnions communicating with the interior and forming an inlet and outlet for the ore. A pair of transverse partitions, with lots arranged concentrically, are mounted near the outlet end of the casing, spaced apart by lugs and bearing against a flange on the casing projecting inwards. The perforated partitions are maintained in position by a hood forming the end of the casing and containing the hollow trunnion. The outer partition is also provided with a central rooved projection extending to the entrance of the hollow trunnion. The space between the partitions is partly filled with small hard metal grinding balls which are inserted through openings in the casing provided with screwed plugs. The ore thus passes through the main grinding chamber provided with balls of varying sizes, and then through the supplementary grinding chamber between the perforated partitions containing smaller balls, to the outlet.—W. F. F.

[Welding] uniting metals; Apparatus for ——. A. K. Sloan, Brooklyn, N.Y. U.S. Pat. 1,235,608, Aug. 7, 1917. Date of appl., Dec. 5, 1913.

A CARTRIDGE for welding copper wires comprises a cylinder having an insulating lining and containing the welding compound. The wires are inserted through opposite ends of the cartridge but are separated by a thin web of non-conducting material, so that when a current is passed through, an arc is formed which ignites the welding material. The material contains copper which melts and unites the two wires, and a gas absorbent is provided at the outer ends of the cartridge.—W. F. F.

Alloys; Process of treating ——. H. E. Cleaves, Washington, D.C. U.S. Pat. 1,235,655, Aug. 7, 1917. Date of appl., May 23, 1917.

IRON is removed from ferrotungsten containing more tungsten than iron, or from ferrovanadium or ferromolybdenum, by subjecting the alloy, in a finely divided condition, at a high temperature (1000° to 1100° C., for ferrotungsten), to the action of hydrogen chloride, iron chloride being formed and volatilised.—T. H. B.

Alloying metals; Process of ——. C. C. Baldwin, Perth Amboy, N.J., Assignor to Standard Underground Cable Co., Pittsburgh, Pa. U.S. Pat. 1,235,872, Aug. 7, 1917. Date of appl., Aug. 4, 1916.

COPPER is melted, and a specific quantity of it is added to a specific quantity of solid alloying metal, such as lead, zinc, and tin. A specific quantity of a suitable deoxidising agent is added to the copper, with which it is thoroughly mixed before coming in contact with the alloying metal.—T. H. B.

Gold-separator [amalgamator]. B. P. Tuggle, Portland, Oreg., Assignor to Redemption Gold Co., Seattle, Wash. U.S. Pat. 1,235,945, Aug. 7, 1917. Date of appl., Feb. 24, 1916.

A NUMBER of concentric vertical cylindrical containers are mounted on a frame so that they can be rapidly rotated. A concentric feed pipe is divided into as many longitudinal passages as there are containers, each passage communicating with one of the annular chambers. Pulverised ore suspended in water is fed by the central pipe to the annular separating chambers, and the particles are projected by centrifugal force on to the outer walls of the chambers, which are coated with mercury. Series of rings are provided upon the inner and outer walls of the separating chambers, the outer rings having apertures through them parallel to the axis of rotation, so that the layer of mercury is maintained at a predetermined and uniform thickness. The upper ends of the containers are maintained concentric by a number of glands, each of which has an annular overflow chamber connected by ports to the separating chambers.—W. F. F.

Metals [manganese, zinc, lead] from ores and the like; Process for the recovery of ——. C. S. Vadner, Humboldt County, via Battle Mountain, Nev. U.S. Pat. 1,236,236, Aug. 7, 1917. Date of appl., Nov. 27, 1916.

THE ore is treated with sulphur dioxide (roaster gases) in the presence of water, and the solution nearly neutralised and then oxidised by being passed over manganese dioxide or ore containing it, whereby lead and iron are precipitated. The liquid is then treated with a metallic oxide and chlorine to precipitate the manganese as peroxide in a slightly acid solution, the precipitate being filtered off and the filtrate treated for the recovery of zinc by known methods. Lead is recovered from the manganese-ore residue by leaching with a solution of sodium chloride.—W. E. F. P.

Tungsten or molybdenum; Process of coating — with noble metals. F. A. Fahrenwald, Cleveland, Ohio. Dedicated to the Government and people of U.S.A. (Dedicated to the public.) U.S. Pat. 1,236,383, Aug. 7, 1917. Date of appl., May 31, 1916.

AN oxidisable metal, such as tungsten or molybdenum, is heated in contact with an oxygen-containing alkali salt to which is added the haloid salt or salts of the coating metal desired. The process may be applied to the soldering or brazing of tungsten or molybdenum.—T. H. B.

Tungsten and molybdenum; Alloy of —. F. A. Fahrenwald, Cleveland, Ohio. Dedicated to the Government and people of the U.S.A. (Dedicated to the public.) U.S. Pat. 1,236,384, Aug. 7, 1917. Date of appl., June 3, 1916.

A FINELY powdered mixture of tungsten and molybdenum in the desired proportions is compacted under great pressure, and sintered, according to the proportions, for from ten minutes at 2600° C. for tungsten, and at 2300° C. for one minute for molybdenum. The mass is forged at about 1700° C. for an alloy of equal parts, downwards to about 1300° C. for tungsten or about 1000° C. for molybdenum, and is finally cold-worked.—T. H. B.

Ores and other materials; Apparatus for treating — under pressure. H. B. Hovland, Duluth, Minn., U.S.A. Eng. Pat. 100,545, May 29, 1916. (Appl. No. 7601 of 1916.) Under Int. Conv., May 27, 1915.

SEE U.S. Pat. 1,164,187 of 1915; this J., 1916, 185. A subterranean cavity may be used as the pressure-withstanding enclosure.

Ores and other materials; Apparatus for treating —. H. B. Hovland, Duluth, Minn., U.S.A. Eng. Pat. 100,681, May 30, 1916. (Appl. No. 7661 of 1916.) Under Int. Conv., June 17, 1915.

SEE U.S. Pat. 1,164,189 of 1915; this J., 1916, 185.

Smelling process [with wet-carbonised peat]. N. Testrup, London, and T. Rigby, Dumfries, Assignors to Wetcarbonizing, Ltd., London. U.S. Pat. 1,233,144, July 10, 1917. Date of appl., Feb. 9, 1914.

SEE Eng. Pat. 27,150 of 1911; this J., 1913, 93.

Aluminium or aluminium alloys; Soldering of —. W. Overend, Finsbury Park, Assignor to Overend Aluminium Soldering Processes, Ltd., Auckland, N.Z. U.S. Pat. 1,233,803, July 17, 1917. Date of appl., Apr. 24, 1916.

SEE Eng. Pat. 17,118 of 1915; this J., 1916, 1161.

Ore concentration. G. A. Chapman, Anaconda, Mont., Assignor to Minerals Separation North American Corporation. U.S. Pat. 1,234,288, July 24, 1917. Date of appl., Sept. 30, 1914. Renewed June 20, 1917.

SEE Eng. Pat. 17,327 of 1914; this J., 1915, 910.

Ores; Concentration of —. A. H. Higgins, London, Assignor to Minerals Separation North American Corporation. U.S. Pats. (A) 1,236,933 and (B) 1,236,934, Aug. 11, 1917. Date of appl., Sept. 23, 1914. (A) Renewed June 2, 1916.

SEE Eng. Pat. 1368 of 1914; this J., 1915, 233.

Electric smelling furnaces; Cooled bottom electrode for —. M. Sperling, Assignor to F. Krupp A.-G., Essen, Germany. U.S. Pat. 1,231,917, July 31, 1917. Date of appl., Nov. 13, 1911.

SEE Eng. Pat. 6731 of 1914; this J., 1914, 869.

Ores; Method for treating roasted — with liquids. A. Ramén, Olympia, Sweden. U.S. Pat. 1,235,598, Aug. 7, 1917. Date of appl., Mar. 4, 1915.

SEE Eng. Pat. 15,254 of 1914; this J., 1915, 838.

Zinc, copper, or other metals; Apparatus for production of — by electrolysis. M. Perreux-Lloyd, Boulogne-sur-Seine, Assignor to M. V. Bailly, Paris. U.S. Pat. 1,235,723, Aug. 7, 1917. Date of appl., May 24, 1915.

SEE Fr. Pat. 472,764 of 1914; this J., 1915, 497.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Furnace; Electric —. I. Rennerfelt, Djursholm, Sweden. Eng. Pat. 101,412, Sept. 1, 1916. Under Int. Conv., Sept. 8, 1915. (Appl. No. 12,396 of 1916.)

A FURNACE, of the type in which the heating is by the combined effect of arcs and resistances, is divided into two or several chambers, one of which is the arc chamber for the generation of heat, and the others are adapted for receiving the material to be treated. The latter chamber, or chambers, are partially or wholly surrounded or covered by a refractory resistance, which serves for receiving the arcs from the electrodes in the electric arc chamber, and also for conducting the heat, generated by the arcs and in the resistance, to the furnace or retort chamber or chambers. Three electrodes, connected to a three-phase circuit, may be provided in the arc chamber, each of which generates an arc contacting with a resistance, preferably finely-divided, or three or four electrodes may be connected to a two-phase circuit. In an alternative form, one or several electrodes may be provided in a chamber for electric arcs, and an electrode or contact may be embedded in a resistance beneath the arc chamber. Several cupel furnaces may be arranged above or adjacent one another in the resistance.—B. N.

Ozonisers. W. S. Graft-Baker, London. Eng. Pat. 108,293, Apr. 26, 1917. (Appl. No. 5929 of 1917.)

THE ozoniser comprises a frame, formed from side plates held together by transverse rods; other rods for supporting the metal ozonising plates are supported at their ends by resting on battens on the inner faces of the side plates. Two sets of

supporting rods are arranged at the top and bottom respectively of the frame, and the rods pass through perforations in the top and bottom respectively of the two sets of ozonising plates. The metal plates are provided with spacing-projections embossed thereon, and the projections of one plate are arranged in register with the recessed side of the corresponding projections of the next plate, so that the plates at all parts are equidistant from each other. The dielectric plates, which may or may not be supported from the rods, are placed between the plates, the embossed projections taking the place of insulators.—B. N.

Electrical contact members. H. V. S. Taylor, Pittsburgh, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pats. (A) 1,232,624 and (B) 1,232,625, July 10, 1917. Dates of appl., Jan. 21 and Aug. 30, 1916.

(A) A PAIR of make-and-break contact members is composed of two metals, one having a high melting point relatively to the other, such as a cathode of tungsten and an anode of silver. (B) The silver in (A) is replaced by a non-arcing metal, such as platinum.—W. F. F.

Electrical resistance element and process of making the same. M. H. Rice, New Rochelle, N.Y., Assignor to National Electric Utilities Corporation, New York. U.S. Pat. 1,232,843, July 10, 1917. Date of appl., Apr. 8, 1913.

AN electrical resistance element is made by coating a carbon base with a mixture of water glass, 1 part, clay, 2 parts, and graphite, 5 parts, and then heating to fuse the coating to the base.—W. F. F.

Insulation; Electrical.—. Electrical insulating composition and process of making the same. W. H. Steinberg, Assignor to The Cutler-Hammer Mfg. Co., Milwaukee, Wis. U.S. Pats. (A) 1,233,415 and (B) 1,233,416, July 17, 1917. Dates of appl., (A) Mar. 1, and (B) Aug. 23, 1915.

(A) A BINDER, for cementing purposes, is composed of approximately equal parts of coal tar pitch and stearin pitch, with a solvent comprising a volatile oil and a non-volatile oil, such as castor oil. (B) An electrical insulating composition is formed from a base of finely-divided asbestos and sulphur, which is mixed with a binder. The latter is formed by the action of heat upon a mixture of coal tar pitch, stearin pitch, and an oil capable of vulcanisation or polymerisation, mixed with a volatile solvent.—B. N.

Insulated wires; Method of making —. Sheathed heater-wire and method of making same. R. H. Read, Washington, D.C., Assignor to General Electric Co. U.S. Pats. (A) 1,233,807 and (B) 1,233,808, July 17, 1917. Dates of appl., (A) Jan. 3, 1914, and (B) July 30, 1914. (B) Renewed June 9, 1917.

(A) FIREPROOF armoured conductors, for electric heating or for transmitting devices which become hot when used, are prepared by covering a core wire with a medium formed from an insulating powder, refractory to heat, and a destructible organic binder containing a low percentage of a fusible binder. The medium is shrunk and the binder destroyed by heat, whilst finally, at a red heat, an infusible compound is formed. The medium is then enclosed in a seamless metallic armour, which is hammered by radial blows, so as to crush the medium to fine powder, and simultaneously make it compact on the core. (B) The conductor is surrounded by a bed of asbestos, and finely powdered mineral insulation is introduced into the pores of the asbestos. The asbestos-covered wire is led through rotating semi-circular walls, in which molten metal is supplied, and the walls are chilled continuously whilst the conductor

passes, thereby solidifying a seamless metallic sheath around the conductor. A terminal joint is arranged within the insulation, consisting of a metal tube, mechanically interlocked with the conductor and a good conducting lead wire, whilst a metallic cap of good heat-radiating capacity surrounds the joint and is secured to the sheath.—B. N.

Refractory substances; Method and apparatus for electrically reducing [melting] —. J. G. Webb, Richmond, Va. U.S. Pat. 1,231,836, July 31, 1917. Date of appl., Mar. 16, 1917.

THE charge to be melted is contained in a crucible provided with a number of electrodes converging downward toward the centre. Craters are formed by an electric arc between each electrode and the material, and are made to coalesce as the material melts, by advancing the electrodes inward. The angle between the electrodes is less than the angle between any electrode and the wall of the crater, so that contact with the material is avoided as the electrodes are moved forward.—W. F. F.

Electrical heating apparatus and process of making the same. S. Trood, Wilkesburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co., U.S. Pat. 1,234,973, July 31, 1917. Date of appl., Jan. 7, 1914.

A RESISTANCE unit for an electric heater is made by embedding a conductor, e.g., tungsten, between layers of insulating material, e.g., silica. An electric current is then passed through the conductor till the silica is partly fused, the melting point of the conductor being above that of the insulating medium.—W. F. F.

Electro-osmotic process of treating liquid mixtures. B. Schwerin, Assignor to Electro-Omose A.-G. (Graf Schwerin Ges.), Frankfurt, Germany. U.S. Pat. 1,235,063, July 31, 1917. Date of appl., Feb. 16, 1915.

XII.—FATS; OILS; WAXES.

African palm oil industry. III. Machinery. Bull. Imp. Inst., 1917, 15, 57—78.

AN account of the distribution, varieties, and method of preparing the oil and kernels has already been given (this J., 1910, 287; 1913, 797). The original difficulty of obtaining a yield of "soft" oil, i.e., oil of comparatively low acid value, has now been surmounted by a process of rendering the enzymes or micro-organisms inactive by heat and rapidly expressing and purifying the oil. The inferiority of "hard" oils containing a high percentage of free fatty acids and lower glycerin content is shown by the relative prices of hard and soft oils at normal times, viz., Lagos (soft) oil £31 per ton, Congo (hard) oil £26 per ton. It is stated that none but the soft or neutral palm oil containing less than 1% of dirt and moisture and not more than 8% of free acid can be employed in the manufacture of edible fat. A fairly detailed account of the plant employed in the several processes of working up the fruit of the oil palm, together with names of manufacturers of the same, yields, etc., is given. In the hand-power plant the oil is extracted by boiling with hot water under agitation; yields of 15.75% to 16.25% on fruit containing 22% of oil are obtained. The power-driven machines deal with the removal of fruit from bunches, separation of pulp, shelling, etc.

In these the oil is extracted by pressure in hydraulic presses, with or without previous removal of the nut. The kernel is removed from the nut by cracking the latter by centrifugal force against the walls of the centrifugal. A power-driven machine is described giving a yield of 20% of oil of sufficient purity to realise £2 per ton more than palm oil obtained in the usual way. It is concluded that development of the oil palm in the British Colonies and Protectorates will take place along the lines of establishment of a central factory situated in a centre where considerable planting will be necessary, thus diverting the native labour from individual extracting to the requirements of the factory. Such a system will necessitate the putting down of heavy power-driven plant, the hand-driven portable plant being more fitted to working up the fruits *in situ* over sparsely planted districts.

—A. DE W.

Manketti nuts from South West Africa. Bull. Imp. Inst., 1917, 15, 35—38.

MANKETTI or munkuetti nuts are obtained from the euphorbiaceous tree (*Ricinodendron Raudaninii*, Schinz.) found in the South African veldt. The sample examined consisted of fruits $\frac{3}{4}$ in. to 1 in. in diameter and 1 in. to $1\frac{1}{2}$ in. in length, composed of husks (13%), mesocarp (20%), and nuts (67%). The kernel of the nut formed about 10% of the entire fruit. The kernels contained 4.1% of moisture and 57.2% of a bright yellow liquid oil giving the following values: Sp. gr. at 15° C. 15° C., 0.9281; acid value, 1.9; saponification value, 191.5; iodine value, 133.6. From a consideration of its iodine value, insolubility in alcohol, and solubility in light petroleum, it is concluded that the oil belongs to the semi-drying oil group and not, as previously supposed, to that of castor oil. It is not considered to be particularly suited for use in paint or varnish manufacture, whilst many cheap vegetable oils are already available for the manufacture of soft soap. Its suitability as an edible oil has been shown by experiments of some German investigators a few years ago. Examination of the pulpy mesocarp of the fruit showed it to possess only a moderate percentage of proteins. In view of the small proportion of kernel and difficulty of extraction of the oil therefrom, it is considered that the exportation of the nuts to Europe would not be remunerative.—A. DE W.

Human adipocere. R. F. Ruttan. Trans. Roy. Soc. Canada, 1917, [iii.], 10, 169—170. J. Chem. Soc., 1917, 112, i., 495. (Compare Ruttan and Marshall, this J., 1916, 477.)

THE author has analysed specimens of adipocere of human origin, some of which were dry and firm and others soft and oily. The latter consist of immature adipocere and differ from the waxy variety in containing more oleic acid, proteins (soft connective-tissue and hyaline muscular fibres), and calcium soaps. Human adipocere, whether mature or immature, shows a remarkable similarity in composition to the adipocere from the pig. It is essentially composed of saturated fatty acids, glycerides being present in traces only. The two isomeric monohydroxystearic acids derived from oleic acid are invariably present, and the disappearance of unaltered oleic acid marks the final stage in the formation of mature adipocere. Adipocere is regarded as the product of the hydrolysis of fats by water where the time factor and the concentration of the reacting water are almost indefinitely great and where the soluble product, glycerol, is rapidly removed. Bacterial and enzymic actions play a quite secondary part in the production of adipocere. The hard, waxy character of the mature substance is largely due to the presence of the two hydroxystearic acids.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Burmese black varnish or lacquer. II. Bull. Imp. Inst., 1917, 15, 42—46. (See also Sing, this J., 1909, 993.)

AN earlier article (Bull. Imp. Inst., 1910, 8, 273) described the preparation and characteristics of Burmese lacquer together with the manufacture of Burmese lacquer ware. The present article gives the results of inquiries instituted at the request of the Forest Department in India to induce users of varnishes in this country to experiment with the material with a view to utilisation in European industries. Burmese lacquer is similar to Chinese lacquer and is likewise used in a liquid state as a varnish for woodwork and for waterproofing paper and cloth. Mixed with pigments as a decorative paint, or with ashes or teak sawdust it is used as a putty basis on woodwork or basket ware preparatory to application of finishing coats of the varnish. It is also used as a cement for glass mosaics in Buddhist temples. Figures are given showing the yield and value of "thitsi" (its native name) from different Forest Circles in Burma. Samples of three grades sent to the Imperial Institute for examination showed that the grading was dependent on moisture content only, the dried product being identical in each case. After application the varnish becomes hard in three days at 30°—35° C. in an atmosphere saturated with moisture, but remains sticky for several days when exposed in dry air at the normal temperature. In submitting samples of thitsi for trial to varnish chemists, manu-

facturers, and firms specialising in lacquer ware, reports on the material were obtained from which the following may be summarised; "Thitsi" appears to be quite equal to Chinese lacquer, although slower drying. It shows advantages over Japanese lacquer, but owing to the conditions required for its hardening, it does not seem to find favour as a substitute for other materials drying more quickly at ordinary temperatures. In view, however, of its special resistance to chemical and physical influences and its great elasticity, it would appear desirable, according to one report, to ascertain if the disadvantages accruing from the special conditions required for hardening it could be overcome without much difficulty. There appears to be little prospect of thitsi being exported extensively for use in Europe, but there should be a large demand for articles lacquered with the material locally.—A. DE W.

Tanning agents. G. Calvert, London. Eng. Pat. 108,262, Nov. 28, 1916. (Appl. No. 17,052 of 1916.)

A TANNING agent for use either alone or as an accelerator in conjunction with natural tanning agents, is obtained by the interaction of a phenolic body and formaldehyde in the presence of a saponaceous solution. For example, dried soap (1 lb.) is dissolved in water (1 lb.), and phenol or a phenolic body (1 lb.) and 40% formaldehyde (1 lb.) are added to the cold soap solution. The stock, or diluted stock, may be used alone, or may be added to, e.g., standard oak bark extract in the proportion 1:9. Softening or delining agents such as alkali sulphates or sulphides, or a weak acid, such as boric acid, may be added.—E. W. L.

Tanning. E. Stiasny, Leeds, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,232,620, July 10, 1917. Date of appl. Dec. 13, 1912.

SEE Fr. Pat. 443,730 of 1912; this J., 1912, 1015. The tanning agent is a compound containing at least one hydroxyl group in the molecule, but not more than one hydroxyl group in each nucleus.

Tanning: Apparatus for ——. A. Vandenweghe, New York, and A. D. Huyvetters, Ridgefield Park, N.J., Assignors to Ideal Cooney Dressing and Dyeing Co., Inc., Paterson, N.J. U.S. Pat. 1,233,730, July 17, 1917. Date of appl., Jan. 5, 1917.

THE hides or other materials are treated with tanning liquor in an upper series of vats, from which the liquor can be run off into a lower series in which it can be heated and then returned to the upper series. Means are provided for the introduction of trolleys or other devices beneath the upper vats and above the lower, in order to receive the tanned materials through outlets in the bottoms of the vats.—E. W. L.

XVI.—SOILS; FERTILISERS.

Soil flora studies. F. Actinomyces in soil. H. J. Conn. Tech. Bull. No. 60. New York Agric. Exper. Stat., March, 1917, 25 pages. (See also this J., 1917, 971.)

THE third large group of soil micro-organisms comprises the actinomyces, which, as a rule, form from 12 to 50% of the colonies on plate cultures made from the soil. About 70 different types of these organisms were found in the soils examined, three being of fairly common occurrence. One of these, hitherto undescribed, has been termed *A. pleochromogenus*. It is characterised by forming thick white mycelia and producing a deep brown pigment, which colours both the growth itself and the culture medium. One of the other two types has the same cultural characters as the potato scab organism, although it has not yet been proved to be pathogenic, whilst the third common type, which produces pink spores, is probably not a distinct species. The development of actinomyces in plate cultivations was not appreciably affected by the addition of manure to the soil, but the number of colonies tended to increase the longer grass was grown on the soil. Mixing dead grass roots with the soil had a similar stimulating influence upon the growth, but it could not be proved definitely that actinomyces played a part in the decomposition of grass roots in the soil.

—C. A. M.

Parahydroxybenzoic acid from soil; Isolation of ——. E. H. Walters. J. Amer. Chem. Soc., 1917, 39, 1778—1784.

IN an investigation of a sandy soil from Florida, 23 kilos. was extracted with 75 litres of dilute caustic soda at ordinary temperature for 24 hrs.,

the extract acidified and filtered, and the filtrate extracted with ether. The ethereal extract was purified and evaporated on the surface of warm water. When the water cooled, a crystalline compound separated, which was recrystallised from water and distilled with steam. From the distillate and residue crystalline substances were obtained; that from the residue amounted to 0.5 gm. and proved to be identical with *p*-hydroxybenzoic acid, while that from the distillate amounted to 40 mgrms. and was identified as benzoic acid.

—J. H. J.

Ammonia in the soil and in liquid manure; Determination of ——. W. I. Baragiola and O. Schuppli. Landw. Versuchs-Stat., 1917, 90, 123—137. J. Chem. Soc., 1917, 112, ii., 380—382.

THE ammonia present in the soil may be estimated as follows: 50—100 grms. of the soil is mixed with 5—7 grms. of magnesia, and at once introduced into a (Claisen) (two-necked) fractionating flask holding about three-quarters of a litre, together with about 100 c.c. of water. The flask is connected with a bulb tube passing tightly through the stopper of a pump flask which contains 10—20 c.c. of *N*/5-sulphuric acid, and is surrounded by ice-water. The side-tube of the pump flask is connected with that of a second, which serves as a safety flask, and is joined to a water-pump and also carries a manometer. A tube, drawn out at the bottom to a capillary and connected above with a sulphuric acid washing bottle, passes almost to the bottom of the distillation flask. The pressure is lowered to about 15 mm. and the water-bath in which the distillation flask is immersed is heated to about 35° C. The distillation is continued until the residue is dry, this requiring about two hours. A slow current of ammonia-free air is then passed for a time through the flask. The contents of the receiver are finally washed out into an Erlenmeyer flask, boiled to expel carbon dioxide, and when cold titrated with *N*/10-sodium hydroxide in presence of Congo-red; the titration is carried on until the colour matches that given by a mixture of the same volume of *N*/5-sulphuric acid as is used in the test with an equivalent volume of *N*/10-sodium hydroxide. Under the above conditions, not only ammonia, but also volatile amines and other bases, may pass over, and details are given of the separation of ammonia from the distillate as magnesium ammonium phosphate. Direct titration of the distillate obtained as above and that from the magnesium ammonium phosphate, however, gives virtually identical values, so that amines and volatile bases other than ammonia pass over only in negligible quantity. The ammonia which passes over when soil is distilled with magnesia seems to be that actually existing as ammonium salts in the soil, since after some time it disappears, having undergone complete conversion into nitrate.

The above method is applicable also to liquid manure, 50 c.c. of the latter and 10 grms. of magnesia being taken, and the distillate made up to a definite volume and aliquot portions used for the direct titration of the volatile basic nitrogen and for the precipitation of the ammonia as magnesium ammonium phosphate.

Manure treated with sulphur and sulphates; Fermentation of ——. Changes in nitrogen and phosphorus content. J. W. Ames and T. E. Richmond. Soil Sci., 1917, 4, 79—89.

THE loss of dry substance from manure (horse manure and fine straw litter) after fermenting for 250 days was 32.5% in untreated manure and 21.8% from manures treated with acid phosphate (342 grms. per 30 lb.) and calcium sulphate (407 grms. per 30 lb.), whilst manure treated with sulphur (90 grms. per 30 lb.) lost 18%. Manures

treated with acid phosphate (superphosphate), calcium sulphate, or sulphur lost 3.5% of their total nitrogen, and untreated manure lost 10.5%. The water-soluble and citrate-soluble phosphoric acid decreased in all the samples of manure. During fermentation the manure treated with sulphur increased in acidity whilst the untreated manure became alkaline. Sulphur, calcium sulphate, and acid phosphate were very effective in preventing loss of nitrogen from urine. In about 5 weeks untreated urine lost 80% of its total nitrogen; that treated with sulphur, 10%, with calcium sulphate, 9.7%, whilst the urine treated with acid phosphate lost only 5% of its nitrogen. —W. P. S.

Nitrogen fixation; Relation of green manures to —. H. L. Fuhrer. *Soil Sci.*, 1917, 4, 1—17.

GREEN manures, such as clover, wheat, or oats, when added to soil favour the fixation of free nitrogen; the gain in nitrogen content appears to be greatest in field soils, probably due to the presence of a greater number of nitrogen-fixing organisms. The non-legume tissue stimulates the fixation more than does the legume, possibly because of the nature of its carbohydrate content. The plants (non-legume) giving the best results are the lowest in nitrogen-content. —W. P. S.

Crop yield: Influence of the fineness of division of pulverised limestone on — as well as the chemical and bacteriological factors in soil-fertility. N. Kopeloff. *Soil Sci.*, 1917, 4, 19—71.

AN increase in the fineness of division of powdered limestone, added to soil, from 20- to 40-mesh, 60- to 80-mesh, 100- to 200-mesh, to finer than 200-mesh produces a proportional increase in the yield and total nitrogen content of crimson clover on several types of soil. The finer the division of the limestone the more rapid is the neutralisation of the soil acidity and the greater the increase in the activity of the bacteriological processes of ammonification, nitrification, and nitrogen-fixation. In the case of barley, buckwheat, and rape, fine limestone without supplementary addition of nitrogen fertilisers, gives as high a yield as coarse limestone with an application of 600 lb. of ammonium sulphate per acre; 200-mesh limestone may be regarded as being as effective as burnt lime. —W. P. S.

Soya beans; Yield and nitrogen content of — as influenced by lime. J. G. Lipman and A. W. Blair. *Soil Sci.*, 1917, 4, 71—77.

LIMING the soil increases the yield of soya beans and also the nitrogen content of the beans. When the crop is harvested as hay or as dry stalks, the yield and nitrogen content are also greater on limed soil. An acre of limed soil yielded an average of 19.3 bushels of beans containing 6.15% of nitrogen, whilst an acre of unlimed soil yielded 13.2 bushels of beans with 5.73% of nitrogen. —W. P. S.

Iron: Use of — in agriculture. A. Monmer and L. Kuczyaski. *Arch. Sci. phys. et nat.*, Geneva, 1917, 43, 66—68. *Bull. Agr. Intell.*, 1917, 8, 693—694.

SOME years ago the authors and Chodat found that plant growth was favourably affected by applying to the soil a dilute solution of a ferric salt at the beginning of vegetation, but application at a later stage had no such effect. It is now shown that the iron present in soils of normal composition is in a form very difficult to assimilate, being insoluble in water and dilute alkalis though slightly soluble in some dilute acids, e.g., 1% citric acid. Certain silicious soils entirely lacking in lime contain a considerable amount of water-soluble iron, and in such a soil pink hydrangeas give blue flowers;

but if a small quantity of calcium carbonate or magnesia is mixed with the soil the iron becomes insoluble and pink flowers are produced. When a dilute solution of an iron salt is filtered through soil of normal composition, the iron is completely precipitated as hydroxide or carbonate and retained by the superficial layers of soil, e.g., by the top 2 cm. if the soil contains about 5% of lime. Hence treatment with ferric solutions does not affect plants of which the roots have penetrated some distance into the soil. Potassium ferrocyanide applied in the same way to soils is not rendered insoluble, but part of the potash is retained by the soil and some oxidation to ferricyanide occurs. —J. H. L.

Illuminating gas: Action of — on plants. I. Action of the gas on the germination of spores and seeds. C. Wehmer. *Ber. Deut. bot. Ges.*, 1917, 35, 135—154. *J. Chem. Soc.*, 1917, 112, i., 507.

ILLUMINATING gas exhibits no general poisonous character towards plants. Anaerobic fungi grow even in the undiluted gas, and cross seeds (*Lepidium sativum*) remain alive in it for weeks. It retards the growth of the embryo, but this proceeds uninterrupted if the gas is diluted with about five times its volume of air. Gas is thus not an acute plant poison, but if it is passed for some time through soil, the latter becomes incapable of permitting seeds to germinate and grow in it; after such soil has been extracted with cold water, it behaves normally towards seeds, the injurious properties being transferred to the water. The principal constituents of coal-gas to which its action on plants is due are sulphur compounds, benzene and its homologues, and, to a less extent, ethylene. Carbon monoxide is without effect on plants.

PATENTS.

Peat for agricultural and horticultural purposes: Treating —. A. Nightingale, Bedford. Eng. Pat. 108,543, Aug. 18, 1916. (Appl. No. 11,708 of 1916.)

RAW peat, containing 50—70% of moisture, is mixed rapidly with 20% by weight of calcium oxide and the temperature of the mass allowed to rise to 220° F. (104° C.). The material is ready for use on cooling. —W. E. F. P.

Fertilisers from silicates; Process of producing —. L. L. Jackson, Assignor to O. C. Horney, New York. U.S. Pat. 1,232,553, July 10, 1917. Date of appl., June 16, 1916.

SILICATES containing alkali metals and aluminium are decomposed by heating with calcium hydroxide and water under pressure. The resulting mixture is filtered and the solution neutralised with acid and evaporated to dryness for the recovery of alkali salts. The residue is treated, first with sufficient acid to convert all the calcium present into a calcium salt, without dissolving the aluminium hydroxide, and then with sufficient acid to dissolve the latter, the two solutions being collected separately. The final insoluble residue is mixed with the dry alkali salts previously obtained to form a fertiliser. —W. E. F. P.

Dicalcium phosphate; Process of making —. W. Glaeser, Brooklyn, N.Y. U.S. Pat. 1,235,025, July 31, 1917. Date of appl., May 1, 1916.

PHOSPHATE rock is heated with hydrochloric acid and the solution treated, at about 30° C., with calcium hydroxide to precipitate amorphous dicalcium phosphate (soluble in ammonium citrate) which is filtered off and dried. —W. E. F. P.

Fertiliser composition. J. G. Lipman, New Brunswick, N.J. U.S. Pat. 1,235,906, Aug. 7, 1917. Date of appl., Sept. 6, 1916.

A MIXTURE of finely divided sulphur, 1; bacterially

active material capable of promoting the oxidation of sulphur, 1; and ground phosphate rock, 2—10 parts.—W. E. F. P.

XVII.—SUGARS ; STARCHES ; GUMS.

Clarification: Increase of the coefficient of purity caused by— in the cane sugar factory. 11. Pellet. Intern. Sugar J., 1917, 19, 367—368.

COMMENTING upon a statement that by merely liming and heating raw cane juice, an increase of 2.6 in the purity value had been produced, the author points out that the normal increase under the best possible conditions is about 1.8, and quite frequently is less. In carrying out the determination, it is important to free the juice from suspended matter, such as particles of bagasse and fine clay. An error may also be introduced by delaying the analysis of the sample representing the unclarified juice until that of the clarified product is available, since the former deteriorates very rapidly, much more so than the latter, the sucrose being converted to reducing sugars by invertase even in the presence of preservative substances as chloroform, salicylic acid, thymol, or formaldehyde. It has been stated that between the juice entering and that leaving the evaporators there occurs a loss of reducing sugars, but investigations on this point carried out by Geerligs in sugar factories in Java have conclusively proved this to be untrue, so that in fact there may be an increase in the syrup, even under proper working conditions.—J. P. O.

Date palm sugar industry; Some experiments on the improvement of the—. H. E. Annett. Agric. J. India, 1917, 12, 412—445.

IN India about 16% of the home-grown sugar is produced from palms, mostly from the wild date variety, *Phoenix sylvestris*, which is the common sugar palm of Bengal, and from the palmyra, the chief producer in Madras. Experiments conducted upon the best method of raw juice collection in earthenware pots showed that the Bengal method of previously smoking the pots over a fire has a distinct effect in preserving the juice. Formalin has a similar effect, but the results are very variable. The use of pots coated inside with lime is, however, by far the most satisfactory procedure, and is strongly to be recommended. Metal buckets, for an undetermined reason, give very unsatisfactory results. Hitherto the juice dripping from the trees during the day has fermented to such a degree as not to be worth working up for sugar, but the author has shown that if the practice of previously liming the pot be followed, excellent crystalline *gur* may be obtained from this juice, and the total yield per 24 hours may thus at the same time be increased at least 20%. Palm *gur* is appreciably darker than the native product from the cane, due to the fact that the juice being alkaline, black decomposition products of the reducing sugars, notably levulose, are formed during boiling; but this trouble is readily overcome by previously neutralising the juice, for example, with citric acid. Tests on evaporation in native furnaces showed that a considerable economy of fuel may be effected by the use of a number of pans, for example, four, with a good underdraught, in place of the single pans at present employed.—J. P. O.

Dextrose; Determination of—. G. Frerichs and E. Mannheim. Arch. Pharm., 1916, 254, 138—148. J. Chem. Soc., 1917, 112, ii., 393—394.

THE authors prefer Rupp and Lehmann's iodometric method of estimating reducing sugars to the

Fehling-Soxhlet method, and deny Ruoss's statement that the iodometric estimation of the excess of the cupric salt remaining after Fehling's solution has been partly reduced by a sugar solution yields untrustworthy results, owing to the action of oxidised sugar compounds on the liberated iodine. They find that the substances produced from the sugar by the action of the alkaline copper solution have no action on iodine. The table published by Rupp and Lehmann giving the number of mgrms. of dextrose corresponding with a given consumption of N/10-thiosulphate has been incorrectly calculated, and the authors give a list of corrected values. Details are given of the application of the method to the determination of dextrose in urine.

d-Galactose; o-Tolylhydrazine, a sensitive reagent for—. A. W. Van der Haar. Rec. Trav. Chim. Pays-Bas, 1917, 37, 108—110.

THE formation of the *o*-tolylhydrazone is a sensitive test for *d*-galactose, even in the presence of other monosaccharides. One part of *d*-galactose dissolved in one part of water is heated on the water-bath for half an hour with one part of *o*-tolylhydrazine dissolved in 20 parts of absolute alcohol. After 21 hours, the hydrazone is filtered, with the aid of the pump, washed with alcohol and ether, and recrystallised from 95% alcohol. It forms colourless shining needles which melt at 176° C. It is practically insoluble in cold water, slightly soluble in cold alcohol, more soluble in hot water or hot alcohol, and easily soluble in pyridine. 100 mgrms. of *d*-galactose can be detected in the presence of a mixture of 50 mgrms. each of arabinose, xylose, rhamnose, dextrose, mannose, and levulose, since none of these forms an *o*-tolylhydrazone.—F. Sr.

l-Arabinose and l-xylose; Method of oxidation and the oxidation products of— in alkaline solutions with air and with cupric hydroxide. J. U. Nef, O. F. Hedenburg, and J. W. E. Glattfeld. J. Amer. Chem. Soc., 1917, 39, 1638—1652. (See this J., 1908, 31; 1910, 1264; 1913, 366.)

BY aerating 50 grms of *l*-arabinose in dilute potassium hydroxide solution (5 equivalents) at 38°—41° C., and working up the products, the authors obtained 15.35 grms. of formic acid, 3.73 grms. of calcium glycolate, 14.12 grms. of *l*-erythronic- γ -lactone, and less than 1 gm. each of *d*-threonic phenylhydrazide, quinine-*l*-glycerate, and calcium *d*-glycerate. *l*-Xylose under similar conditions yielded 13.17 grms. of formic acid, 18.09 grms. of *l*-threonic phenylhydrazide, 4.94 grms. of calcium glycolate, and less than 1 gm. each of *d*-erythronic- γ -lactone and calcium *l*-glycerate. The two pentoses were also oxidised in alkaline solution, by cupric hydroxide, at 100° C., and small quantities of some of the products were isolated.—J. H. L.

Lactose, maltose, and sucrose; Action of formaldehyde on—. A. Heiduschka and H. Zirkel. Arch. Pharm., 1916, 254, 456—487. J. Chem. Soc., 1917, 112, i., 446—447.

IN view of the contradictory observations recorded in the literature of the action of formaldehyde on different kinds of sugars, the authors have examined the substances obtained from formaldehyde and lactose, maltose, or sucrose in aqueous solution. Formaldehyde and the bioses yield products the compositions of which vary with the relative proportions of the sugar and formaldehyde used in the preparation, and any one product does not differ in essential chemical characteristics from any other product or from its components. The products therefore are not to be regarded as definite chemical compounds. Products containing up to 39% of formaldehyde have been

prepared; from products containing a higher percentage paraformaldehyde separates. Products containing a high percentage of formaldehyde yield products containing a lower percentage by evaporating their aqueous solution in a vacuum. The capacity to take up formaldehyde is different in the three bioeses, being greatest in sucrose and least in maltose. The formaldehyde in the products can be estimated by the sulphite method and the sugar polarimetrically, the sum of the two percentages being 100.

Following the directions of Oppermann and Goehde (Eng. Pat. 6653 of 1897; this J., 1898, 263) and of Rosenberg (Eng. Pat. 2682 of 1906; this J., 1906, 1067) the authors have been unable to obtain from lactose and formaldehyde substances having the compositions recorded by these investigators. The products lose all their formaldehyde at 190° C. and leave pure lactose. The products are soluble in alcohol. This is noteworthy since lactose is practically insoluble in this solvent. The authors now find, however, that lactose is more soluble in alcohol containing formaldehyde than in alcohol alone, and that the products mentioned above are more soluble in alcohol the greater is their formaldehyde content; from such solutions lactose is deposited almost quantitatively as the formaldehyde progressively reacts with the solvent.

Other properties of sugar and formaldehyde solutions, such as the density and the viscosity, have been examined, and the authors are of opinion that the products obtained from formaldehyde and a bioese are solid solutions of formaldehyde in the sugar. The sugar takes up relatively more formaldehyde from dilute solutions of formaldehyde than from concentrated solutions.

Honey; Biological examination of—J. Gadammer and K. Laske. Arch. Pharm., 1916, 254, 306—345. J. Chem. Soc., 1917, 112, ii., 395—397.

ONE of the most difficult tasks of the food analyst is to prove the genuineness of bee-honey by chemical analysis, especially since solutions of very pure invert-sugar with or without raffinose, which can be used to adulterate natural honey or to prepare artificial honey, have become easily obtainable. Fiehe's reaction, which detects hydroxymethylfurfural in commercial invert-sugar, is not conclusive, and methods based on the estimation of the nitrogen and albumin in natural honey are easily evaded. Langer has shown that the honey albumin is quite independent of the plant visited by the bee, and the authors investigated the precipitin method of testing honey. Suitable anti-sera (0.2—0.5 c.c.), the preparation of which is described in detail, were mixed with 1 c.c. of 1—10% honey solutions, of 10% artificial honey solution, of 10% starch syrup solution, also 0.5 c.c. of normal dog serum was mixed with 1 c.c. of 10% honey solution; each mixture, after the addition of one drop of toluene, was vigorously shaken and kept at 37° C. for five hours, the tubes were centrifuged (1500 rev. per minute) for five minutes, and the volume of the precipitate (if any) read off in mm. It was found that: (1) Preservation of the liquid during the time of the experiment is unnecessary. The presence of toluene causes the formation of emulsions and renders a quantitative separation of the precipitate by centrifuging impossible. In the absence of toluene, quantitative results are obtained. (2) An absolute constancy in the activity of the precipitating serum cannot be claimed. Different anti-sera give approximately equal amounts of precipitate, and the variations are not so great as to render the method inapplicable for quantitative purposes. (3) With a given anti-serum, the amounts of precipitate obtained from 2% and 1% solutions of a honey are by no means comparable;

therefore, in examining a honey by the biological method, only the values obtained with a 10% solution should be utilised. (4) The amount of precipitate obtained from a given honey and the same anti-serum is the same during the period of one year. A specimen of genuine honey which had been kept for eleven years gave, however, only a very small precipitate. The authors are of opinion that the precipitin reaction has a real quantitative value. All honeys which fail to give a precipitate with honey albumin anti-serum are to be regarded as not genuine bee-honeys. If a precipitate is obtained and its amount corresponds with that obtained from the control honey, the honey under examination is genuine. If the amount of the precipitate is smaller than that given by the control, the honey under examination is either genuine honey which has been heated or honey which has been adulterated.

Formation of starch-like substances by moulds. Welmer. See XVIII.

PATENT.

[Sugar] cane juice; Process for clarification of —. D. B. Rogan, New Orleans, La. U.S. Pat. 1,233,919, July 17, 1917. Date of appl. Sept. 30, 1916.

EXCESS of lime is added to the juice, which is afterwards aerated, slightly acidified with sulphur dioxide or carbon dioxide, and again limed, this time almost to neutrality, all of these operations being conducted at a temperature not higher than 40° C. Finally, the treated juice is heated almost to 100° C.—J. P. O.

XVIII.—FERMENTATION INDUSTRIES.

Proteoclastic enzymes of yeast and their relationship to autolysis. K. G. Denby. Biochem. Zeits., 1917, 81, 109—208. J. Chem. Soc., 1917, 112, i., 500—501.

THE author has succeeded in demonstrating the presence in yeast of three proteoclastic enzymes, which are analogous to, but differ in certain particulars from, the proteoclastic enzymes of the animal organism. These enzymes are: I. Yeast pepsin, which can degrade genuine proteins to peptones (but not further). Its optimal action is in a medium of $pH=4-4.5$, whereas animal pepsin acts best in a medium of $pH=1.5$ (Sørensen). II. A yeast tryptase, which does not act on the proteins of yeast, but can degrade certain proteins, such as acid albumin, gelatin, caseinogen, into peptides and amino-acids. Its optimal action is in a medium of $pH=7$, as compared with that of $pH=8$ which is optimal for animal tryptase. III. A yeast creptase, which readily degrades peptones and polypeptides into amino-acids and has an optimal action in a medium of $pH=7.8$, which is very nearly the same as that of animal creptase. It differs, however, from the latter in that its action is not markedly inhibited by neutral salts, whereas that of the animal creptase is. A concentration of 0.5N-salt solution has little action on yeast creptase, whereas the animal creptase is inhibited by a concentration of 0.02N. The individual ions have apparently little action, as they act more or less alike, the diminution of the action of the enzyme being controlled by the salt molecules as a whole. The autolysis of yeast is due to the successive action of the various enzymes, and the maximal action takes place in a medium of $pH=6.0$. Deamidases play only a subordinate rôle in the autolysis. The method of investigation employed by the author consisted in following the course of degradation of yeast and other products in media with varying hydrogen-ion concentrations, both in the presence

and absence of buffer solutions. In the absence of such solutions, the hydron concentration changed during the course of the enzyme action. The chief indication as to the presence of various enzymes was afforded in this case by estimating the total nitrogen, amino-peptide, and protein nitrogen in solutions of the autolysis mixture after varying intervals of autolysis. When no buffer mixture was present, the total nitrogen and amino-nitrogen continually increased, especially towards the end, whereas the peptide nitrogen first increased and then diminished, and the protein nitrogen first diminished slightly and then increased slightly. The p_H changed during the reaction from 6.0 to 6.8. The results indicate that at the commencement the pepsin was chiefly active, whereas towards the end, in the more alkaline medium, the erepsin was most active. The detailed action of the various enzymes was also investigated, the enzymes being isolated by extracting them from yeast plasmolysed by chloroform in presence of calcium carbonate and submitting the extracts to dialysis against diminished pressure by a method recently described by Sørensen.

Emulsin-like enzymes separable from the cells of bottom yeast; Presence of — and the absence of myrosin in Berlin top and bottom yeast. C. Neuberg and E. Färber. *Biochem. Zeits.*, 1916, 78, 264—272. *J. Chem. Soc.*, 1917, 112, i, 501.

THE maceration juice of bottom yeast contains all three enzymes which act on amygdalin (amygdalase, prunase, and oxynitrilase). β -Glucosides are also hydrolysed by the maceration juice of Munich bottom yeast. The myrosin enzyme has been found neither in top nor bottom yeasts (free yeast and maceration juice of dried cells) of Berlin, and is also not present in dried Munich bottom yeast.

Lactic acid, acetic acid, and acetone; Use of sucrose-inverting bacteria for the manufacture of —. G. Mezzadrol. *Boll. Assoc. Ind. Zucch. e Alcool.* Bologna, 1917, 9, 142—145. *Bull. Agric. Intell.*, 1917, 8, 787—789.

IN experiments at the R. Stazione de Bieticoltura, Rovigo, on the direct production of lactic acid from beet-juice, certain bacteria capable of inverting sucrose before subjecting it to lactic fermentation have been isolated from sour milk and beet-juice. They are termed provisionally *Bacilli succaro-invertenti*, and subdivided into inverting lactic bacilli (*B. invertenti latici*), and inverting acetic bacilli (*B. invertenti-acetici*). Pure cultures of the former, grown in sterilised beet-juice containing 10% of sucrose, at 36°—38° C., yield per 100 parts of sucrose:—60—80 parts of lactic acid, 10—20 parts of acetic acid, 1—7 parts of alcohol, and traces of acetone and higher alcohols. The other sub-class, inverting acetic bacilli, produce a more rapid fermentation, with copious evolution of gas consisting of carbon dioxide, hydrogen, and small amounts of methane; yields of 40—50 parts of acetic acid, 10—20 parts of lactic acid, 10—20 parts of alcohol, and 1—2 parts of acetone have been obtained per 100 parts of sucrose, and it appears probable that acetic acid may soon be profitably produced directly from sugar. None of the organisms studied formed sufficient amounts of acetone to warrant industrial application for this purpose: lactic acid can be oxidised by hydrogen peroxide to acetic acid, and from the latter acetone can be produced more easily and at less cost than directly.—J. H. L.

Starch-like substances; Formation of — by moulds. F. Boas. *Biochem. Zeits.*, 1917, 81, 80—86. *J. Chem. Soc.*, 1917, 112, i, 503.

IN the presence of mineral acids, *Aspergillus niger*

can produce in the culture medium, from glycerol and mannitol, a substance giving the blue iodine reaction. It can also produce such a substance in fairly high concentrations from the following organic acids (the reaction being the most intense in the first-named acids) when they are used as the source of carbon in the medium: tartaric, citric, malic, succinic, and oxalic acids. The substance producing the iodine reaction tends to disappear after a certain interval.

Vinegar; Changes undergone by cider during fermentation, prolonged storage, and conversion into — in rotating generators. B. G. Hartman and L. M. Tolman. *J. Ind. Eng. Chem.*, 1917, 9, 759—762.

THE juice was expressed from New York apples as commonly used for the manufacture of vinegar, the yield being about 170 galls. per ton. It was allowed to ferment spontaneously, and yielded a wash containing 7.0% (by vol.) of alcohol. The average composition of the resulting vinegar was:—Total solids, 1.24; alcohol (by vol.), 0.25; ash, 0.32; acetic acid, 0.57%. The loss of acid during acetification was 17%, and there was a further loss of 1% during clarification and storing of the vinegar. The glycerin (0.23%) remained fairly constant throughout the process. During fermentation of the juice a large part of the malic acid (0.72%) was destroyed to form lactic acid, whilst the remainder was almost entirely oxidised during acetification. The fixed acid in the finished vinegar was mainly lactic acid (0.07%). The phosphoric acid (as P_2O_5) showed only a slight decrease during the fermentation, but fell by about 12% in the acetification. Pentosans, or their equivalent, increased by about 100% during acetification (to 0.08%). The vinegar contained traces of acetates and of formic acid.—C. A. M.

Oxidation and reduction; Biochemical phenomena of simultaneous —. Abelous and Aloy. *Comptes rend.*, 1917, 165, 270—272.

BACH has shown that milk contains an enzyme capable of reducing alkali nitrate to nitrite, but only when a substance capable of acting as a co-enzyme is present. According to Bach, such co-enzymes are aldehydes or substances yielding aldehydes on oxidation (see this J., 1911, 917). These aldehydes decompose water and are themselves oxidised, while the liberated hydrogen reduces nitrates or similar substances present. The authors have found that many other substances besides aldehydes may act as co-enzyme, e.g., amines, heterocyclic compounds, terpenes, and manganese salts. In one experiment, sodium fluoride, sodium chlorate, and salicylic aldehyde were added to milk which was then heated at 60° C. for 1 hr. out of contact with air, and afterwards incubated at 40° C. The chlorate was gradually reduced to chloride and the aldehyde oxidised to acid. Exothermic reactions also make endothermic reactions possible. For instance, the precipitate obtained from apple juice by addition of alcohol was dissolved in dilute sodium carbonate and filtered. The filtrate was divided into two parts: to both were added potassium chlorate, salicylic aldehyde, and sodium fluoride, while to one was added starch and amylase, and to the other, starch and boiled amylase. After 24 hours' incubation in absence of air, it was found that there was a large reduction of chlorate to chloride and a formation of salicylic acid in the solution containing the unheated amylase, while there was no change in the other solution. Probably in the living body, reactions of this character take place.

—J. H. J.

Pancreas; Composition and digestive activity of different fractions of the—. R. A. Nelson and J. H. Long. J. Amer. Chem. Soc., 1917, 39, 1766—1778.

FINELY minced pancreas can be separated into three layers in a centrifuge. The top layer contains fat, the middle layer is a liquid containing solids in suspension, and the bottom layer is a solid, mostly protein. The liquid layer yields a clear filtrate, containing phosphates and protein. The amylolytic activity resided in the middle layer, which was very active in the case of hog pancreas and only slightly so in the case of pancreas from the ox and sheep. The tryptic activity of the layers was determined by the amount of amino-acid produced from fibrin. All the layers showed tryptic digestion in the different pancreases, the top and bottom layers being especially active. The lipolytic activity was determined upon an olive oil emulsion, the free fatty acid formed being titrated after $\frac{1}{2}$, 1, and 2 hr. periods. Hog pancreas surpassed ox and sheep pancreases; the middle layer was nearly inactive in each case. The esterase activity was determined on a saturated solution of ethyl butyrate. The results were on the same lines as those for lipase; but in the hog pancreas the lipase was more active than the esterase, while in pancreas from the ox and sheep the esterase was the more active. This indicates that different enzymes are involved.—J. H. J.

XIXA.—FOODS.

Milk; Analysis of—. E. Ackermann. Ann. Chim. Analyt., 1917, 22, 152—158.

To distinguish between watered milk and abnormal milk, the author proposes to determine the percentage of lactose in the sample and to deduct this quantity from the percentage of non-fatty solids of the sample. In the case of normal milk the result obtained is always above 4. If the milk is abnormal, due to unhealthy condition of the cows, the result will still be above 4, but the quantity of lactose will be low. Addition of water decreases all the results correspondingly. Further work, however, is required before the usefulness of the method can be definitely established. The quantity of lactose may be calculated from the refraction of the milk serum and tables are given for this purpose.—W. P. S.

Fruits; Acid content of—. W. D. Bigelow and P. B. Dunbar. J. Ind. Eng. Chem., 1917, 9, 762—767.

THE acidity of plums, apples, and cherries appears to be due entirely to malic acid, which is present only in the free condition. Currants always contain citric acid, and, in some cases, also malic acid, whilst gooseberries contain a large proportion of malic acid, and also give strong reactions for citric acid. In some varieties of pear the acidity is

entirely due to malic acid, whilst in others citric acid predominates, and only traces of malic acid are present. In the cranberry and red raspberry, citric acid is probably the principal acid, whilst the pomegranate contains only citric acid, and the quince, peach, and banana contain malic acid and no citric acid.—C. A. M.

Food-colouring substances; Separation and identification of—. W. E. Mathewson. U.S. Dept. Agric. Bull. No. 448, Feb. 15, 1917. 56 pages.

THE scheme of analysis of dyestuffs described includes 130 chemical individuals in use or suggested for use in food products, with the eight permitted colours of the U.S. Dept. Agric., viz., Amaranth, Ponceau 3R, Erythrosin, Orange 1, Naphthol Yellow S, Tartrazin, Light Green S.F., yellowish, and Indigodisulphonic acid. The method of separation is based on the employment of immiscible solvents. For details of the separation and identification of the colouring matters the tables in the original must be consulted.

PATENTS.

Food; Process and apparatus for sterilising and preserving—. E. C. R. Marks, London. From Anchor Cap and Closure Corporation, New York. Eng. Pat. 108,146, Apr. 26, 1916. (Appl. No. 8214 of 1917.)

THE food is packed into containers and the air is then exhausted from the containers before the latter are sealed. The containers and their contents are next subjected to a sterilising temperature while an excess pressure is maintained on the exterior of the containers. This excess pressure may also be maintained while the containers are cooling.—W. P. S.

Milk; Dried— and method for producing the same. C. H. Campbell, Assignor to Borden's Condensed Milk Co., New York. U.S. Pat. 1,233,446, July 17, 1917. Date of appl., Dec. 21, 1915.

MILK is concentrated to about one sixth of its original volume, then mixed with water in quantity equal to about one half of the volume of the original milk, and the mixture is stirred, aerated, and dried. The product consists of a mass of mutually coherent milk solids with concavities filled with the aerating gas.—W. P. S.

Jelly-making product and process for producing same. R. Douglas, Rochester, N.Y. U.S. Pat. 1,235,666, Aug. 7, 1917. Date of appl., Apr. 12, 1915.

XIXB.—WATER PURIFICATION; SANITATION.

Culture media employed in the bacteriological examination of water; Studies on the ——. II. Neutral-red lactose peptone media. E. M. Chamot and C. M. Sherwood. J. Amer. Chem. Soc., 1917. 39, 1755—1766. (See this J., 1915, 730, 918, 1068.)

THE influence of the constitution of the culture medium upon the reaction produced by the growth of *B. coli* therein was investigated. The medium was placed in a fermentation tube consisting of an upright tube closed at the top and bent round at the bottom and enlarged into a wide bulb. A growth of *B. coli* in this apparatus produces gas and a change of colour in the tube to a fluorescent yellow, the colour in the bulb remaining red. It was found that the concentration of "neutral red" which gave the most decided colour change was 0.008—0.01%. The peptone could be varied from 2 to 5% without effect on the colour change. The most satisfactory acidity was + 1%. The presence of ammonium and calcium chlorides retarded the colour change, potassium and magnesium sulphates accelerated it, and potassium and sodium chlorides gave uniform results in 1% concentrations. The amount of lactose should be between 0.4 and 1.0%. The change of colour was found to arise not from the production of ammonia but from simple reduction, as the yellow compound readily changed to red again in presence of air. The yellow compound was found to be identical with that produced by the action of reducing agents on "neutral red," namely, dimethyldiaminomethylhydrophenazine. Wafers contaminated with the faeces of farm animals gave the change in this medium characteristic of *B. coli*. The authors prefer this medium to the lactose bile medium.

—J. H. J.

Nitrate in sewage; Determination of — by means of o-tolidine. E. B. Phelps and H. L. Shonb. J. Ind. Eng. Chem., 1917. 9, 767—770.

TWENTY-FIVE c.c. of the sample is boiled for about half a minute with 0.5 c.c. of a solution of sodium hydroxide and sodium chloride (5 grms. NaOH and 1.5 grms. NaCl in 100 c.c.), and the liquid cooled and made up to its original volume or weight. Of the supernatant liquid above the precipitated iron or manganese, from 1 to 10 c.c. (according to the proportion of nitrate present) is evaporated and the residue mixed with 0.2 c.c. of a solution of 0.4 gm. of o-tolidine in 100 c.c. of N/1 hydrochloric acid, and then treated with 0.5 c.c. of strong sulphuric acid, which is poured down the side of the vessel so that the liquids do not mix. After 5 mins. the sides of the basin are moistened with the liquid, and, after another half min. the liquid is diluted with about 5 c.c. of water, transferred to a colorimetric tube, and made up to 10 c.c., and the colour compared within 5 mins. with those given by standard nitrate solutions under the same conditions. Permanent standards may be prepared by diluting N/40 potassium bichromate solution to match solutions containing from 0.5 to 10.5 parts of nitric nitrogen per million after treatment with the reagent.—C. A. M.

Lactic organisms and streptococci; Similarity between — from the point of view of the action of antiseptics. C. and H. Cardot. Comptes rend., 1917. 165, 272—275.

EXPERIMENTS were made as to the antiseptic action of increasing amounts of phenol and sodium fluoride upon cultures of streptococci and lactic organisms. Results showed that small amounts of phenol had a slightly stimulating effect on both the cultures, as compared with cultures of the same organisms without the addition of the

antiseptic. Small amounts of sodium fluoride had no such effect. To produce a reduction in growth of 50% as compared with untreated cultures, 0.3 gm. of phenol per litre was required for streptococci and 0.8 gm. for lactic organisms, while 0.13 gm. of sodium fluoride per litre was required for streptococci and 0.2 gm. for lactic organisms. Streptococci are thus more sensitive to these two antiseptics than are lactic organisms. When the results are plotted, it is seen that the curves showing the action of the two antiseptics are quite different. The curve for sodium fluoride is of a hyperbolic nature, and is the same for both organisms. The curve for phenol is S-shaped, and is also almost the same for both organisms. From these results it is concluded that a rule established by experiments on a non-pathogenic organism will apply also to pathogenic organisms.

—J. H. J.

PATENT.

Extraction of fals. ammonia, and the like from organic refuse. Eng. Pat. 107,992. See 116.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine; Methyl derivatives of —. C. Mannich. Arch. Pharm., 1916. 254, 319—363. J. Chem. Soc., 1917. 112, i., 473—475.

ACCORDING to the constitution of morphine proposed by Knorr and Pschorr, the alkaloid functions as a tertiary base, as a phenol, and as a secondary alcohol. Theoretically, therefore, one trimethyl, three dimethyl, and three monomethyl derivatives should be capable of existence. Four of these are already known and the remaining three are now described. Methylcodeine methochloride, $C_{10}H_{16}O_3NCl$, colourless crystals, m.pt. 208°C., loses methyl chloride by heating under 2 mm. pressure and yields morphine OO-dimethyl ether, $C_{17}H_{17}ON(OCH_3)_2$, prismatic or tabular crystals, m.pt. 140—141°C. This method of demethylating quaternary bases is not applicable to any other morphine derivative. A second method of preparing the same dimethyl ether is the following. Morphine oxide or codeine oxide is shaken with a large excess of N/1-sodium hydroxide and methyl sulphate at 0°C., the solution is faintly acidified with hydrochloric acid and treated with concentrated aqueous potassium iodide, and the crystalline substance obtained, m.pt. about 253°C. (doubtless the hydriodide of morphine oxide dimethyl ether), is heated at about 80°C. with sulphurous acid and a little sodium bisulphite, and the solution is made alkaline and extracted with ether, whereby morphine OO-dimethyl ether, identical with that mentioned above, is obtained. Morphine methoxymethyl ether, $C_{17}H_{17}ON(OH)(OCH_2OCH_3)$, colourless needles, m.pt. 94—96°C., obtained by treating a suspension of the sodium derivative of morphine in cold chloroform with chloromethyl ether, is insoluble in alkali hydroxides, does not give a coloration with ferric chloride, but instantly develops a violet coloration (the morphine-formaldehyde reaction) with concentrated sulphuric acid. It is stable towards alkalis, but is converted by dilute acids into morphine, formaldehyde, and methyl alcohol. Heterocodeine (the monomethyl ether of morphine methylated at the secondary alcoholic group) is obtained by the following method. Morphine methoxymethyl ether is gently warmed with hydrogen peroxide, and the resulting syrup, which doubtless contains an amino-oxide, is treated with N/1-sodium hydroxide and methyl sulphate at 0°C., and the resulting solution is acidified with dilute sulphuric acid and treated with concentrated aqueous potassium

iodide solution; the precipitate is collected and warmed with sulphurous acid for two days, whereby heterocodeine, $\text{HO.C}_{17}\text{H}_{17}\text{ON}(\text{OCH}_3)$, crystals, m. pt. 242°C ., is obtained, which is isolated as the hydrochloride, prisms containing $2\text{H}_2\text{O}$, m. pt. 102°C . Heterocodeine is soluble in alkali hydroxides, develops a blue coloration with ferric chloride and a reddish-violet coloration with formaldehyde and sulphuric acid, and is shown to be a true derivative of morphine, not of *iso*- or ψ -codeine, by its conversion by diazomethane into morphine *OO*-dimethyl ether.

Cantharidin. W. Rudolph. Arch. Pharm., 1916, 254, 423—456. J. Chem. Soc., 1917, 112, i., 468—469.

The facts that the substance $\text{C}_{10}\text{H}_{14}\text{O}_3$, cantharidin, obtained by Anderlini in 1893 by reducing cantharidin by sodium and ethyl alcohol, is a neutral substance exhibiting the properties of a very stable lactone, and is not identical with the product obtained by the reduction of the "dibromide" of cantharidin, serve, in the author's opinion, to eliminate the second of Gadamer's three formulæ, *i.e.*, the one given in a previous abstract (this J., 1914, 1112). Further, the failure of the "dibromide" of cantharidin to yield a dimethyl ester is attributed to steric hindrance, and on this account, of Gadamer's remaining two formulæ for cantharidin, the preference is given to the following one:—

This preference is supported by the fact that cantharene, prepared by boiling the "dibromide" of cantharidin with 25% aqueous potassium hydroxide in an atmosphere of hydrogen, has a smaller exaltation of the molecular refraction than the values previously recorded.

Chrysarobin; Commercial. —. II. R. Eder, Arch. Pharm., 1916, 254, 1—33. J. Chem. Soc., 1917, 112, i., 464—466. (Compare this J., 1915, 681.)

In order to stabilise its reactive constituents, chrysarobin (obtained from the same consignment as that used in the oxidation experiments, *loc. cit.*) was first acetylated or benzoylated, and the reaction products were then separated and purified, and the various constituents isolated.

As the results of these experiments and of those previously recorded (*loc. cit.*), the following constituents of chrysarobin have been definitely identified: chrysophanic acid anthranol, emodin-anthranol monomethyl ether, emodin monomethyl ether, dehydroemodinanthranol monomethyl ether, and emodin (or emodinanthranol). The author has been unable to detect in his sample of chrysarobin Jowett and Potter's dichrysarobin methyl ether, dichrysarobin, and the substance $\text{C}_{17}\text{H}_{13}\text{O}_4$ (Chem. Soc. Trans., 1902, 81, 1577), Hesse's chrysarobol and chrysophanic acid anthranol methyl ether (this J., 1912, 357; 1917, 234), and Tutin and Clewer's chrysophanic acid and ararobinol (this J., 1912, 253; 1913, 1126); in other respects his results show an extensive agreement with those of the last-mentioned authors, which were attained by quite different methods.

American and oriental storax; Comparison of —. S. Jordan. J. Ind. Eng. Chem., 1917, 9, 770—771.

COMMERCIAL storax is usually derived from the "Liquidambar" tree (*Liquidambar orientalis*) of Asia Minor. The samples examined had the following characters:—Volatile matter, 20.35 to 27.64; ash, 0.28 to 4.48; insoluble in ether, 2.16 to 7.12; insoluble in alcohol, 3.25 to 7.98; cinnamene,

25.89 to 51.30; resin esters, 1.00 to 24.24; resin acids, 2.63 to 53.35; free cinnamic acid, 1.87 to 8.14%; acid value, 42.2 to 106.4; and saponif. value, 133.0 to 166.2. The liquid or semi-liquid balsam from *Liquidambar styraciflua* is known in U.S.A. as "sweet gum." A sample had the following characters:—Volatile matter, 22.37; ash, 0.32; insoluble in ether, 5.24; insoluble in alcohol, 6.64; cinnamene, 22.86; resin esters, 34.76; resin acids, 2.11; free cinnamic acid, 12.63; total cinnamic acid, 28.02%; acid value, 68.7; and saponif. value, 131.6. The experiments showed that "sweet gum" is a satisfactory substitute for commercial storax, that it contains more cinnamic acid, and has a superior odour to that of the imported article. The Southern part of the United States would be able to supply all the U.S. requirements for storax.—C. A. M.

Guanidine; Formation of—from thiourea and from cyanamide. E. Schmidt. Arch. Pharm., 1916, 254, 626—632. J. Chem. Soc., 1917, 112, i., 449.

The author finds that, contrary to the old statement of Hofmann, dicyanodiamide is not the only product obtained when thiourea in aqueous or aqueous-alcoholic ammonia solution is treated with yellow mercuric oxide for 24 hours at the ordinary temperature, guanidine also being produced, although not in large quantities. Cyanamide is first formed, which then mainly polymerises to dicyanodiamide, but also reacts with ammonia to some extent to form guanidine. The same two changes occur when a solution of cyanamide, prepared by very faintly acidifying a solution of sodium cyanamide with 98% formic acid, is treated with mercuric oxide and aqueous ammonia as above, but the quantity of guanidine formed is somewhat larger and becomes considerably greater when the reaction is effected in a sealed tube at 100°C .

Arsenic compounds (p-benzarsinic acid) and amino-acids and higher alcohols; Esters of aromatic —. E. Sieburg. Arch. Pharm., 1916, 254, 224—245. J. Chem. Soc., 1917, 112, i., 486—487.

p-BENZARSINE oxide (p-carboxyphenylarsine oxide) $\text{CO}_2\text{H.C}_6\text{H}_4\text{AsO}$, an amorphous powder which is extremely soluble in ether, is obtained by acidifying a solution of p-benzarsine iodide in aqueous sodium carbonate. When boiled with water, it is converted into p-benzarsenious acid, colourless needles, insoluble in ether. The oxide, which is at least ten times more poisonous than the hydrate, can be kept for at least eight days in a moderately concentrated aqueous solution of sodium hydroxide or carbonate at 0°C . without any appreciable diminution of its toxicity. Phenylarsine-p-carboxylic acid, $\text{CO}_2\text{H.C}_6\text{H}_4\text{AsH}_2$, colourless prisms, m.pt. $79^\circ\text{--}80^\circ\text{C}$., is prepared by reducing a methyl-alcoholic solution of p-benzarsinic acid with hydrochloric acid (sp. gr. 1.19) and zinc dust, the product being removed by distillation with steam. In the moist state it is very sensitive to atmospheric oxygen, immediately becoming yellow and changing apparently to p-arsenobenzoic acid.

In connection with the discussion (this J., 1916, 753) of the action in the organism of preparations containing arsenic, the fact that p-arsenobenzoic acid injected into the animal organism is eliminated partly in the form of benzoylglycine-p-arsinic (hippuro-arsinic) acid is important as showing that arsenic compounds are capable of reacting in the organism under certain conditions with the degradation products of the albumin molecule. The author has now prepared and examined a number of such compounds of amino-acids and aromatic arsenic compounds. p-Benzarsinic acid is produced almost quantitatively by heating p-tolylarsinic acid with nitric acid (sp. gr. 1.2)

for three hours at 170° C. in a sealed vessel. The *p*-tolylarsinic acid is conveniently prepared by the interaction of diazotised *p*-toluidine and sodium arsenite in alkaline solution. *p*-Benzarsinic acid is converted by a modification of Fournet and Oechslin's method (Fr. Pat. 441,215; this J., 1912, 844) into *p*-dichloroarsinobenzoyl chloride, which reacts with amino-acids (alanine, phenylalanine, tyrosine, leucine, aspartic acid, glutamic acid, and pentamethylenediamine) in the presence of aqueous sodium bicarbonate (sodium hydroxide in the case of tyrosine) to form, after acidification of the resulting solutions, the arsine oxide of the benzoyl derivative of the amino-acid. These arsine oxides are amorphous, white powders, which do not exhibit sharp melting points, are easily soluble in methyl or ethyl alcohol and in alkali hydroxides, carbonates, or bicarbonates, and do not dissolve in dilute hydrochloric acid; the oxygen of the AsO-group cannot be replaced by halogens or sulphur. They are oxidised to the corresponding arsenic acids by careful treatment with hydrogen peroxide in alkaline solution, and are reduced by sodium amalgam to arseno-compounds of the type

The latter are amorphous, yellow substances without definite melting points, but the arsenic acids are crystalline.

p-Dichloroarsinobenzoyl chloride reacts easily and smoothly with the higher alcohols. The reaction is effected in benzene solution in the presence of pyridine at the ordinary temperature, and finally on the water-bath. Myricyl alcohol yields myricyl benzoate *p*-arsine oxide, $\text{C}_{30}\text{H}_{47}\cdot\text{O}\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{AsO}$, which in acetone solution is oxidised to the arsenic acid, $\text{C}_{37}\text{H}_{67}\text{O}_5\text{As}$, pointed leaflets, by hydrogen peroxide, and is reduced to the arseno-compound, $\text{C}_{34}\text{H}_{110}\text{O}_4\text{As}_2$, yellow powder, by phosphorous acid. Cholesterol yields cholesteryl benzoate *p*-arsine oxide, $\text{C}_{34}\text{H}_{48}\text{O}_3\text{As}$, colourless powder; the arsenic acid, $\text{C}_{34}\text{H}_{50}\text{O}_5\text{As}$, forms pointed needles, and the arseno-compound, $\text{C}_{68}\text{H}_{96}\text{O}_4\text{As}_2$, is a yellow powder. The arsenic acid does not give Windaus's digitonin reaction.

p-Sulphomethylaminophenylarsinic acid. I. Abelin. Biochem. Zeits., 1916, 78, 191—196. J. Chem. Soc., 1917, 112, i., 487—488.

p-SULPHOMETHYLAMINOPHENYLARSINIC acid, $\text{SO}_3\text{H}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{AsO}(\text{OH})_2$, an *N*-substituted derivative of atoxyl, is prepared by treating the sodium salt of *p*-aminophenylarsinic acid with formaldehyde sodium bisulphite in concentrated solution and precipitating from this mixture the free acid with hydrochloric acid. The free acid forms needles which decompose at 148° C. The substance is much less toxic than atoxyl, and its action on trypanosomes is apparently much weaker.

Sozoiodol-mercury preparations; Simple method of estimating mercury in —. A. Herrmann. Arch. Pharm., 1916, 254, 498—500. J. Chem. Soc., 1917, 112, ii., 399.

THE mercury in *Hydrargyrum sozoiodolicum* (mercuric salt of di-iodophenol-*p*-sulphonic acid, $\text{C}_6\text{H}_2\text{I}_2\langle\text{SO}_3\rangle\text{Hg}$) is readily estimated as follows.

The preparation, 0.5 gm., is shaken with about 10 c.c. of water in a 200-grm. glass-stoppered bottle, treated with 2 grms. of potassium iodide, and, after the liberated mercuric iodide has dissolved, treated with 10 c.c. of officinal alkali hydroxide solution. A mixture of 3 c.c. of formaldehyde solution and about 10 c.c. of water is added, and the bottle is gently shaken for about one minute. After acidifying with 25 c.c. of dilute acetic acid, 25 c.c. of *N*/10-iodine solution is added, and the

excess of the iodine is titrated with *N*/10-thio-sulphate after all the mercury has been dissolved (1 c.c. of *N*/10-iodine = 0.01003 gm. of mercury = 0.031225 gm. of the mercuric salt).

The mercury in auogen (the mercurous salt, $\text{O}(\text{Hg}\cdot\text{C}_6\text{H}_4)_2\text{SO}_3\text{Hg}$) is estimated by treating 0.5 gm. with 2 grms. of potassium iodide and 25 c.c. of *N*/10-iodine, shaking the mixture for one to three minutes, and titrating the excess of iodine with *N*/10-thio-sulphate and starch solution (1 c.c. of *N*/10-iodine = 0.02006 gm. of mercury = 0.041256 gm. of the mercurous salt).

Acetylsalicylic acid and sodium salicylate; Determination of — in powders. R. Miller. Amer. J. Pharm., 1917, 89, 347—348.

ACETYSALICYLIC acid and sodium salicylate are determined in mixtures of the two by the following method:—A finely powdered weighed sample is mixed with an equal bulk of clean sand and extracted 10 times with a small quantity of ether. The combined filtered extract is evaporated to dryness and the residue weighed. The residue of acetylsalicylic acid should give a yellow coloration, becoming gradually deeper with concentrated nitric acid, an immediate purple coloration with Froehde's reagent, and a faint red coloration after one or two minutes with formaldehyde and sulphuric acid, but no coloration with selenious sulphuric acid, or with concentrated caustic soda. Sodium salicylate is determined in the residue from the ether extraction, to which the filter paper is added, by moistening it with dilute sulphuric acid, extracting ten times with small quantities of ether, evaporating the filtered extract to dryness, and weighing the residue of salicylic acid. It is identified by the ferric chloride test, and by giving the characteristic wintergreen odour on heating with several drops of methyl alcohol and concentrated sulphuric acid.—F. SP.

[Organic] acids; Identification of —. III. E. Lyons and E. E. Reid. J. Amer. Chem. Soc., 1917, 39, 1727—1750.

IN continuation of previous work (this J., 1917, 236 and 568), the authors have studied different methods for the preparation of *p*-nitrobenzyl bromide. The best method was found to be that suggested by Wachendorf, as follows: *p*-Nitrotoluene is heated in a sealed tube for several hours at 125°—130° C. with the calculated amount of bromine. The product is treated with alcohol from which it should crystallise readily, giving nearly white crystals melting at 90° C. With careful working a 50—60% yield is obtained. Further work has been done in preparing *p*-nitrobenzyl esters and studying their properties. Satisfactory results have been obtained with many monobasic, dibasic, and polybasic acids, but it was found that sulphonic acids do not yield esters of this type. Esterification has been tried as a means of separating and identifying mixtures of acids, and has proved successful in many cases.—L. A. C.

Ethyleneglycol; Preparation of —. B. T. Brooks and I. Humphrey. J. Ind. Eng. Chem., 1917, 9, 750—751.

A CHEAP method of preparing ethyleneglycol is to heat a mixture of ethylene chloride, sodium formate, and methyl alcohol in an autoclave. An excess of 6 mols. or more of methyl alcohol is used to increase the proportion of glycol formed by the alcoholysis of the glycol formate:—

The maximum yield is obtained by heating the

mixture for about 7 hours at 165° to 170° C., the pressure varying at that temperature from 240 lb. to 290 lb. per sq. in., and remaining at about 50 lb. (owing to decomposition of sodium formate) after cooling the autoclave. After cooling, the methyl alcohol solution is separated from the crystalline salt and sodium formate mixture, the latter washed with cold methyl alcohol, and the combined alcoholic solution distilled. A small amount (8 to 10% of the weight of dichloride used) consists of glycol diformate (b. pt. 174° C.).

—C. A. M.

Methyl alcohol; Detection of — by catalytic dehydrogenation. C. Mannich and W. Geilmann. Arch. Pharm., 1916, 254, 50—64. J. Chem. Soc., 1917, 112, ii., 392—393.

THE method consists in passing the vapour of the liquid under examination over pumice impregnated with reduced copper at 280°—300° C. The course of the decomposition has been already described (this J., 1916, 943). The formaldehyde produced is detected by the violet coloration it develops with morphine and concentrated sulphuric acid. The apparatus is figured and described. An aqueous solution containing 0.1% of methyl alcohol gives a distillate which develops the coloration very faintly after one hour and faintly after twenty-four hours. The method is very effective in detecting methyl alcohol in blood or urine, 0.01 grm. of the alcohol in 100 c.c. of blood or urine giving a positive result; the liquid must first be carefully fractionated to concentrate the methyl alcohol, and the fraction containing the latter must be boiled for some time with freshly ignited animal charcoal before being passed over the catalyst, although even with these precautions the catalyst is slowly poisoned. In order to detect methyl alcohol in the presence of ethyl alcohol, the mixture, diluted if necessary so that it contains about 50% of water, is passed over the catalyst, the distillate is heated in a vacuum to remove the acetaldehyde, and the residual solution is tested for formaldehyde as above. If the original mixture contains less than 1% of methyl alcohol, the diluted solution should be repeatedly fractionated before the test is applied to the fraction in which the methyl alcohol has been concentrated. One-half per cent. of methyl alcohol in brandy can be detected by this method.

Aluminium salts; Astringent action of —, especially of the formate. A. Loewy and R. Wolfenstein. Biochem. Zeits., 1916, 78, 97—111. J. Chem. Soc., 1917, 112, i., 497.

EXPERIMENTS are described which indicate the advantages of the use of the formate of aluminium as compared with the acetate. The former preparation is less irritant. It is best employed in solution which contains some sodium sulphate. Such a solution readily precipitates proteins and also produces contraction of the blood vessels.

Photography. [Sensitive paper for negatives.] E. B. La Rongery, Paris. Eng. Pat. 108,193, July 26, 1916. (Appl. No. 10,572 of 1916.)

A TRANSLUCENT paper base is prepared from a pure rag paper by chemical treatment to remove impurities, calendering three times under a heavy pressure, heating to about 80° C., and calendering at a lower pressure at 18° C. This base is coated with an emulsion prepared by adding a solution of potassium bromide 10 grms., ammonium bromide 30 grms., cadmium iodide 0.5 grm., and potassium iodide 0.5 grm., in distilled water 250 c.c., to a gelatin solution to which has been added 55 grms. of silver nitrate in 250 c.c. of distilled water, with sufficient ammonia to dissolve the precipitate first formed. The sensitive paper thus produced may be used instead of glass plates or celluloid films for the production of negatives.—B. V. S.

Silver from weak photographic emulsions; Process for recovery of —. F. F. Renwick, Brentwood, and B. V. Storr, Assignors to Ilford, Ltd., Ilford. U.S. Pats. 1,234,390 and 1,234,391, July 24, 1917. Date of appl., Oct. 17, 1916.

SEE Eng. Pats. 102,168 and 16,708 of 1915; this J., 1917, 47.

XXII.—EXPLOSIVES; MATCHES.

Trinitrotoluene; Inspection and testing of —. K. K. Stevens. J. Ind. Eng. Chem., 1917, 9, 801—803.

THE bulk of T.N.T. made in U.S.A. has, until recently, been shipped in the crude condition, the refined (i.e., recrystallised) grade only being made by about three plants. Quantities of about 2200 lb. are made at each operation or "run." The specifications usually require the product to be packed in cases or kegs of 50 to 100 lb. capacity, lined with oiled paper, and stating the shipment, "run," and case. *Sampling*:—Samples should represent amounts of about 4000 lb., and for convenience a composite sample representing two "runs" may be taken. The samples are taken from different parts of the case, mixed, and put into three 1 lb. bottles, for the buyer, seller, and referee respectively, the last being sealed by the buyer's inspector. *Testing—Colour*: Crude T.N.T. should be light yellow and the refined product cream-coloured, and not darken appreciably after heating for 2 hours at 100° C. *Fineness*: For crude T.N.T., 90% shall pass through a 10-mesh sieve; for refined T.N.T., 99% shall pass through a 12-mesh sieve; and for "explosders" all shall pass through a 30-mesh sieve. The crude product may frequently contain from 7 to 8% of lumps larger than specified. *Moisture* shall not exceed 0.10% for either grade (some specifications allow 0.15%), and shall be determined by drying 2 grms. for 24 hours over sulphuric acid. *Acidity*: The acidity, which should be nil, is determined by shaking 10 grms. of the melted sample with 100 c.c. of boiling water, cooling the mixture, pouring off the aqueous extract, and repeating the extraction with a fresh 50 c.c. of boiling water. The united

extract is titrated with *N*/20 caustic alkali solution, with phenolphthalein as indicator. One specification allows 0.03% of acidity as sulphuric acid. Insoluble matter must not exceed 0.15%. It is determined by boiling 10 grms. with 150 c.c. of 95% alcohol, collecting the insoluble matter on a Gooch crucible, washing it with not more than 150 c.c. of the solvent, and drying it for an hour at 95° C. In some specifications benzene is given as the solvent, and limits of 0.1% are allowed for refined, 0.15% for medium, and 0.2% for crude products. Ash is determined by slowly igniting 1 gm. in a platinum crucible. It should not exceed 0.1% in crude, or 0.05% in refined T.N.T. Nitrogen: Crude T.N.T. must contain not less than 18% of nitrogen determined by the Dumas combustion method, the minimum for refined T.N.T. being 18.2%. Diphenylamine test: Crude T.N.T. must contain no products which give the nitric acid reaction with diphenylamine and sulphuric acid. A pale blue colour is not decisive evidence of nitrates; it must be deep blue. Melting point: Crude T.N.T. should melt at 75.5° C. or higher; medium T.N.T. at 79.5° to 81.5° C.; and refined T.N.T. at 80° to 81° C. Solidification point: From 200 to 250 grms. of T.N.T. is heated below 90° C. in a dry 500 c.c. porcelain dish 15 cm. in diameter. After the sample has melted the heat is withdrawn and the liquid is stirred with the thermometer until it begins to crystallise and the temperature rises to its highest point. Stability tests:—These are not usually required for the crude material, but some specifications require it for the refined product. About 3 grms. of the substance is placed in a 6 in. test tube in which is suspended a strip of potassium iodide starch paper, on a glass hook which passes through the stopper. The tube is heated for 15 to 30 mins. at 65° C. according to the specification. No blue colour should develop.—C. A. M.

Trinitrophenylmethylnitramine (tetryl) and tetranitroaniline. C. F. Van Duin. Rec. Trav. Chim. Pays-Bas, 1917, 37, 111–117.

THE best method for the preparation of tetryl is as follows:—100 grms. of dimethylaniline is dissolved in 1 kilo. of concentrated sulphuric acid, keeping the temperature below 25° C. The solution is run, drop by drop, during 2 hours, into 500 c.c. of nitric acid (sp. gr. 1.49) previously heated to 40° C. and maintained between 38° and 42° C. The product is kept at 40°–42° C. for 3 hours, then heated slowly to 50° C. for half an hour, and finally to 55° C. for 2 hours. Next day the tetryl is filtered off, washed with water to remove acid, and finally with alcohol. Yield, 215 grms., nearly white, melting at 127° C. After recrystallisation from benzene, it melts at 130° C. and solidifies at 128.7° C. It still contains traces of sulphuric acid which can be removed by boiling it with water, but prolonged boiling causes appreciable decomposition with formation of picric acid.

(With B. C. R. van Lennep.) Tetranitroaniline is best prepared by dissolving 26 grms. of aniline in 700 c.c. of concentrated sulphuric acid, cooling to –5° C. and adding a solution of 16 c.c. of nitric acid (sp. gr. 1.49) in 80 c.c. of concentrated sulphuric acid. The mixture is kept in the cooling medium for 2 hours, after which 117 grms. of dry potassium nitrate is added, the temperature being kept below 50° C. The mass is allowed to stand for a day, is then heated to 50° C. for 1½ hours, and again left for a day. The tetranitroaniline is then filtered off, washed with 50% sulphuric acid and then with water. Yield, 26 grms., melting at 207° C. (corr.). From 25 grms. of *m*-nitroaniline, 30 grms. of tetranitroaniline is obtained. It is best recrystallised from glacial acetic acid. If acetone is used, it must be quite free from water; otherwise the tetranitroaniline is completely

converted into 2,4,6-trinitro-3-aminophenol. Tetranitroaniline begins to decompose after two months with formation of nitrous acid.—F. Sp.

PATENTS.

Blasting charges and cartridges. W. Weber. Hayingen, Germany. Eng. Pat. 15,065, Oct. 25, 1915.

A CASING made of a number of layers of paper placed loosely one upon the other so as to provide interior insulating spaces, some or all of which may be filled with straw, is charged with a mixture of one or more combustible substances—*e.g.*, sawdust, cotton wool, cork, linen—which will absorb liquid air, and one or more combustible metallic powders—*e.g.*, aluminium, antimony, magnesium, silicon. To obtain an increased disruptive effect a solid or liquid hydrocarbon is added, and the whole is saturated with liquid air by immersion immediately before use. The cartridge is fired by means of an electrical or cord fuse, wrapped in a combustible absorptive material. A diminished disruptive effect is obtained by the substitution of iron ore dust, such as minette, for the whole or a part of the metal.—E. W. L.

Powder; Apparatus for drying—W. A. Phillips. Philadelphia, Pa., Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,232,839, July 10, 1917. Date of appl. Aug. 13, 1913.

XXIII.—ANALYSIS.

Potassium; Destruction of organic matter in the determination of—P. L. Blumenthal, A. M. Peter, D. J. Healy, and E. J. Gott. J. Ind. Eng. Chem., 1917, 9, 753–756.

Loss of potassium by volatilisation when destroying organic matter by ignition is best prevented by converting the potassium salt into sulphate. For this purpose it is not sufficient merely to moisten the material with sulphuric acid, but enough acid must be added to oxidise the carbon, and to convert the whole of the inorganic salts present into sulphates. The most uniform results are obtained by a direct evaporation of the material with nitric and sulphuric acids prior to burning off the organic matter.—C. A. M.

Potassium; Modification of the cobalti-nitrile method of determining—R. C. Haß and E. H. Schwartz. J. Ind. Eng. Chem., 1917, 9, 785–786.

THE following method, applied to cement raw materials and the dust from the cement kilns, yields results in agreement with those given by the official methods of the Amer. Offic. Agr. Chemists:—Two grms. of raw material (or clinker) or 0.5 gm. of “treater” dust is triturated with 0.5 (or 0.25) gm. of ammonium chloride, and introduced into a platinum crucible containing about 2 grms. of calcium carbonate, and the whole is heated as in the J. Lawrence Smith method. After slaking, the mass is heated to boiling, the liquid filtered, and the residue washed 3 or 4 times with boiling water. The filtrate and washings are treated with an excess (5 to 10 c.c.) of acetic acid, and evaporated on a steam-bath until no odour of the acid is perceptible.—C. A. M.

CHEMICAL TRADES COMMITTEE APPOINTED.

The Minister of Reconstruction announces that he has appointed a Committee to advise him as to the procedure which should be adopted for dealing with the position of the Chemical Trades after the War. The Committee will be composed as follows: Sir Keith W. Price (Chairman), Ministry of Munitions; Mr. John Anderson, Secretary, National Health Insurance Commission (Eng.), attached Ministry of Shipping; Mr. J. F. Brunner, M.P., Mr. Charles Carpenter, D.Sc., M.I.C.E.; Professor J. G. Lawn, Explosives Department, Ministry of Munitions; Sir William Pearce, M.P.; Mr. K. B. Quinan, C.I.L., Explosives Supply Department, Ministry of Munitions; and the Rt. Hon. J. W. Wilson, M.P. Mr. G. C. Smallwood, of the Ministry of Munitions, will act as Secretary to the Committee. The Officers of Government Departments are appointed with the concurrence of their respective Ministers, and the other members of the Committee have been appointed at the suggestion of a representative meeting of Chemical Manufacturers. Dr. Addison has requested the Committee to conduct their deliberations with a view to the creation of some organisation which should be adequately representative of the trade as a whole and by means of which the trade may be enabled hereafter to continue to develop its own resources and to enlist the closest co-operation of all those engaged in the chemical industry.

RESTRICTIONS ON DEALING IN CALCIUM CARBIDE.

The following Order, dated 24th September, has been made:—

1. The Minister of Munitions hereby takes possession, as from the date hereof until further notice, of all calcium carbide, now or hereafter situated in the United Kingdom, except the stocks of persons who do not own more than half a cwt.

2. If any person having control of any calcium carbide to which Clause 1 hereof applies without the consent of the Minister of Munitions, sells, removes, or secretes it, or deals with it in any way contrary to any conditions imposed in any permit that may have been granted in respect thereof, he will be guilty of an offence against the Defence of the Realm Regulations.

3. No person shall, as from the date hereof, until further notice, buy, sell, or supply, except for the purpose of carrying out a contract in writing existing at the date hereof, enter into any transaction or negotiation in relation to the sale or purchase of, calcium carbide situated outside the United Kingdom, except under and in accordance with the terms of a permit issued under the authority of the Minister of Munitions.

4. No person shall, as from the date hereof until further notice, offer to sell, sell, supply or deliver any calcium carbide situated in the United Kingdom except under and in accordance with the terms of a permit issued under the authority of the Minister of Munitions.

5. All persons shall within seven days from the first day of each month commencing in the month of October, 1917, send in to the Controller of Non-Ferrous Materials Supply, AM2/H, Hotel

Victoria, Northumberland Avenue, London, W.C.2, monthly returns of: (a) All calcium carbide held by them on the last day of the preceding month; (b) All calcium carbide purchased or sold by them for future delivery and not yet delivered on such last day; (c) All calcium carbide delivered to them during the preceding month.

Notwithstanding the above, no return is required from any person where the total stock of calcium carbide in hand and on order for future delivery to him has not at any time during the preceding month exceeded half a cwt.

6. All applications in reference to this Order shall be made to the Controller of Non-Ferrous Materials Supply, as above, and marked "Calcium Carbide."

RESTRICTIONS ON THE MANUFACTURE AND SUPPLY OF CERTAIN GLASS AND GLASSWARE.

The Minister of Munitions has issued an Order, dated 19th September, imposing restrictions on the manufacture and supply of certain glass and glassware. The following is the text of the Order:—

(1) Every person shall as from the date hereof in the manufacture of glass and glassware comply with all directions and regulations applicable to such manufacture whether of general application or otherwise which may from time to time be given or made by the Director of Glassware Supply on behalf of the Minister of Munitions.

(2) As from the date hereof no person shall manufacture and no manufacturer shall supply or deliver any chemical and medical glass (excluding bottles) or any electric lamp glass or any glass tubing and rod, except:—

(a) In fulfilment of an order in writing given by an Ordering Firm (which expression shall include every person, firm or company giving an order) who shall have furnished to the manufacturer a declaration in writing stating that they are the holders of a direct contract from the Admiralty, War Office or Minister of Munitions, and specifying the reference and number of such direct contract, and stating that the glass specified in the order is required for the purpose of fulfilling such direct contract and for no other purpose, or

(b) In fulfilment of an order in writing which has been submitted to and approved by the said Director on behalf of the Minister of Munitions and a copy of which has been received by the manufacturer duly certified by the said Director or so approved, or

(c) Under and in accordance with the terms of a licence issued by the said Director on behalf of the Minister of Munitions.

(3) Every declaration made by an ordering firm for the purposes of this Order shall be signed by a partner, director, manager or other responsible official, and every statement contained therein shall be true and accurate.

(4) No person shall as from the date hereof buy, sell or deal in any chemical and medical glass, or any glass tubing and rod situated or to be manufactured outside the United Kingdom except under and in accordance with the terms of a licence issued by the said Director on behalf of the Minister of Munitions.

(5) No person shall as from the date hereof buy, sell or deal in any electric lamp glass, whether situated or to be manufactured in or outside the United Kingdom, except under and in accordance with the terms of a licence issued by the said Director on behalf of the Minister of Munitions;

provided that nothing contained in this clause shall be deemed to prohibit the supply or delivery of any electric lamp glass by the manufacturer thereof in accordance with the provisions of clause 2 hereof, or any purchase or sale of or other dealing in any electric lamp glass which forms part of a manufactured article the total value of which exceeds four times the value of the electric lamp glass forming part thereof and which is *bona fide* sold with such glass.

(6) All persons shall furnish to the said Director as and when required by him such returns of glass and glassware at any time manufactured, purchased, sold, supplied or delivered by them at such times and in such form as the said Director shall from time to time direct. All persons heretofore required to furnish returns relating to glass and glassware shall until further notice continue to furnish returns in accordance with such previous requirements.

(7) Nothing in this Order shall affect any obligation to obtain from the Board of Trade (Department of Import Restrictions), 22, Carlisle Place, London, S.W.1, or otherwise, import licences for the import of glass and glassware.

(8) For the purposes of this Order the expression "glass and glassware" shall include all kinds of glass or glassware made at the furnace, in the blow-pipe flame, or by any other process, or any of them; and the expression "chemical and medical glass" shall include resistance, chemical and bacteriological glassware, carboys, thermometers, miners' safety lamp glasses, X-ray tubes and valves, and glass for X-ray apparatus, artificial glass eyes, hospital glassware and glass vessels (graduated or otherwise) manufactured for the purpose of containing reagents, drugs, medicines pharmaceutical or biological substances or preparations, or any of them; and the expression "electric lamp glass" shall include all glass used or intended for use in the manufacture of electric lamps, except glass used or intended for use in lamp caps for insulating purposes, but shall not include glass shades and similar accessories; and the expression "glass tubing and rod" shall include all glass tubing and glass rod made by the process of drawing, or either of them.

(9) The Orders of the Minister of Munitions dated respectively the 2nd January, 1917, and 23rd March, 1917, relating to certain classes of glass and glassware are hereby cancelled, but such cancellation shall not affect the previous operation of those Orders or the validity of any action taken under them or either of them, or the liability to any penalty or punishment in respect of any contravention or failure to comply with the same respectively prior to their cancellation or any proceeding or remedy in respect of such penalty or punishment.

(10) All applications in reference to the above Order should be made to the Director of Glassware Supply, Ministry of Munitions of War, 117, Piccadilly, London, W.1.

(11) This Order may be cited as the Glass Control (Consolidated) Order, 1917.

Explanatory notes.

(a) Subject to any directions or regulations which may be given or made by the Director of Glassware Supply applicable to the manufacture of glass and glassware and to any priority directions a manufacturer may without licence accept any orders for glass and glassware, other than chemical and medical glass (excluding bottles) and electric lamp glass and glass tubing and rod, and manufacture the glass and glassware required to carry out such orders.

(b) As all chemical and medical glass (excluding bottles) and electric lamp glass and glass tubing

and rod are subject to the provisions of Clause 2 of the above order, no materials of this kind may be manufactured or supplied or delivered by a manufacturer unless the requirements of that clause have been complied with.

(c) In order to obtain the approval referred to under Clause 2 (b) of the above Order it will be necessary for ordering firms to submit their orders in duplicate to the said Director, accompanied by a covering letter setting out the purpose for which the glass and glassware is required. If approved one copy of the Order will be forwarded direct to the manufacturer duly certified and the other copy will be retained by the said Director. An advice will be sent to the ordering firm indicating the action taken in respect of such Order.

(d) Licences may be granted to manufacturers under Clause 2 (c) of the above Order to accept and carry out orders from dealers for reasonable quantities of the glass and glassware affected by that clause for the purpose of stock or export. Licences may also be given to manufacturers to manufacture limited quantities of such glass and glassware for their own stock or export. Licences to manufacturers to manufacture for their own stock may be given in such a form as will make it unnecessary to obtain any further licence for disposing of or dealing in the glass or glassware manufactured under such licence except in the case of electric lamp glass. A dealer who has obtained any glass or glassware in compliance with the provisions of clause 2 of the above Order will not require any further licence for disposing of or dealing in such glass or glassware, except in the case of electric lamp glass.

(e) In the case of electric lamp glass to be supplied by a dealer and not by a manufacturer, in order to obtain the licence of the said Director for the purchase or sale of or other dealing in electric lamp glass situated in the United Kingdom, the order on the dealer for which a licence is desired must be submitted in duplicate to the said Director, accompanied by a covering letter setting out the purpose for which the glass is required. If approved one copy of the order will be forwarded direct to the dealer and the other copy will be retained by the said Director. An advice will be sent to the ordering firm indicating the action taken in respect of such orders. No licences to purchase, sell or deal in electric lamp glass situated in the United Kingdom will be granted unless these conditions have been complied with.

(f) No licence is required under the above Order to be obtained for the purchase or sale of or other dealing in glass and glassware situated or to be manufactured outside the United Kingdom other than those types of glass and glassware affected by clauses 4 and 5 of the above Order.

(g) In order to obtain the licence of the said Director for the purchase or sale of or other dealing in any glass and glassware of the types affected by clauses 4 and 5 of the above Order situated or to be manufactured outside the United Kingdom, full details must be submitted in duplicate of the glass and glassware which it is proposed to buy, sell or deal in, accompanied by a covering letter stating the purpose for which the glass and glassware is required and to whom it is to be supplied. If approved one copy of such details will be certified as licensed and returned to the person submitting it, who must be the actual importer of the glass and glassware in question, and such certificate will constitute his authority for the purchase, sale or other dealing. No further licence will be required to dispose of or deal in such glass and glassware except electric lamp glass, provided nothing to the contrary is specified in the licence issued as authority for purchase, sale or delivery. A licence given to an importer to buy, sell or deal in glass

and glassware situated or to be manufactured outside the United Kingdom may be in such a form as will make it unnecessary for any further licence to be obtained, whether by the seller or the buyer for disposing of or dealing in such glass and glassware except in the case of electric lamp glass.

(h) A licence to buy, sell or deal in glass and glassware situated or to be manufactured outside the United Kingdom will only be given on condition that the importer renders to the said Director full and accurate returns of his imports, stock and deliveries of glass and glassware in accordance with the directions from time to time given by the said Director.

(i) Special attention is directed to clause 7 of the above Order relating to the necessity of obtaining import and other permits and licences which are or may be from time to time required.

ACETIC ACID AS WAR MATERIAL.

In pursuance of the powers conferred upon him by Regulation 30A of the Defence of the Realm Regulations, the Minister of Munitions has ordered that the "war material" to which that Regulation applies shall include acetic acid of all strengths.

All applications and enquiries regarding this Order should be addressed to the Director, Chemical Section, Trench Warfare Supply Department, King Charles Street, Westminster, London, S.W.1.

Manchester Section.

Meeting held at Grand Hotel on Friday, April 13th, 1917.

MR. J. H. ROSEASON IN THE CHAIR.

THE MANUFACTURE OF NITRIC ACID FROM NITRE CAKE.

BY DR. J. GROSSMANN.

In the manufacture of nitric acid it has in general been found impracticable to use equivalent quantities of nitre and sulphuric acid in such proportions as to produce the neutral sodium sulphate. A large excess of acid is used, with the result that the residue, which is termed "nitre cake," contains on an average about 28% of H_2SO_4 , the remainder being, with the exception of some impurities, sodium sulphate. There is thus a very large amount of sulphuric acid wasted, and when it became imperative to reserve practically all the available sulphuric acid for the manufacture of explosives, to the exclusion of other industries, nitre cake, on account of the free acid contained in it, appeared to be a suitable substitute for acidifying and similar purposes, particularly in the textile industries. Unfortunately, however, nitre cake is a troublesome material to handle, being produced in the shape of slabs 2 inches and more in thickness. It attracts moisture; it must be stored under cover, and special arrangements are required to keep the drainings from percolating into flues and foundations, all of which render it expensive to store. Notwithstanding its drawbacks,

nitre cake is now used, practically under compulsion by the Government, in the woollen, cotton and other textile industries, in galvanizing works, and in grease recovery, i.e., in general for acidifying purposes. Pressure has been put on manufacturers to utilise the cake in the manufacture of superphosphate and ammonium sulphate, but the products obtained are inferior in strength and quality, expensive to produce, and costly to transport. In almost every case in which nitre cake is used as a substitute for sulphuric acid, great inconvenience has been caused to the user who, moreover, has to pay from 15s. to 20s. and more per ton for an article which in normal times was valued at about 2s. 6d. per ton.

It is impossible to say how much of the total nitre cake produced has been used for these purposes; probably only a comparatively small fraction, and that only in such districts in which the users were not too far distant from the producers. By indirect calculations, it appears that the amount of sulphuric acid used for the manufacture of nitric acid cannot be less than three-quarters of a million tons per annum, possibly considerably more, and this would produce a somewhat larger amount of nitre cake containing a quantity of sulphuric acid equivalent to about one-quarter million tons per annum, and the question arises whether there might not be some means by which the manufacture of nitric acid as carried on at present could be improved in such a way as to liberate a certain amount of sulphuric acid for other purposes, and thus to some extent, if not altogether, relieve the textile and other industries from the necessity of using nitre cake. Anyone who has had to deal with nitre cake in the last year or two must have been struck with the fact that in many cases it contains undecomposed nitre far in excess of what is considered to be permissible in good work; this entails a waste of both nitrate of soda and sulphuric acid. It is also evident that there are cases in which, with a little more attention, a smaller amount of sulphuric acid might give as good results as those obtained at present. If the Government were to insist upon weekly returns from each nitric acid works, showing the amount of raw materials used, the amount of nitric acid (with tests) produced, the complete composition of the nitre cake (particularly in free acid, iron, nitrate of soda, and nitric acid), with occasional check tests made by independent parties, a saving in the use of sulphuric acid could no doubt be effected, and the compulsory use of nitre cake proportionately reduced. A saving of only 5% of sulphuric acid would amount to about 40,000 tons of H_2SO_4 per annum, which is equivalent to nearly 150,000 tons of nitre cake.

The utilisation of nitre cake for acidifying and neutralising purposes, which was adopted under the stress of necessity, represents no technical progress. Only one commercially appreciable ingredient, and that in quantity and quality the lowest, is rendered available, and the uses mentioned above can only be looked upon as temporary makeshifts to be replaced as soon as practicable by more rational methods of utilisation, i.e., by purely chemical manufacturing processes in which all the constituents of nitre cake are utilised so as to yield their utmost value.

Apart from methods which would achieve the purpose in an indirect manner, of which the one I brought to the notice of this Society last year (see this Journal, 1916, 155) is an instance, those methods which aim at the production of an acid and the simultaneous recovery of sodium sulphate appear to be the most likely to fulfil the above conditions. Amongst these the direct recovery of the sulphuric acid would be the simplest; but considerable difficulties, both in engineering and chemical details, may be anticipated and have so far been met.

with in that direction. The next important application would appear to consist in the use of nitre cake for the manufacture of hydrochloric acid, and this has been carried out for a number of years. Technically there are no difficulties in it which could not be overcome, though commercially it might in normal times not have been an unqualified success. It must, however, be borne in mind that in those times the value of hydrochloric acid was extremely low, and now that the acid itself is sold at many times the price it used to obtain formerly, the possibilities of commercial success are far more promising. It does not appear that the process has received any special attention from the Government though hydrochloric acid is far more suitable for a number of purposes than nitre cake, and could also be utilised for the manufacture of bleaching powder, of which large quantities will be required for disinfecting purposes in the near future to prevent epidemics.

The most rational of all possible processes for the utilisation of nitre cake would appear to be one by which nitric acid could be produced from it; in that case, we should either be in a position to increase our output of nitric acid by 30 or 40% with our present supply of sulphuric acid, or to produce the same amount of nitric acid as at present from a greatly reduced quantity of sulphuric acid. In the latter case, there would be the further advantage that the quantity of nitre cake as compared with that produced at present would be considerably reduced; also, that the reduced quantity of sulphuric acid required for nitric acid would mean a reduction in the shipment and importation of the raw material used for the manufacture of sulphuric acid, *i.e.*, pyrites, amounting probably to over 200,000 tons per annum.

For some time I have been attempting to solve this problem, and I have found that under certain conditions in a mixture of sodium nitrate, nitre cake, and charcoal or other suitable form of carbon, the sodium nitrate is completely decomposed, with a steady evolution of nitrous fumes and without frothing, at a comparatively low temperature, and that in the reactions which take place no reduction to nitrous oxide or nitrogen occurs, so that the yield of technically available nitrogen compounds is practically quantitative. The conditions under which this takes place are as follows:—The ingredients must be very finely ground and intimately mixed; the carbon must be present in excess, and a current of air must be passed through the system during the whole of the operation.

There is, of course, no difficulty in grinding sodium nitrate or carbon. As regards nitre cake, it is known that it has been and is ground very finely in the Oehler-Meyer process of producing hydrochloric acid. It is stated by some authorities that there is no difficulty in obtaining a product of which 90% would pass through a 50-mesh sieve. Other authorities state that the wear and tear on the disintegrators is considerable. I have found it troublesome to grind nitre cake in the laboratory, and in order to render my process free from any possible objection as to its practicability on a large scale, I have endeavoured to find a means by which nitre cake could be ground more easily. I have succeeded in this by pouring the molten nitre cake on to a thin layer of sodium carbonate and chilling the mass quickly. The carbon dioxide which is liberated leaves the mass after cooling in a spongy condition, quite friable and easy to powder in a porcelain mortar. 5% of Na_2CO_3 on the nitre cake produces excellent results; with a little modification, such as diluting the sodium carbonate with powdered sodium sulphate, even 2½% of Na_2CO_3 will give a good spongy material. The molten nitre cake coming from the stills could at once be treated in this manner, and old stock could be re-melted and thus rendered useful.

The nitre cake which I used for my experiments

contained after treatment with sodium carbonate 23% of free sulphuric acid. It was ground very finely in a porcelain mortar, and mixed with an excess of finely ground coke and such a quantity of sodium nitrate as would ultimately produce a slightly acid sodium sulphate. Although I did not sieve the ground nitre cake, it was in the state of a powder of which the greater part, if sieved, would pass through a 60 mesh. The mixture was placed in a retort which was connected with a series of bottles containing a solution of caustic soda, and the mass was heated gradually to 250° C. whilst a current of air was drawn through the system. It was found that the fumes changed colour at different temperatures, which points to the fact that different reactions take place at different stages; thus the evolution of red fumes commences below 70° C.; at 100° C. the fumes are getting yellow; at a higher temperature, they become colourless, and at 199° C. they again show a brown coloration, which decreases with a further rise in temperature. The analysis of the residue showed that at 100° C. under 50% of the nitre was decomposed; at from 120° to 130° C., about 70%; at from 140° to 160° C., 87%; at 250° C., the decomposition was complete. It was found that substantially all the nitrogen was recoverable in the caustic soda as nitrate or nitrite, which proves that in work on a manufacturing scale it will be possible to convert into and practically recover all the gases evolved as nitric acid. A typical test showed the following results:—

Recovered as sodium nitrate	54.5
Recovered as sodium nitrite (calculated as sodium nitrate) ..	42.8
Undecomposed	0.9
Loss (by difference)	1.8
	<hr/> 100.0

Even with five condensing bottles nitrous fumes were still going away unabsorbed, and it may therefore be assumed that the loss of 1.8% was due to incomplete absorption and that the reaction is quantitative so far as nitrogen compounds recoverable as nitric acid are concerned.

It is well known that the oxidation of nitrous fumes to nitric acid is a time reaction, and it is extremely difficult, if not impossible, in carrying out quantitative experiments of this kind in the laboratory to give sufficient time to the gases to interact. On a large scale, these difficulties are overcome by having large chambers in which the mixture of nitrous fumes and air is allowed to take place over a certain period. In the Birkeland and Eyde process, the difficulties of producing nitric acid from these nitrous fumes have been solved. Considering that the gases in the process which I have described are produced at a very low temperature, *viz.*, 250° C., whereas in the atmospheric process a temperature of from 1500° to 3000° C. is required, and that the gases evolved in my process are far more concentrated in proportion to the air mixed with them, it is more than probable that oxidation and condensation will be much easier to conduct and that a higher strength acid will be obtained in my process than in the Birkeland and Eyde and similar processes, which only produce acid of 50% HNO_3 . Where the strongest acid is required, it will, of course, be necessary to redistil the acid by any of the means used at present for that purpose. For many purposes, such as the manufacture of nitrate of ammonia and similar applications, an acid of 50% or even less would be quite suitable, and in these cases, no further concentration of the acid would be required. For the manufacture of sulphuric acid, the application of this process would be particularly suitable, as the gases evolved might be passed straight into the chambers or the Gay-Lussac tower. The manufacture of calcium

nitrate or nitrite (and through these of ammonium nitrate and sodium nitrite) could be combined with this process, with or without the simultaneous production of nitric acid.

The residue produced is in a friable condition. As it is practically free from chloride, which in the manufacture of nitric acid and in this process, is evolved as nitrosyl chloride, it is in a particularly suitable condition for the manufacture of the highest strength caustic soda by the Leblanc process, and the coke which has been used in this process is thus not lost, with the exception of the small quantity which has been used up in the reaction.

In a series of further experiments, I omitted the carbonaceous matter altogether, and used only a mixture of nitre cake and sodium nitrate very finely ground as stated above and intimately mixed. The experiments were carried out in exactly the same way as in the series of experiments with carbonaceous matter, air being passed through the system whilst the mixture was heated up gradually, the gases evolved being absorbed in caustic soda solution. I found that here also the decomposition was complete at 250° C. At 100° C., white fumes came from it and the mass in the retort swelled slightly on the top. The fumes up to 140° C. were colourless or slightly yellow; between 160° and 190° C., brown fumes appeared which decreased and became again yellowish at over 200° C., and towards the end, at 240° C., there appeared to be no fumes given off. In a typical experiment I recovered:—

As sodium nitrate	85.2
As nitrite, calculated as sodium nitrate	13.1
Undecomposed	0.3
Loss (by difference)	1.4

Having worked in exactly the same way as previously, the results are comparative. They show that in this second method a much greater amount of nitric acid is evolved as such, and that the oxidation and condensation of the other oxides of nitrogen will be far more complete and more rapid than is the case in the previously described method, so that by this process, with less condensing plant, a much stronger acid should be obtained. The resulting mass is not quite as friable as in the carbonaceous method, but considering the low temperature at which the reaction takes place, it is not likely that this would interfere with the continuous working of the process on a manufacturing scale. Either of the two processes could be worked in ordinary muffle furnaces by hand, or by mechanical means. The salteake obtained from either of the two processes contained from 2 to 4% of free sulphuric acid.

The grinding of the nitre cake should not interfere with the commercial success of the process. With proper supervision, it should not cost more than 5s. per ton to grind nitre cake in the state in which it is produced at present, especially if the slabs were made of lesser thickness. If it were found advisable to use my method for producing spongy nitre cake by means of sodium carbonate, the extra labour involved would be balanced by the lower cost of grinding, and as for every hundredweight of sodium carbonate used one and a third hundredweight of sodium sulphate would be obtained, in a charge with 2½% of sodium carbonate, the chemical would only add about 1s. 3d. to the cost per ton of nitre cake. All charges involved for grinding and mixing may therefore be taken at under 10s. per ton of nitre cake, and as less than 3 tons of nitre cake will be sufficient to decompose 1 ton of sodium nitrate and produce over 3 tons of salteake, whilst saving 1 ton of sulphuric acid, there is the value of 3 tons of salteake and that of 1 ton of sulphuric acid as a set-off against the expense of grinding and mixing. On the prices ruling before the war, this would show an advantage over the present mode of working of nearly £6 per ton of nitre;

on present prices, it would show an advantage of over £10 per ton of nitre. The actual working expenses should be no higher than in the ordinary method of making nitric acid, as any extra expense in labour would be fully balanced by the reduced quantity of fuel required and the lesser wear and tear on the plant, owing to the low temperature at which the reactions take place. Either of these methods would enable the nitric acid manufacturer to decompose each ton of nitrate of soda with three-fourths of the acid which is required at present, and to get rid of a troublesome by-product; and there appears to be no reason why he should not manufacture caustic soda on the spot from the salteake produced, and thus add further to his revenue.

Since writing this I have found a method by which nitre cake can be obtained as a fine powder at about 2s. per ton; this will further reduce the cost of producing nitric acid from nitre cake as given above, and as no sodium carbonate is used in this method, 2½ tons of nitre cake will be sufficient to decompose one ton of sodium nitrate.

DISCUSSION.

The CHAIRMAN said that Dr. Grossmann was to be congratulated on the success of his method, especially having regard to the application of so low a temperature. Some 20 years ago a process had been described in the Journal of this Society (Vol. XII., p. 44) for the utilisation of nitre cake by the cooling of practically saturated solutions of the substance, when owing to the conditions of temperature neutral sodium sulphate and free sulphuric acid were formed. For technical purposes, such as for souring, this would be a convenient way of obtaining a moderately strong sulphuric acid.

Mr. W. THOMSON enquired whether it was possible to dispense with the use of sodium bicarbonate and obtain a friable, spongy mass by blowing air into the molten nitre cake, after the manner of making slag wool.

In analyses of samples of nitre cake he had made, he was struck by the completeness with which the nitric acid had been removed from the nitre used.

Mr. STANLEY SMITH said that those who had not had an opportunity of observing the Birkeland-Eyde process in operation could not possibly form a conception of the difficulties experienced in the absorption of the nitrous gases. The gases obtained by Dr. Grossmann were doubtless very much more concentrated than those obtained in the nitrogen fixation process, but considerable capital expenditure would be required for their recovery. It was by no means possible to recover the whole of the gases in water. It was necessary that the last gas should be washed with an alkaline solution. Milk of lime had not been used in the Birkeland-Eyde process for a long time. In Dr. Grossmann's process it was apparent that soda ash must be used for part of the absorption, and this would mean that a certain amount of nitrous gases would be recovered not as nitric acid but only as sodium nitrate. Dr. Grossmann pointed out that his process was practically a quantitative reaction; carried out on a small scale, however, a 1.8% loss was found. The recovery of the nitric acid would entail a further loss, which would result in additional expense. If by this process most of the nitrous gases were absorbed in water, the maximum strength of the nitric acid obtained without a very elaborate absorption plant, would be about 30%. This did not appear to be of very much value under present circumstances, since the chief demand is for the strong acid.

A remark had been made that it might be possible to utilise nitre cake in the manufacture

of chlorine. The utilisation of large quantities of chlorine in an economical manner was the only drawback to the manufacture of alkali by electrolysis on a largely increased scale. Should it be possible to find a remunerative outlet for large quantities of chlorine, there was no doubt that the quantity of alkali manufactured by the ammonia-soda process would be very much reduced.

Dr. GROSSMANN, in reply to the Chairman, said that it was quite correct that a solution of nitre cake stronger in sulphuric acid than the ordinary solution could be obtained by crystallising out some of the sodium sulphate; but at the same time the impurities in the nitre cake would also be in a more concentrated form in the solution.

The process Mr. Thomson suggested, of exposing molten nitre cake to an air blast, might produce a substance similar to slag wool, but would not have the effect of rendering the mass friable. As regards the nitric acid and nitrate left in nitre cake, his experience had been quite different from Mr. Thomson's.

Referring to Mr. Stanley Smith's remarks, Dr. Grossmann said that the difficulty of absorbing the unoxidised nitrous fumes would be considerably less than in the Birkeland-Edyde process and even if the last traces had to be absorbed in soda, the amount of the latter required should only be a negligible quantity. The assumption that the condensed nitric acid would only contain 30% HNO_3 was contrary to the best authorities, such as Dammer, who state that the strength of acid recovered by the atmospheric process is 35° B., i.e., 50% HNO_3 . Such an acid would have to be concentrated to render it applicable for certain, though not for all, purposes. This was successfully done now, and improvements were constantly being made in that direction, and were to be found in the patent literature.

The reaction was practically quantitative, and the figure 97.3% represented the actual quantities of nitric and nitrous acids recovered and obtained by distillation of a mixture of nitre cake, nitre, and charcoal.

Mr. Smith's remarks on the chlorine industry of the future were purely controversial; the fact remained that at present hydrochloric acid was scarce and absurdly high in price, and that under these circumstances the use of nitre cake for its production would be advantageous.

Correspondence.

UTILISATION OF NITRE CAKE.

SIR,

Of the two methods which I have worked out for the utilisation of nitre cake, and which are published in this issue of the Journal, only the first method, dealing with the reactions which take place when nitre cake, sodium nitrate, and coke are heated, was brought before the Manchester Section; the second method, owing to a prohibition from the Army Council (since withdrawn), was not published at the time. The first method was submitted in November, 1916, to the Explosives Department of the Ministry of Munitions which, of its own volition, tried it in the Research Laboratory and reported that only 33% decomposition was found. A full account of the mode in which I had carried out my experiment was then forwarded, and elicited a further statement that "working substantially on my lines" the Department only obtained 33% decomposition of the nitre, against 97% which I claimed and 99% which has since been found by an independent analytical chemist of the highest repute. On my offering to demonstrate in my laboratory the correctness of my statements, I received a communication which without direct admission implied that the experiments carried on by the Ministry of Munitions might not have been on exactly the same lines as mine; but without giving any reasons based on facts the Department declined to go further into the matter.

The adherence to a result which shows a discrepancy of 66% can only be accounted for by assuming that the matter was *a priori* not considered of sufficient importance to receive serious attention. It is entirely within the discretion of the Explosives Department of the Ministry of Munitions to subject a process to examination or not, but it is of national importance that if a process is submitted to investigation the experiments should be carried out in accordance with the inventor's instructions and in the most careful and efficient manner. Unless this is done, no sound conclusions as to the value of a process can be arrived at.

I am, etc.,

J. GROSSMANN.

Manchester,

22nd September, 1917.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, *Jein et Cie.*, 56, Rue Ferou 8. Paris (2e.).

Patents from 1908 to date, *L'imprimerie Nationale*, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Filtration: Principles of—, D. R. SPERRY. Met. and Chem. Eng., 1916, 15, 198-202; 1917, 17, 161-166.

IN the filtration of a liquid containing a solid in suspension, there are two concurrent processes: (1) Flow of liquid through the porous filtering medium, and (2) building up of the filter cake. The author shows experimentally that the rate of flow is directly proportional to the pressure above the liquid, which is in accord with the Poiseuille formula for the eddyless flow through tubes. Filtration is a capillary phenomenon. A mathematical expression is deduced connecting the two processes, 1 and 2, and this has been

tested experimentally by studying the time-discharge curves of a filter through which a suspension of kieselguhr in water was forced under pressure. The requirements of the equation deduced were nearly but not exactly fulfilled. This was traced to sedimentation of the suspension which thickened the filter cake at a rate faster than that due to passage of the liquid through it. By eliminating sedimentation the validity of the mathematical treatment was confirmed.—H. J. H.

Pervaporation, perdistillation, and percrystallisation. P. A. KOBER. J. Amer. Chem. Soc., 1917, 39, 914-948.

WATER held in a collodion or parchment membrane container evaporates through the walls as though

no membrane were present. This phenomenon is called pervaporation. The speed of pervaporation is so great that it is impossible to heat water to the boil by means of a Bunsen flame when the water is in a closed collodion container. The method may prove useful for concentrating sterile preparations, such as foodstuffs, toxins, and anti-toxins, under sterile conditions. For example a globular collodion container fitted with a glass tube at the top and closed with a cotton plug and tin-foil, was sterilised and filled with 300 c.c. of a sterile meat infusion broth medium. By pervaporation in a large incubator, the infusion was converted into a product resembling Liebig's beef extract in colour, taste, and consistency. Perdistillation, or distillation by pervaporation, can be effected at low temperatures under ordinary pressure as well as *in vacuo*. When a dialysable constituent of a liquid in a collodion or parchment membrane container reaches saturation, crystallisation usually takes place on the outside of the container; this is termed percrystallisation. The crystals are dry and practically free from mother-liquor. They dissolve when a little water is added inside the container.

Thermostat: A high temperature — J. L. Houghton and D. Hanson. Inst. of Metals, Sept. 19, 1917. [Advance copy.] 12 pages.

THE instrument consists of a double-walled vessel made into a furnace by winding it with nichrome wire. This vessel acts as a gas thermometer, and the variations in the pressure of the air contained in it operate a contact-breaker which regulates the current supplied to the furnace. The contact-breaker is a U-tube, containing mercury and fitted with two platinum contacts, which breaks the relatively small current of a solenoid relay; this in turn pulls a fork into or out of two mercury cups, thus cutting off or putting in an external resistance to the furnace. One side of the relay is connected to the furnace bulb, and the other to the closed bulb of a simpler thermostat, similar in principle to the main thermostat. This device is necessary to protect the instruments from the variations otherwise caused by changes in atmospheric temperature and pressure. Using a modified bulb, slow rates of cooling, of the order of 1° or 2° C. per day, can be obtained.—J. H. P.

Decolorising-carbon. See IIb.

PATENTS.

High vacua; Means and apparatus for obtaining — The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 108,596, Oct. 18, 1916. (Appl. No. 14,821 of 1916.)

IN apparatus of the type described in Eng. Pat. 105,357 (this J., 1917, 584), the blast of mercury vapour is made to enter the condensing chamber in a downward direction, and this chamber is connected with the vessel to be exhausted through a trap, so that mercury vapour cannot enter the vessel.—W. H. C.

[*Mercury*] boiler. W. L. R. Emmet, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,236,155, Aug. 7, 1917. Date of appl., Nov. 26, 1913.

IN a mercury boiler consisting of vapour and liquid chests connected by bent header pipes, the joints between the pipes and headers are enclosed and connected with a means of producing a vacuum to draw off any mercury vapour, and with a drain to draw off any liquid mercury which may leak through the joints.—W. H. C.

Boiler-feeding means. W. L. R. Emmet, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,236,154, Aug. 7, 1917. Date of appl., Nov. 26, 1913.

A NUMBER of generators for liquid of high boiling point are connected together at about the liquid level by pipes which dip down so as to form practically U-bends between the individual generators; the bends contain sufficient liquid to prevent vapour passing from generator to generator, but allow the passage of liquid. The vapour space of each generator is connected with a common vapour main by a pipe having a non-return valve. Each generator is connected with a gravity feed main by a pipe provided with a float valve.

—W. H. C.

Catalytic material; Method of making — C. B. Morey and C. R. Craine, Assignors to Larkin Co., Buffalo, N.Y. U.S. Pat. 1,232,830, July 10, 1917. Date of appl., Feb. 2, 1916.

AN insoluble compound of a catalytic metal, for example, an insoluble salt of nickel, is suspended in water and mixed with an absorbent non-catalytic material, such as fullers' earth, from which the moisture and gases have been driven off by heat, so that the solid compound enters into the interstices of the absorbent material. The mixture is then dried, ground, and reduced.—W. H. C.

Mixing machine. T. J. Sturtevant, Wellesley, Mass., Assignor to Sturtevant Mill Co. U.S. Pat. 1,234,230, July 24, 1917. Date of appl., Oct. 7, 1916.

A HORIZONTAL cylinder, open at one end, is mounted within a casing so that it can be rotated in either direction. Materials to be mixed are charged through a shoot which passes through the casing into the open end of the cylinder, and are mixed by rotating the latter. When the mixing is complete, the direction of rotation is reversed and the contents are discharged into a shoot placed in the lower part of the casing.—W. H. C.

Solutions, emulsions, and the like; Method of thickening (condensing) or drying — P. Askenasy, Karlsruhe, Germany, Assignor to Akt.-Ges. für Chemische Produkte vorm. H. Scheidemandel, Berlin. U.S. Pat. 1,234,714, July 31, 1917. Date of appl., Dec. 12, 1916.

SMALL globules or beads of glue or gelatin are added to the solution or emulsion to be thickened and kept in contact therewith for a sufficient time to absorb a portion of the liquid present; the beads containing the absorbed liquid are removed and a thickened residue thereby obtained; the separated beads are dried and used again for a similar purpose.—J. F. B.

Furnace-charging system. L. D. Anderson, Midvale, Utah, Assignor to United States Smelting, Refining and Mining Co. U.S. Pat. 1,234,998, July 31, 1917. Date of appl., Dec. 27, 1915.

AN elongated furnace has a charging, measuring, and mixing hopper, of approximately the same length as the furnace, which is charged with the different ingredients from various bins. The materials are mixed, formed into a layer of approximately the same length as the furnace, and then charged into the latter.—W. H. C.

Cooling tower. C. W. E. Clarke, Brookline, Mass. U.S. Pat. 1,235,291, July 31, 1917. Date of appl., Oct. 28, 1916.

A COOLING tower contains a series of rows of baffle-plates, each consisting of a sheet of metal, straight at one end and curved at the other to form a channel for collecting and conveying the deposited spray. The baffle-plates are arranged

in alternate rows, those in one row being oppositely disposed and not in alignment with respect to those in the next row.—B. V. S.

Straining liquids: Apparatus for —, J. E. Fitch and F. C. Stephens, Assignors to R. A. Wittmann, Buffalo, N.Y., U.S. Pat. 1,235,672, Aug. 7, 1917. Date of appl., Apr. 1, 1914.

The straining surface is maintained in a clean condition by an adjustable scraper which is supported on rollers and passes over the surface. The scraper is formed of a band of resilient material the lower edge of which is divided by transverse slots into a number of resilient fingers which pass over and conform with the irregularities of the straining surface.—W. H. C.

Rotary-mill construction. M. F. Williams, Assignor to Williams Patent Crusher and Pulverizer Co., St. Louis, Mo., U.S. Pat. 1,235,868, Aug. 7, 1917. Date of appl., Oct. 28, 1915.

A MILL of the disintegrator type is fed from a hopper which opens into the upper part of the grinding chamber and is provided with a slide regulator. A conduit which extends in a centrifugal direction from the point of the casing just below that at which the feed hopper is attached, serves as a receptacle for any foreign material that may get in to the mill and be thrown out by the beaters, and also as a conduit through which air enters the grinding chamber.—W. H. C.

Crushing machinery. R. W. Pringle, Gatooma, S. Rhodesia, S. Africa, U.S. Pat. 1,237,383, Aug. 21, 1917. Date of appl., Feb. 2, 1917.

SEE Eng. Pat. 102,767 of 1916; this J., 1917, 123.

Compressing machines or apparatus, also adapted for expressing oil or other liquid from seeds and other materials. Eng. Pat. 108,329. See XII.

Machines for expressing oils or liquids from seeds, nuts and other solids. Eng. Pat. 108,515. See XII.

HA.—FUEL; GAS; MINERAL OILS AND WAXES.

Peat: Economic utilisation of — from Châteauneuf-sur-Rhône (Hle-et-Vilaine). C. Galaine, C. Lenormand, and C. Houlbert. Comptes rend., 1917, 165, 337–340.

EKENBERG (Fr. Pat. 331,720 of 1903; this J., 1903, 1122) has shown that peat heated under pressure to a temperature above 150° C., loses its gelatinous consistency and can then be easily dried by compression. The process has not yet been applied industrially, but the product possesses very striking properties, being no longer peat, and for convenience the authors have given it the name "tourbon." The calorific value of "tourbon" is 10% higher than that of dried peat and is about 6500 kilo.-cal. The hydro-cellulose being destroyed in passing through the autoclave, "tourbon" does not absorb moisture after drying. "Tourbon" is particularly rich in volatile matter, one sample of anhydrous "tourbon" showing 61.3%. The authors first reduce the water content of the peat in a continuous press (Mabille, Aurep system, etc.) at a pressure of 50 to 100 kilos. per sq. cm. (700 to 1100 lb. per sq. in.), bringing the water content of the briquettes produced down to 60%. The briquettes are placed in layers in carriages and

heated for 25 minutes in horizontal autoclaves by means of steam at 160° C. Freed from gelatinous matter the product dries rapidly in air, but still better in chambers heated by the furnace gases. A great part of the heat is recovered by a recuperative system, an efficiency of 91% being attained with a consumption of one kilo. of coal for the production of 11 kilos. of "tourbon." "Tourbon" can easily be made to contain only 20 to 25% of water and may be used in place of wood for household purposes, in gas producers, or in distillation processes for production of combustible gas and by-products (sulphate of ammonia, methyl alcohol, coke, etc.).—J. E. C.

Gas-firing: New system of —, A. C. Ionides, Inst. of Metals, Sept. 19, 1917. [Advance copy.] 9 pages.

For efficiency in gas heating, an unvarying, correctly proportioned mixture of gas and air is necessary. Constancy of composition may be attained by passing the gas and air through the author's

"mixing balance," by which a variation in the pressure of either brings about a corresponding variation in the other. The balance consists of a sensitive floating bell, the under side of which is subjected to the static pressure of the gas supplied, and the upper side to that of the air supplied. It will be seen from the diagram that if the gas pressure increases the bell will rise, thereby tending to close the gas valve below and open the air valve above. If the air pressure increases the bell will fall, tending to close the air valve and open the gas valve. The effect is to maintain a constant ratio of gas to air after passing through the bal-

ance, though either be varied. As an indicator of the quality of the gas mixture made, an incandescent gas mantle is used, the brightness of which is a maximum for theoretical mixtures. The author proposes to use a crucible furnace, in which the gas and air burn in a cylindrical inner chamber, the waste gases passing from the top and downwards through a surrounding annular space, and out of the furnace into a flue connected to the centre of the base. Furnaces on the same principle have been constructed for heating machine gun barrels. Where a suitable atmosphere, oxidising or reducing, must be maintained, the use of the mixing balance permits this, and an improvement in the quality of the products.—H. J. H.

Regenerators or heat interchangers for gas producer plants. A. H. Lynn, London, L. A. Riley, New York, and N. E. Ramburh, London. Eng. Pat. 108,710, Aug. 11, 1916. (Appl. No. 11,471 of 1916.)

A HEAT interchanger for use in connection with a gas generator consists of a series of concentric chambers in which the heating medium (producer gas) and the medium to be heated (steam and air)

alternate. The producer gas enters tangentially at 11', and passes successively through the chambers 10, 5, and 9, escaping at 18, whilst the steam and air to be heated enter at 20, pass

successively through the chambers 8, 1, and 1, and escape at 12'. The heating spaces for the air and steam may take the form of a series of vertical tubes arranged within a cylindrical inner and an annular outer heating chamber.—J. E. C.

Inflammable liquid, and process of producing same. J. Greer, East Orange, N.J. U.S. Pat. 1,236,557, Aug. 14, 1917. Date of appl. May 24, 1915.

A VOLATILE inflammable liquid is produced from the liquor condensed in the manufacture of illuminating gas, when oil is used in the process of manufacture. The liquor is deposited before the gas leaves the low-pressure gasholder. It is collected without exposure to the atmosphere, held in a closed vessel at the pressure of the gasholder, and distilled at such pressure at temperatures rising to 150° C., the distillate being collected.—J. E. C.

Hydrocarbons; Treatment of — for the production of other hydrocarbons of different specific gravity and boiling point. L. B. Cherry, Kansas City, Mo., U.S.A. Eng. Pat. 101,330, Dec. 1, 1916. (Appl. No. 17,250 of 1916.) Under Int. Conv., Feb. 21, 1916.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Decolorising-carbon. Chem. Trade J., Sept. 15, 1917, 218.

EXPERIMENTS have been carried out by the

sectional chemical committee of the Royal Society on the production of decolorising-carbons similar to the German and Dutch products known as "eponite" and "norite." From microscopic examination of various charcoals it was concluded that eponite is made from a mixture of coniferous wood, such as pine or cedar, and angiospermous wood, such as poplar or willow. A preliminary treatment of the wood on the lines of Ostrejko's Eng. Pat. 18,040 of 1900 (this J., 1902, 58) gave improved results. In the experiments wood as sawdust or shavings was boiled with a solution of calcium or magnesium acetate, then dried, and carbonised at a red heat with addition of lime or magnesia, and the charcoal washed with hydrochloric acid, then with water, dried, and again heated to redness. The addition of starch mullage to the treated wood increased the decolorising power. Charcoals made at higher temperatures (approaching white heat) from a mixture of pine and willow treated with calcium acetate and starch and from cedar wood treated with calcium acetate, were superior to eponite. Experiments were carried out on willow and cedar as two distinct types of wood under the following conditions:—(1) Natural wood, without treatment; (2) Wood treated with milk of lime; (3) Wood treated with calcium acetate. These were carbonised at white heat, and the charcoal washed with hydrochloric acid, then with water, and finally heated. Process (1) gave a charcoal useless for decolorising; (2) and (3) gave very active charcoals, all equal to eponite. The calcium-acetate charcoals were slightly more active than the milk-of-lime material and the type of wood had little or no influence on the result. The process used was:—Sawdust from pine, willow, or cedar was mixed with milk of lime to form a dough, and the mixture heated to drive off some of the water. The mass was placed in a crucible, covered with a layer of lime, and raised to a temperature approaching white heat. The charcoal was boiled with excess of hydrochloric acid, filtered, washed, drained, and heated in an iron retort to a red heat. The charcoal was then powdered and sifted through a No. 60 sieve. For carbonising a No. 6 salamander crucible heated in a Fletcher radial injection furnace was used.—J. E. C.

Electrode; Arc-lamp —. W. R. Mott, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,235,396, Aug. 7, 1917. Date of appl. Sept. 25, 1914.

THE electrode contains calcium fluoride, an oxide of uranium, and a conducting body of carbon.—B. N.

III.—TAR AND TAR PRODUCTS.

Tar; Dehydration of —. G. H. Sharples, N. Brit. Assoc. Gas Managers, Sept. 7, 1917. Gas J., 1917, 139, 469—471.

A COMPARISON of tars from horizontal and vertical retorts shows an increased yield of crude naphtha, light oils, and creosote from vertical retorts, with a lower specific gravity and a decreased yield of pitch. A more detailed comparison gives the following results for vertical retort tar and horizontal retort tar respectively in lb. per ton of coal carbonised:—Total naphthas (90's benzol and toluol and solvent naphtha), 3.549 and 3.021; 60's carbolic acid, 1.557 and 0.124; cresylic acid, 8.574 and 3.234; creosote, 55.304 and 26.902; pitch, 62.901 and 87.7. The rectified naphthas (90's benzol, 90's toluol, and solvent naphtha) from the vertical retort tar contained 19, 12, and 6% paraffins, as against a maximum of 1% from horizontal retort tar. In dehydration considerable quantities of creosote are carried over but conversely considerable quantities of naphtha are left in the tar. A large part of the tar acids is recovered in the crude oil taken off in dehydration, but 50% is left in the dehydrated tar. A comparison of light oils from dehydration plants with light oils as obtained by the ordinary method of distillation is given, along with an epitome and diagram of the general arrangements of a dehydration plant. The following results of a test are given:—Total tar used, 349 galls.; quantity per hour, 87.25 galls.; time exposed to heat, 34.5 mins.; temperature of leaving coil, 236 C.; light oil recovered, 192 galls.; water, 19 galls.; dehydrated tar, 125 galls.; specific gravities: crude tar, 1.08; light oil, 1.002; dehydrated tar, 1.16; viscosity of prepared tar, 66 seconds. The free carbon in the prepared tar was 6.01%, as against 5.001% in the crude, indicating that the tar does not suffer decomposition in passing through the coil. One serious drawback is the quantity of valuable products left in the dehydrated tar.—J. E. C.

Sulphonation kettles. F. Pope, Met. and Chem. Eng., 1917, 17, 177—180.

THE methods of regulating the temperature and effecting agitation in sulphonating vessels are discussed. Temperature is usually regulated by using a jacket through which low-pressure steam or water is passed. For temperatures above 110 C. high-pressure steam or superheated water can be used. Vessels for use with high-pressure steam have been made by casting them with wrought iron coils in the wall of the vessel. Another method is to make a jacket of boiler plate and line it with cast iron. There are limitations to the use of superheated steam at low pressure as its thermal capacity diminishes at higher temperatures, so that it becomes an unsatisfactory medium for carrying heat. Heat may be applied by circulating hot mineral oil through the jacket and a coil placed in a furnace. The oil must be carefully dehydrated and if heated to above 150° C., a reflux condenser must be employed to prevent loss of lighter fractions. Temperatures of 300° C. may then be maintained. The vessels may also be fire-heated. Various types of agitator are described. U-shaped stirrers may be placed eccentrically to give better agitation. Propeller agitation is largely used. The speed and size of the propeller must be adjusted to the type of vessel and contents, to give good results. This is a disadvantage where the nature of the liquid changes during a reaction. Two propellers on one shaft may be used with varying pitches and throwing in opposite directions. The shaft is preferably placed slightly off centre.—H. J. H.

Amines; Catalytic decomposition of —. *Formation of aniline from substituted anilines.* P. Sabatier and G. Gaudion. Comptes rend., 1917, 165, 309—313.

FINELY divided nickel, produced by the reduction of the oxide at a temperature below 700° C., is capable of decomposing various amines. At 356° C., nickel converts cyclohexylamine into aniline, whilst the reverse reaction takes place below 180° C.; under similar conditions, piperidine yields pyridine, primary amines are converted into nitriles, and methyl-*o*-toluidine into indole. In many cases, ammonia is split off; ethylamine yields ammonia and ethylene, which in turn is decomposed with the formation of carbon, hydrogen, methane, and ethane. Benzylamine yields toluene and ammonia. Methylaniline and dimethylaniline in contact with nickel at 350° C. yield benzene, aniline, ammonia, etc.; ethylaniline and diethylaniline react in a similar way.—W. P. S.

Preparation of nitro-derivatives of toluene. Kidokoro. See XXII.

IV.—COLOURING MATTERS AND DYES.

Palatine Chrome Black 6B; Preparation of—
I. Tomioka. Kogyo-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 29, 577—587.

1-AMINO-2-NAPHTHOL-1-SULPHONIC acid was prepared by the following methods: (A) α -nitro-naphthalene was heated with sodium bisulphite solution (over 20% SO_2), and the 1-aminonaphthalene-2,4-disulphonic acid produced was submitted to alkaline fusion; (B) 1-nitroso-2-naphthol was heated with 35% sodium bisulphite solution; (C) Orange II. was reduced by stannous chloride or zinc dust and hydrochloric acid, the 1-amino-2-naphthol produced was treated with bleaching powder, and the resulting β -naphthoquinone- α -chlorimide treated with sodium bisulphite solution. By using one of these methods a yield of 94% of the theoretical quantity was obtained. 24 parts of 1-amino-2-naphthol-4-sulphonic acid was dissolved in 11.3 parts of 15% ammonia solution diluted with 60 parts of water, and 58.2 parts of zinc chloride solution (40 B.; sp. gr. 1.381) added; the zinc salt was cooled in ice, and 16 parts of 90% sodium nitrite in 50 parts of water added gradually at 2—5.5°C., the temperature being subsequently raised to 13° in 2 hrs., kept at 25—30°C. for 1 hr., and at 40—45°C. for 1 hr. The diazo solution was cooled to 30°C., and 39 parts of 25% acetic acid added; after stirring for 1 hr., 40 parts of soda ash was added gradually, the solution was warmed to 40°C., and 16 parts of β -naphthol dissolved in 6 parts of caustic soda and 30 parts of water at 80°C. added with vigorous stirring; after stirring for 5 hrs. at 50°C., the zinc salt of the dyestuff was salted out, and converted into the free acid by concentrated hydrochloric acid; the yield was 53.6 parts, corresponding to 95.8% of theory.—F. W. A.

PATENTS.

[*Trisazo*] *colouring matters; Manufacture of*—
E. F. and H. W. Ehrhardt, Birmingham. Eng. Pat. 108,613, Nov. 22, 1916, and Jan. 6, 1917. (Appl. Nos. 16,752 of 1916 and 301 of 1917.)

DIAZOTISED *p*-phenylenediamine-azo-salicylic acid is combined with picramic acid-azo-*m*-toluylenediamine, *m*-phenylenediamine, or -chloro-*m*-phenylenediamine. The products dye chrome-mordanted wool a yellowish shade of brown than picramic acid-azo-*m*-toluylenediamine, faster to light than the monoazo dyestuff, and of equal fastness to scouring and milling.—F. W. A.

[*Trisazo*] *dyestuffs*. J. H. Stebbins, jun., New York. U.S. Pat. 1,235,253, July 31, 1917. Date of appl., Jan. 9, 1917.

1,8-DIHYDROXYNAPHTHALENE-3,6-DISULPHONIC acid is first combined with tetrazotised benzidine and then with a diazotised amine, and the products combined with a naphtholsulphonic acid. The dyestuffs produced give bluish or purplish shades on cotton from a sodium sulphate bath, and blue to black to brown shades on wool from an acid sodium sulphate bath. The product using picramic acid and 1,4-naphtholsulphonic acid is specially laimed.—F. W. A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Straw. Utilisation of surplus—.

IN anticipation of a surplus production of straw in Scotland next year, amounting to over 420,000 tons, a Memorandum has been prepared by the Consulting Chemist to the Highland and Agricultural Society of Scotland. The Memorandum

states that the use of straw in this country as a constituent in the manufacture of paper has been largely curtailed owing to irregularities of supplies and fluctuations in prices. Prior to the war the supply of esparto was quite regular and ample, and was obtainable at more or less regular and moderate prices. Esparto and wood pulp have been the raw materials most largely used hitherto in the manufacture of cheap writing papers and the better class of printing papers. Paper manufacturers see no reason why straw should not be much more largely used in the manufacture of various grades of paper in the United Kingdom, provided constant supplies can be obtained, and provided also that farmers will take the trouble to keep straw reasonably free from stalks of thistles, etc. Straw pulp may be looked upon as a substitute for esparto, although it does not seem probable that it can ever entirely supersede that product. The best quality of straw pulp could be freely used in the hardening of ordinary writing paper, which is largely composed of wood and esparto pulps, but which could be made entirely from wood and straw pulps. Experiments have recently been carried out in two Scottish mills for the purpose of determining the yield, and of testing the utility, of straw pulp. Both wheat and oat straw were tested, and fairly satisfactory results were obtained. A yield of pulp was obtained from oat straw equal to 35 per cent. of the weight of bone-dry straw. Among possible consumers of straw must be included the manufacturers of straw boards. Up to the present time the United Kingdom has taken supplies of these boards entirely from abroad. The utilisation of straw for straw boards could be effected by paper manufacturers if they cared to augment their present machinery by the special machinery which would be necessary. The cheapest straw boards are made from straw and waste material, and it is these that are imported from abroad. Boards for expensive books are of British manufacture. It may be possible, says the writer of the Memorandum, for United Kingdom manufacturers to turn out suitable straw boards, such as are found on the covers of ordinary books. The Memorandum also discusses the utilisation of straw for increasing the yield of nitrogen in the soil, and also its utilisation for feeding.

Pulp and paper industry of Canada. O. F. Bryant. Pulp and Paper Mag. J. Roy. Soc. Arts, 1917, 65, 619—626, 631—639.

At the present time there are about 80 pulp and paper mills in Canada. The percentage proportions of the different types of pulp manufactured in Canada in 1915 were: Mechanical, 52.9; sulphite, 33.5; sulphate, 13.1; soda, 0.5. Spruce was used to the extent of 50% of the total pulp manufactured, balsam fir 33%, while the remainder was made up of hemlock, jack pine, and poplar. In most cases no logs under 1 in. diam. are accepted; the amount of bark on a log is about 10% by weight and the loss of weight in removing it by a disc barker is about 20%. With barking drums a considerable saving is effected, the yield of air-dry pulp per cord being 1700 lb. with disc barkers and 1980 lb. with drum barkers. In the manufacture of mechanical pulp, cold-ground pulp is ground with plenty of water and is suitable for finer products, while hot-ground pulp, in the production of which the quantity of water is restricted and the temperature rises to 66°C., is suitable for fast, coarse work, such as news paper manufacture. In the manufacture of sulphite pulp, rotary sulphur kilns give more efficient results than the old type of horizontal burner. Another modern type consists of a vertical cylindrical shell at the top of which is a melting pot; the molten

sulphur drips down the tower over shelves which cause it to travel from side to side exposed to the action of the ascending air. In Canada both the limestone process and the milk of lime process are employed for the production of the liquor. The pulp digesters are lined with acid-resisting flint brick jointed with a mixture of litharge, glycerin, and quartz. These bricks are set over a course of ordinary bricks cemented with Portland cement and quartz. Pulp is digested by the rapid method at a maximum pressure of 75 lb. per sq. in. and a temperature of 165° C. and by the slow "Mitscherlich" process at a maximum pressure of 55—60 lb. In the manufacture of soda pulp the wood is chopped more finely than for sulphite pulp; digestion with caustic soda is carried out in upright digesters under a pressure of 100—125 lb. per sq. in. for about 8 hours. The sulphate process has been established in Canada for about 10 years and is used chiefly for the manufacture of "kraft" pulps; various inferior qualities of wood can be worked by this process which are unsuitable for the manufacture of sulphite pulp. Digestion is carried out sometimes in stationary digesters and sometimes in "tumblers" revolving on their short axis, having a maximum capacity of 2½ tons. The pulp is preferably washed in closed "diffusers" by means of weak liquors from previous charges. Evaporation of the black lye is performed in a combination of a multiple effect evaporator and a disc evaporator heated by the gases from the calcination furnaces; the latter consist of a rotary furnace placed in front of a smelting furnace in which a very high temperature is maintained in order to burn the carbon and reduce the sodium sulphate. For bleaching wood pulp many of the mills are equipped with electrolytic plant for preparing chlorine and caustic soda, the chlorine gas being absorbed in milk of lime. In 1908, 64% of the pulp-wood cut was exported in the raw state, whereas in 1915 the raw wood exported was only 11.1%. During that period the export of pulp-wood has increased by only 6.7%, whereas the export of wood-pulp has increased by 190%. At the average rate of 10 cords of wood per acre, a mill producing 200 tons of news paper per day would require the product of 9000 acres per year and allowing 40 years for a crop, such a mill would be served by a tract of 400,000 acres with systematic cutting and re-planting. Canada is producing about 1800 tons of news paper alone per day, and the total cut of pulp wood in 1915 was 2,355,550 cords. The total production of pulp in 1915 was 1,074,805 tons, of which 743,776 tons was mechanical pulp. The industry is concentrated in the provinces of Quebec and Ontario. The estimated amount of paper produced is 6,752,000 lb. per 24 hours. Developments are at present under way which will increase the daily output of pulp by 880 tons.—J. F. B.

PATENTS.

Coated fabric. E. W. Adams and S. G. W. Farthing, London. Eng. Pat. 108,376, Aug. 28, 1916. (Appl. No. 12,138 of 1916.)

THICK twill canvas is coated on both sides with a composition consisting of hard paraffin, 2 parts; soft paraffin, 4 parts; wood charcoal, 0.5; and powdered talc, 0.5 part. The ingredients are melted together, stirred until cold, and rubbed in cold.—J. F. B.

Wool, hair, or like substances contaminated with lime; Method of deliming —. J. Lucas, Passaic, N.J. U.S. Pat. 1,235,214, July 31, 1917. Date of appl., June 1, 1916.

MATERIAL such as wool, hair, or bristles, contaminated with lime, is steeped in a bath containing a pure culture of butyric acid Schizomycetes, such as *B. bonoprius* or *B. subtilis*; the bacilli in the bath are nourished during the deliming process

by a regulated supply of food so as to maintain the natural functions of the bacilli until the lime has been dissolved.—J. F. B.

Rice straw: Process for producing fibrous material from —. J. K. Toles, San Francisco, Cal., Assignor to Union Fibre Co., Winona, Mich. U.S. Pat. 1,235,258, July 31, 1917. Date of appl., Mar. 1, 1915. Renewed June 15, 1917.

RICE straw is boiled in an alkaline solution in order to break down the substances surrounding the fibres; the material is then washed in water and treated with an acid solution.—J. F. B.

Retting. B. S. Summers, Port Huron, Mich. U.S. Pat. 1,235,738, Aug. 7, 1917. Date of appl., Aug. 24, 1914.

A RETTING solution is prepared by dissolving albuminous material in a solution of sodium sulphide; the fibre is steeped in this solution and simultaneously subjected to heat and pressure, and the albuminous matter is subsequently precipitated in the fibre by treating the latter with an oxidising solution, such as bleaching powder.—J. F. B.

Cellulose compound and method of making the same. E. L. Bloch-Pimentel, Paris. U.S. Pat. 1,234,720, July 31, 1917. Date of appl., June 24, 1915.

CELLULOSE is treated with formaldehyde and ferric chloride, dried *in vacuo*, and heated in an oven sufficiently to form trioxymethylene and to cause this to react with the cellulose in the presence of the ferric chloride.—J. F. B.

Pyroxylin composition. W. E. Masland, Philadelphia, Pa., Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,234,921, July 31, 1917. Date of appl., June 19, 1914. Renewed Feb. 19, 1917.

PYROXYLIN is combined with 2—10% of aldol and 10—60% of a vegetable oil, e.g., castor oil, the amount of aldol and oil being between 40 and 75% of the constituents.—J. F. B.

Insulating material [from fibre]: Process of producing an —. W. Schewelin, Moscow, Russia. U.S. Pat. 1,235,061, July 31, 1917. Date of appl., July 9, 1911.

FIBRE for use as an insulating filling material, is washed, dried, and lixiviated in a solution of caustic and calcined soda; it is then again washed in hot water together with disinfecting and "non-odour developing substances," and dried in the presence of formalin vapour.—B. N.

Obturator material and method of making same. M. W. Marsden, Philadelphia, Pa. U.S. Pat. 1,235,220, July 31, 1917. Date of appl., July 8, 1913.

CORN (maize) stalks are cut in pieces and digested with steam under pressure to free them from saccharine and fermentative matter; this is separated from the digested mass and the latter is treated with alkali to remove the incrusting matter. The comminuted mass of fibres and pith is compressed to a block having a cork-like texture characterised by the property of suddenly swelling when wet.—J. F. B.

Wood and other cellulose-containing materials; Art of transforming —. G. W. Herbein, San Francisco, Cal. U.S. Pat. 1,235,895, Aug. 7, 1917. Date of appl., Aug. 5, 1916.

WOOD or other cellulose-containing material is boiled in paraffin or paraffin and resin for about 40 minutes at 340°—400° F. (171°—205°C).—J. F. B.

Cellulose; Method for the manufacture of —.
Apparatus for boiling fibre for the manufacture of cellulose. H. B. Ellis, Assignor to J. W. Wilhelm, Pahnetto, Fla. U.S. Pats. 1,236,072 and 1,236,370, Aug. 7, 1917. Dates of appl. Jan. 24 and Jan. 12, 1917.

FIBROUS material is shredded and the fibre separated from the dust. The fibre is heated in a pre-heating arrangement and a solution of caustic soda, previously heated, is introduced; the mixture is agitated during the operation of pre-heating and is subsequently brought to the boiling point. The apparatus comprises a series of tubular chambers, superposed and in parallel, having connections whereby an undulated passage is formed for the cellulose material. A steam pipe extends longitudinally through each tubular chamber to heat the cellulose material, and means are provided for conveying the material from a container through the heated passage. The container is surrounded by a jacket for preheating the material, the jacket being connected with the steam heating arrangement, and means are provided for disintegrating or breaking up the material as it leaves the heated passage.—J. F. B.

Paper [ornamental]; Manufacture of —. J. W. Mackenzie, London. From The Strathmore Paper Co., Mittineaque, Mass., U.S.A. Eng. Pat. 108,340, July 27, 1916. (Appl. No. 10,660 of 1916.)

A COLOURING or decolorising medium is applied to the uneven surface of the sheet or web of paper by means of a pressure roller to which the medium is supplied, e.g. by a brush spraying apparatus: the medium is thus transferred to the paper under rolling pressure and displaced from the elevated portions of the paper into the depressions. The uneven surface may be obtained by putting out of action the suction box in front of the dandy roll, so that the pulp is banked up and crushed under the dandy, and the coloured medium may be sprayed on to the upper couch roll.
 —J. F. B.

Fibrous materials; Separating impurities from waste —. Naamlooze Vennootschap Neo-Cellulose Maatschappij, Rotterdam, Holland. Eng. Pat. 108,434, May 2, 1916. (Appl. No. 3560 of 1917.) Addition to Eng. Pats. 24,057 of 1912 and 105,055 of 1916 (this J., 1913, 1104, and 1917, 868).

For removing printers' ink from waste papers a mixture of a foam producer and foam stabiliser is employed, the latter of which may amount to 20% of the mixture. A soap such as sodium stearate may serve as the foam producer and a vegetable or animal fat or solid or semi-solid hydrocarbon such as margarine or vaseline as the stabiliser. The mixture is produced in the form of a homogeneous, permanent, marketable mass. (Reference is directed under Sect. 7, Sub-section 4, of the Patents and Designs Act, 1907, to Eng. Pats. 12,385 of 1884; 11,981 of 1886; 5981, 7830, and 9857 of 1888; 21,431 of 1891; 19,732 of 1893; 24,240 of 1903; 29,113 of 1909; 17,714 of 1911; 24,795 and 29,122 of 1913; this J., 1885, 550; 1887, 727; 1889, 290, 714; 1892, 446; 1894, 962; 1904, 195; 1910, 1214; 1912, 812; 1914, 1215; 1915, 144.)—J. F. B.

Paper; Manufacture of glazed or loaded —, and coating and loading materials therefor. N. Statham, Hastings-on-Hudson, N.Y., U.S.A. Eng. Pat. 108,783, Nov. 8, 1916. (Appl. No. 16,028 of 1916.)

SEE U.S. Pats. 1,209,221 and 1,209,222 of 1916; this J., 1917, 212.

Paper pulp; Machine for staining —. W. W. Beaumont, London. U.S. Pat. 1,237,280, Aug. 21, 1917. Date of appl. Jan. 4, 1916.

SEE Eng. Pat. 17,552 of 1913; this J., 1914, 916.

Process of dyeing. U.S. Pat. 1,236,868. See VI

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Dyeing, scouring, and washing wool and other fibrous materials; Machines for —. J. and R. Whitaker, Dewsbury. Eng. Pat. 108,809, Jan. 23, 1917. (Appl. No. 1106 of 1917.) Addition to Eng. Pat. 101,060 (this J., 1916, 961).

IN dyeing and like machines of the type specified in the main patent, the side tipping discharge mechanism for the hinged inner chamber is operated by power-controlled overhead lifting gear which is arranged so that the lift is applied in an approximately circumferential direction to secure a wider tipping movement, and is combined with spring buffer and stop devices.—F. W. A.

Dye-beck. C. Buhl, Assignor to The Johnson Van Vlaandaren Machine Co., Paterson, N.J. U.S. Pat. 1,232,653, July 10, 1917. Date of appl. July 20, 1916.

AN apparatus for treating fabrics (see fig.) comprises a wheel or the like for advancing the fabric, journaled in a support on a horizontal axis, a

swinging fabric-guiding structure pivoted in the support on a horizontal axis above the wheel, and a link connecting this structure with an eccentric part of the wheel. The fabric-guiding portion of the structure is below the wheel and consists of a pair of co-acting fabric-guiding rollers, and means are provided to transmit rotary motion from the wheel to the rollers.—F. W. A.

Dyeing hanks and fabrics; Machine for —. L. S. Thompson, Brooklyn, N.Y., Assignor to Simultaneous Dyeing and Drying Co. U.S. Pat. 1,236,788, Aug. 14, 1917. Date of appl. Mar. 9, 1917.

A DYEING and drying machine consists of a vat containing a pair of wheels adjustable on a rotary axis, with curved ribbons mounted at the inner side of the wheels to support the material on and between the wheels.—F. W. A.

Detergent, bleaching, and disinfecting composition. F. F. Carmona, Assignor to Compania Exploradora Navezten, Mexico. U.S. Pat. 1,237,267, Aug. 14, 1917. Date of appl. Aug. 29, 1914.

A CLEANING and bleaching composition having disinfectant properties consists of the reaction

products of sodium carbonate, caustic soda sodium chloride, chloride of lime, sodium bisulphite, and the "saponifying-bark" derivative "shixhi."—F. W. A.

Dyeing; Process of—J. Puring, Assignor to Robeson Process Co., New York, U.S. Pat. 1,236,868, Aug. 14, 1917. Date of appl. Sep. 16, 1916.

TEXTILE materials are treated first with a solution obtained by the interaction of commercial concentrated sulphite waste liquor and iron sulphate, and afterwards with a colour-developing substance, e.g., a solution containing pyrazolol.—F.W.A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Potassium chloride from mother liquor in manufacture of sea-salt. T. Nishimura, Kogyo-Kwakaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 587—621.

THE annual production of bittern in Japan is 240,000 tons, and its composition when freshly obtained is: 12.27—20.63% $MgCl_2$, 2.30—3.48% KCl , 0.26—0.47% $MgBr$, 6.04—7.62% $MgSO_4$, 2.90—7.96% $NaCl$, and 67.53—69.30% water; it may be one of the most important sources of potash in Japan. The isolation of the potassium chloride is described; 80% of the potassium can be recovered as chloride of 80% purity.—F.W.A.

Catalysis. III. Some induced reactions. [Reduction of mercuric chloride, etc.] N. Dhar, Chem. Soc. Trans., 1917, 111, 690—706.

IN aqueous solution at 100° C. mercuric chloride is not reduced by oxalic acid but, under the influence of sunlight, formation of mercurous chloride occurs even at the ordinary temperature. A similar result is obtained in the dark on the addition of a drop of N/10 potassium permanganate to the aqueous mixture. This phenomenon appears to be of general occurrence; the reduction of mercuric chloride or bromide by oxalic acid, tartaric acid, citric acid, malonic acid, malic acid, glycollic acid, lactic acid, hydroxylamine hydrochloride, and hydrazine hydrochloride, of gold chloride by various reducing agents, and of silver nitrate, cupric chloride, and selenious acid by various organic acids, is promoted by the addition of such oxidising agents as potassium permanganate, persulphate, and nitrite, manganese dioxide, and hydrogen peroxide. Chromic acid and nitric acid induce the reduction of mercuric chloride by oxalic acid only in the additional presence of manganese sulphate, which exerts a marked catalytic effect on reactions of this type involving mercuric chloride, oxalic acid, and an oxidising agent; sulphuric acid on the other hand behaves as a negative catalyst. The possibility that the reducing effect in the above examples is due to the intermediate formation of hydrogen peroxide or of formic acid is discountenanced by the fact that these substances are not sufficiently active in this direction. Favour is given to the view that whether under the influence of light, of a catalyst, or of an inductor as described above, the effect is due to the intermediate transformation of the reacting molecules into an active condition.

—D. F. T.

Zinc sulphide; Phosphorescent—E. MacDougall, A. W. Stewart, and R. Wright, Chem. Soc. Trans., 1917, 111, 663—683.

PURE zinc sulphide prepared in various ways can

be obtained in a phosphorescent condition, but heat is necessary in order to produce this state; ordinary precipitated zinc sulphide shows no trace of phosphorescence. The addition of certain impurities has a marked effect in most cases, either inhibiting the phosphorescence, as in the case of iron, or altering the tint as in the case of manganese. The presence of a chloride, either of zinc or other element, increases the phosphorescence. The factor which has the greatest influence, however, is the temperature to which the zinc sulphide is heated, and this may be varied within limits. A sample heated for a very short time to a high temperature has been found to give effects similar to those observed in another sample heated for a longer time at a lower temperature, provided that the latter is not lower than about 750° C. Washing, rubbing, or disturbance of the final product in any way, tends to diminish its phosphorescent power. The amorphous sulphide does not phosphoresce, nor does the purely crystalline sulphide show such good phosphorescence phenomena as samples which contain semi-crystalline material. Specimens made from zinc salts free from chlorides, do not show such brilliant phosphorescence as those produced in the presence of chlorides. It is suggested that when the impure sulphide is heated, a surface film of zinc chloride is produced; and this film, on cooling, may contract and produce a strained condition of the material within the film. When manganese is present, however, it is difficult to avoid the conclusion that some chemical phenomenon must be concerned.—B.N.

Ozone; Determination of—and of oxides of nitrogen in the atmosphere. F. L. Usher and B. S. Rao, Chem. Soc. Trans., 1917, 111, 799—809.

THE ozone was estimated by making use of the reaction with sodium nitrite in dilute aqueous solution, this reaction taking place according to the equation: $O_3 + NaNO_2 = O_2 + NaNO$. Two samples of air were collected by displacement of purified water in 7-litre stoppered bottles. One sample was admitted through two tubes containing respectively chromic acid and powdered manganese dioxide, both compounds being specially purified, and the other sample was passed through a tube containing chromic acid only. The samples thus collected were shaken with 25 c.c. of N/40,000 sodium nitrite (made up with N/1000 sodium hydroxide in place of water), mixed with 100 c.c. of water. All the reagents used were specially prepared and purified. The nitrite content of the bottles was subsequently determined colorimetrically by the Griess-Hosvay method with α -naphthylamine and sulphanilic acid, the solutions being afterwards compared in a Duboseq colorimeter. The first sample of air contains only nitrogen peroxide, the ozone and hydrogen peroxide having been absorbed, and the increase of nitrite in the bottle is equivalent to the nitrogen peroxide absorbed. The second sample contains ozone and nitrogen peroxide, and the difference between the quantities of nitrite in the two bottles after shaking is equivalent to the ozone present. It is stated that the method will detect 1 part of nitrogen peroxide in 56 millions of air. In fourteen complete determinations made by the method on samples of air taken from the atmosphere in Bangalore, S. India, covering the period, July, 1916, to January, 1917, on no occasion was any ozone found. On two occasions, after thundery weather, with very little rain, nitrogen peroxide was present to the extent of 1 part in 5 millions and 1 in 4 millions respectively, but never exceeded 1 part in 20 millions on other occasions. There appears to be ground for the opinion that ozone and nitrogen peroxide never occur together in the atmosphere.—B. N.

PATENTS.

Nitric acid; Manufacture of concentrated—. K. Birkeland, Assignor to Norsk Hydro-Elektrisk Kvaelfstofaktieselskab, Christiania, Norway. U.S. Pat. 1,236,662, Aug. 14, 1917. Date of appl., Jan. 13, 1913.

A METAL capable of forming a nitrate is treated with dilute nitric acid and the solution of the nitrate evaporated. The salt is decomposed with steam to metal oxide and a gas containing oxides of nitrogen, the peroxide being converted into nitric oxide, which is converted into nitric acid by steam and oxygen.—J. H. P.

Radioactive mineral waters containing radium-precipitating acids; Preparation of—. H. C. Aggersborg, Frediksberg, Denmark. Eng. Pat. 101,295, Aug. 24, 1916. (Appl. No. 12,020 of 1916.) Under Int. Conv., Aug. 24, 1915.

THE radium salt and the other constituents of the mineral water—including those like sulphates and phosphates which precipitate radium—are dissolved separately in distilled water containing carbon dioxide under a pressure of 4 atmospheres. The two solutions are then mixed, the pressure being maintained, and the precipitation of radium thus prevented.—H. J. H.

Perborates; Manufacture of—. Deutsche Gold- und Silber-Scheideanstalt, Frankfurt, Germany. Eng. Pat. 106,460, Aug. 8, 1916. (Appl. No. 11,186 of 1916.) Under Int. Conv., May 17, 1916. Addition to Eng. Pat. 100,153 (this J., 1917, 83).

IN the process as described in the previous patent, the disintegration of electrodes of base metal, e.g., zinc, tin, or aluminium, can be diminished or avoided by the addition of small quantities of chromic acid or chromates to the electrolyte; 5 grms. of chromic acid to 10 litres of electrolyte has given good results in regard to colour of product and current efficiency. The parts of the electrodes not immersed in the electrolyte can be protected by a coating of varnish or vulcanised rubber. (Reference is directed in pursuance of Sect. 8, Sub-sect. 2, of the Patents and Designs Act, 1907, to Eng. Pat. 101,620; this J., 1917, 137.) —H. J. H.

Borax; Extraction of—*from mixtures containing boric acid or borax and sodium sulphate*. Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler, Frankfurt, Germany. Eng. Pat. 107,019, June 7, 1917. (Appl. No. 8160 of 1917.) Under Int. Conv., May 17, 1916.

A SOLUTION of sodium sulphate saturated or almost saturated with borax is heated to boiling, thus precipitating most of the sodium sulphate. This is separated and borax crystallised from the solution at 34° C. whilst the residual Glauber salt remains in solution. If boric acid is present soda is added.—J. H. P.

Sodium ferrocyanide; Method of making—. T. Boberg, and Techno-Chemical Laboratories, Ltd., London. Eng. Pat. 108,692, May 15, 1916. (Appl. No. 6935 of 1916.)

A MIXTURE of one part of coke and four parts of sodium carbonate is finely ground and heated to a bright red heat in presence of nitrogen, with the formation of cyanide and cyanamide of barium which are recovered by lixiviating with water. The barium is precipitated from the solution with sodium carbonate. The solution is treated at 0° C. with iron dust, and when no free cyanide remains the caustic soda is carbonated by blowing a carbon dioxide. The solution of sodium ferrocyanide and sodium carbonate is evaporated at 80° C. to crystallising point and slowly cooled, when sodium ferrocyanide crystallises out. At

35° C. the mother liquor is drawn off before soda crystals separate. The mother liquor is then cooled to a low temperature and the mixture of sodium carbonate and ferrocyanide deposited is used to precipitate barium from the melt.—J. H. P.

Base-exchanging bodies; Process of making—. G. Rudolf, London. Eng. Pat. 108,773, Oct. 17, 1916. (Appl. No. 14,763 of 1916.)

A 5% SOLUTION of sodium aluminate is added to a solution of sodium silicate. A gelatinous precipitate is formed which is collected in a filter-press or on a suction filter, and the press-cake dried, without washing, at 70°–100° C. The cake is exposed to the air for a day and plunged into water. This breaks it up into angular fragments, 1–2 mm. in diameter, and the water washes the cake. The material may be freed from water in a centrifugal machine or used directly.—J. H. P.

Prussic [hydrocyanic] acid; Process and apparatus for manufacturing—. Process of producing prussic acid. O. Liebknecht, Frankfurt, Germany, Assignor to Roessler and Hasslacher Chemical Co., New York. U.S. Pats. (A) 1,235,342 and (B) 1,235,343, July 31, 1917. Date of appl., Jan. 27, 1917.

(A) HYDROCYANIC acid is produced by the action of a high voltage arc upon a mixture of a hydrocarbon, hydrogen, and nitrogen. The mixture is passed through a chamber into which the electrodes project from small side chambers. Into the latter are led inert gases so as to sweep the space round the electrodes free from gases capable of depositing carbon and thus breaking down the insulation. (B) The process is worked under a pressure of about 1.6 atmospheres.—H. J. H.

Cyanogen compounds; Process of manufacturing—. H. Foersterling, H. Philipp, and R. N. Sargent, Perth Amboy, N.J., Assignors to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,235,887, Aug. 7, 1917. Date of appl., Oct. 29, 1913.

FINELY divided carbon, nitrogen, and the vapour of a metal are brought together in theoretical proportions at the boiling point of the metal, so that combination occurs. The reaction is exothermic, and once started, external heat is withdrawn, the temperature being maintained and regulated by feeding fresh supplies of the reagents at suitable rates and in suitable proportions.—H. J. H.

Ammonium fluorides; Process of producing—. H. F. Chappell, Assignor to Mineral Products Corporation, New York. U.S. Pat. 1,235,552, Aug. 7, 1917. Date of appl., July 17, 1913.

GASES and vapours containing silicon fluoride produced in the preparation of phosphoric acid and phosphate from phosphatic material containing fluorine, are brought into contact with a solution of ammonia. Ammonium fluoride and bifuluoride are produced and silica is precipitated. After separating the latter, the solution may be used for washing the gas again so as to obtain a more concentrated solution.—H. J. H.

Oxide of titanium; Process for obtaining—*from materials incorporating other substances*. L. E. Barton, Niagara Falls, N.Y., Assignor to Titanium Alloy Manufacturing Co., New York. U.S. Pat. 1,235,638, Aug. 7, 1917. Date of appl., Mar. 30, 1917.

MATERIAL containing titanium oxide is dissolved in a suitable acid and the solution electrolysed in the cathode chamber of a cell the electrodes of which are separated by a diaphragm. The anode chamber contains an acid solution. The cathode

solution is withdrawn and on heating deposits hydrated titanium oxide which is removed and calcined.—H. J. H.

Nitrogen: Fixation of—R. H. McKee, Ridgefield Park, N.Y., U.S. Pat. 1,236,853, Aug. 11, 1917. Date of appl. Oct. 26, 1916.

The reaction is effected in a container having exposed interior walls of an alloy of nickel, chromium, and iron. The composition of the alloy is approximately Ni 60, Cr 12, Fe 25%, with small quantities of manganese and carbon.

—J. H. P.

Potash: Recovery of—F. G. Breyer, Palmerton, Pa., U.S. Pat. 1,236,903, Aug. 11, 1917. Date of appl. Aug. 26, 1915.

CARBONACEOUS matter and refuse of low carbon content and high ash is burnt with limestone in a blast-furnace. The limestone forms a slag with the ash, and a sufficiently high temperature is used to volatilise the potash.—J. H. P.

Potash of felspar and similar materials: Process for rendering available the—W. Glaeser, Brooklyn, N.Y., Assignor to G. T. Bishop, Macedonia, Ohio, U.S. Pat. 1,237,197, Aug. 11, 1917. Date of appl. Sept. 16, 1911.

The material is burned at a low red heat, suddenly cooled, mixed with less than 20% of burned lime, and then fused at 1600° C. The product may be used in agriculture, or ground and treated with sulphuric acid to form potash alum.—A. B. S.

Chlorine gas: Process for producing—L. C. Jones and G. N. Terziev, Syracuse, N.Y., Assignors to The Solvay Process Co., Solvay, N.Y., U.S. Pat. 1,236,570, Aug. 11, 1917. Date of appl. Aug. 3, 1915.

AN alkali chloride is heated with ferric sulphate in the presence of oxygen. The ferric sulphate is formed by treating ferric oxide mixed with sodium chloride with sulphur trioxide at a temperature below that at which chlorine compounds are evolved.—J. H. P.

Magnesium chloride: Manufacture of anhydrous—E. A. Ashcroft, London, Eng. Pat. 108,755, Sept. 12, 1916. (Appl. No. 12,873 of 1916.)

SEE U.S. Pat. 1,231,711 of 1917; this J., 1917, 925. Carbon, or a sulphur compound, such as salena or zinc blende, may be added to the charge for the purpose of producing an exothermic reaction.

Magnesium chloride: Manufacture of anhydrous—alone or conjointly with other metal chlorides. E. A. Ashcroft, London, Eng. Pat. 108,920. (Appl. Nos. 13,259, Sept. 19, and 13,614, Sept. 26, 1916.)

SEE U.S. Pat. 1,232,169 of 1917; this J., 1917, 926. A sulphide or other substance may be added to promote the exothermic nature of the reaction.

Chalk: Manufacture of light precipitated—N. Statham, Boonton, N.J., U.S.A., Eng. Pat. 102,928, Aug. 11, 1916. (Appl. No. 11,171 of 1916.) Under Int. Conv., Dec. 23, 1915.

SEE U.S. Pat. 1,178,962 of 1916; this J., 1916, 631.

Titanic acid products: Manufacture of—H. Wade, London, From Titanium Alloy Manufacturing Co., New York, Eng. Pat. 108,693, June 15, 1916. (Appl. No. 8165 of 1916.)

SEE U.S. Pat. 1,189,229 of 1916; this J., 1916, 890.

Process of making window glass and hydrochloric acid. U.S. Pat. 1,231,457. See VIII.

VIII.—GLASS; CERAMICS.

Refractory brick: Testing of—C. E. Nesbitt and M. L. Bell, Amer. Soc. for Testing Materials, June 17, 1917. Met. and Chem. Eng., 1917, 17, 181-186.

Slag penetration. Tests involving the total immersion of a brick in a bath of molten slag did not give uniform results, besides requiring large and elaborate apparatus. The best results were obtained by studying the absorption of liquid slag in a pocket drilled into one face of the brick. The drill was pointed at an angle of 150°, and cut a hole 2½ in. in diameter, the depth at the side being ½ in. The hole was cleaned out, and the brick then heated to 1350° C. A known quantity of powdered slag was placed in the pocket, and after maintaining a temperature of 1350° C. for 2 hours, the brick was allowed to cool. When cold it was sawn in two, so as to bisect the original cavity at the centre, thus exposing an area of penetration of the slag. This area was measured by means of a planimeter. Increasing the duration of the test above 2 hours had no great effect, neither had the fineness of the slag, although it was usually ground to pass a 40-mesh sieve. Increasing the quantity of slag taken did not markedly affect the area of penetration if corrected for the differing area of contact.

Crushing test. The brick to be tested is ground so that opposite faces are parallel, measured, and heated in a furnace to 1350° C. The time taken to heat up should be at least 6 hours, and the temperature of 1350° C. should be maintained for 2 hours. The brick is then quickly placed in position in a testing machine of standard type, with asbestos board above and below the specimen. The crushing weight is determined.—H. J. H.

Refractory materials under load at high temperatures: Testing of—Amer. Soc. Testing Materials, June, 1917. Met. and Chem. Eng., 1917, 17, 186-187.

The following procedure is recommended in tentative tests submitted by the Committee on Refractories of the Amer. Soc. for Testing Materials. A full-sized brick on end is heated under load under specified conditions and the resulting deformation measured. A furnace is described. It is heated by two tangentially disposed burners—gas or oil—the flames from which are separated from the brick by a cylinder of alundum. The brick should be uniformly heated and its temperature measured by a thermo-couple, the junction of which is 1 in. from a face of the brick. Alternatively an optical pyrometer may be used. The brick rests on a highly refractory block, e.g., of carborundum, placed at the centre of the furnace, and carries another block of the same material which projects through the top of the furnace. The load is applied to this block by means of a cross beam, supported on guide pillars and carrying weights attached at each end so as to apply a pressure on the brick of 25 lb. per sq. in. The specimen is heated to the test temperature in 1½ hours and maintained there for 1½ hours. Silica material is tested at 1500° C., high-grade clay goods at 1350° C., medium at 1300° C., and low-grade at 1100° C. The cooling is slow and lasts 5 hours at least. The length of the brick is measured to 0.02 inch before and after test and the percentage decrease calculated.—H. J. H.

PATENTS.

Glass: Apparatus for the manufacture of—J. A. Chambers, Pittsburgh, Pa., U.S. Pat. 1,232,494, July 10, 1917. Date of appl. May 1, 1916.

A TANK of molten glass is provided with a ladle or

pot having a removable cover and a glass receiving port in the bottom. An air exhaust channel passes through the side wall of the ladle, near the top, and tongs are provided to grip the pot, the tongs having an exhaust channel which can be brought into communication with the air exhaust channel of the pot.—W. C. H.

Glass; Apparatus for the manufacture of —. J. A. Chambers, Pittsburgh, Pa. U.S. Pat. 1,232,495, July 10, 1917. Date of appl., May 9, 1916.

SUPPORTS are arranged in a tank furnace for supporting refractory vessels, and mechanism for grasping these vessels is provided, comprising a reciprocating arm with pivoted clamping jaws at one end, means for operating the jaws, and means for reciprocating the arm.—W. C. H.

Window glass and hydrochloric acid; Process of making —. W. Glaeser, Brooklyn, N.Y. Assignor to G. T. Bishop, Cleveland, Ohio. U.S. Pat. 1,234,457, July 24, 1917. Date of appl., May 1, 1916.

As a step in the manufacture of window glass, a mixture of sand, lime, sodium chloride, and carbon is heated to about 800° C. in the presence of steam in an open kiln.—W. C. H.

Refractory material; Manufacture of a porous mineral product for use in chemical and electrical operations, as a —, *and for other purposes.* M. Barrett, Leeds, Eng. Pat. 108,619, Dec. 2, 1916. (Appl. No. 17,304 of 1916.)

A POROUS mineral product composed essentially of crystalline silica or a vitrified silica-containing substance (e.g., porcelain or stoneware) combined chemically and mechanically by heat with a relatively small proportion of feldspar or feldspathic material. In the process of manufacture, tar, sodium or potassium silicate, and an organic adhesive may be incorporated with the other materials. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 4216 of 1873; 2470 of 1874; 22,784 of 1892; 684 of 1898; and 4355 of 1900; this J., 1894, 154; 1898, 764.)—W. C. H.

Brick kiln. G. C. Heilman, Philadelphia, Pa. U.S. Pat. 1,237,036, Aug. 14, 1917. Date of appl., Oct. 10, 1916.

In a gas-fired kiln of the Scotch type (see fig.), arched combustion chambers, built through the two side walls, are supplied with gas through

lower apertures and air through upper ones in such a manner that both gas and air are heated before they are mixed and burned in the combustion chamber.—A. B. S.

Clay; Treatment of —. W. Feldenheimer, London, Eng. Pat. 108,808, Aug. 11, 1916. (Appl. No. 1099 of 1917.) Addition to Eng. Pat. 106,890, July 10, 1916 (this J., 1917, 879).

SODIUM sesquicarbonate, ammonium carbonate, or potassium carbonate is used in place of the

sodium carbonate specified in the previous patent. It is stated that for suspending 500 parts by weight of china clay from Fraddon, Cornwall, in 10,000 parts by weight of water, the limits for sodium sesquicarbonate are 8.8 and 126.6; for ammonium carbonate 23.5—78.5, and for potassium carbonate 9.0—69 parts by weight. The two latter give results inferior to the sodium compound.—A. B. S.

Abrasive wheel. C. R. King, Assignor to Norton Co., Worcester, Mass. U.S. Pat. 1,235,325, July 31, 1917. Date of appl., May 28, 1914.

THE wheel consists of particles of abrasive material united by a silicate binder into a body with a porous structure, the voids of which are filled with a supplementary bond consisting of a synthetic resin which is applied to the wheel in a liquid form and is changed by the action of heat alone into a permanently solid substance, insoluble in water, and having a melting point higher than the temperatures attained in ordinary grinding operations.—W. C. H.

IX.—BUILDING MATERIALS.

Silica brick; Manufacture of —. C. E. Nesbitt and M. L. Bell, Amer. Soc. for Testing Materials, June, 1917. Met. and Chem. Eng., 1917, 17, 181—184.

IN America the raw material used for the manufacture of silica brick is ganister with 98% of silica and 1% each of iron and alumina, freed from contaminating foreign material. The selected ganister is ground to pass a 4-mesh sieve and ground with water and 2% of lime. For hand-made bricks, 10% of water gives a suitable mixture which is then moulded. Great care is necessary here if the bricks are to be free from defects. The bricks are then dried slowly and carefully in tunnels or on warm floors until bone dry, otherwise cracks may appear on firing. The bricks are burnt in down-draught kilns taking 50,000 to 150,000 bricks. They are taken up to cone 16 at which the temperature is maintained for 1 to 3 days. Ten to fifteen days are taken for the heating up and five days for cooling down. Experiments are recorded on the influence of pressure and fineness of grinding on the product. The pressure in making the bricks was varied from 187 lb. to 2500 lb. per sq. in. Tests on slag penetration, spalling loss, strength against impact, and linear expansion showed that little is gained by raising the pressure, although the product is denser. Tests were made on bricks made of material ground to pass 12-mesh, 8-mesh, and 4-mesh sieves. Fine ground material gave the stronger bricks but the coarser material was more resistant to spalling. The 4-mesh material pressed at 1500 lb. per sq. in. gave bricks which showed the same spalling loss as hand-made bricks, i.e., 30%. Besides being better shaped and finished. Power pressing is advocated instead of hand making.—H. J. H.

Portland cement concrete road construction; Influence of grading on the value of fine aggregate used in —. F. H. Jackson, jun. J. Agr. Res., 1917, 10, 263—271.

RESISTANCE of concrete roads to wear, i.e. to abrasion and impact, mainly depends on hardness and toughness of the material, and the author has studied the effect on these produced by grading the aggregate. For the tests, standard mortar briquettes and cylinders, 2 by 2 inches, were made from a mixture of 1 part of cement and 2½ parts of specially graded sand. Potomac River concrete sand was first divided into 3 sizes.

namely, coarse, composed of equal parts of material which passed a $\frac{1}{4}$ -inch screen, but was retained by a 10-mesh sieve, and of material which passed a 10-mesh but was retained by a 20-mesh sieve; medium, composed of equal parts of 20- to 30-mesh, 30- to 40-mesh, and 40- to 50-mesh material, and fine, composed of all that passed the 50-mesh. These grades were re-combined into 60 different combinations. Specimens for the hardness tests were prepared by drilling 1-inch cores through the centre of the 2-inch cylinders. The ends of the specimens were held against a revolving steel disc on to which quartz sand was fed as an abrasive. The loss of weight after 1000 revolutions was taken as an index of the hardness. When more than 10% of the coarse sand was present, the loss was very slightly more than that which a specimen of solid quartz would suffer. With the medium and fine sand, but no coarse, the loss increased about 40 times. When the ratio of cement to sand was as 1 : $1\frac{1}{2}$, the loss of specimens containing coarse sand was practically the same, but was reduced to about $\frac{1}{4}$ in the case of fine sand. When unscreened sand was used, the hardness of the mortar specimens was greater than that of neat cement, and was practically the same for all ratios of cement to sand up to 1 to 3. Toughness tests were made on 2 x 2 inch cylinders with the Page impact machine, a $\frac{1}{2}$ kilogram hammer being allowed to fall on the test-piece through 1 cm. for the first blow, 2 cm. for the second, and so on till the piece was fractured, when the height of fall in cm. was taken as the index of the relative toughness. Roughly, the toughness increases with the percentage of coarse sand and when any medium and fine sand present are in about equal amounts. Toughness increases as the ratio of cement to sand is increased up to the ratio of 1 : 1, but neat cement is no tougher. Tensile and compressive strengths were determined on standard briquettes and 2 x 2 inch cylinders. In tension and compression the maximum strength was obtained with an aggregate containing 70% of the coarse sand, 10% medium, and 20% fine; and the strength generally decreases with increase in fine material. For road construction it seems probable that greater resistance to wear would be obtained by increasing the coarse sand (the $\frac{1}{4}$ -inch to 20-mesh material) over what is usually considered good practice.

—W. C. H.

Testing of refractory brick. Nesbitt and Bell. See VIII.

Testing of refractory materials under load at high temperatures. See VIII.

PATENTS.

Road making. J. S. Robeson. Au Sable Forks, N.Y., Assignor to Robeson Process Co., Camden, N.J. U.S. Pat. 1,236,875, Aug. 14, 1917. Date of appl., Feb. 27, 1911.

The road is faced with a mixture of calcareous material, a clay-yielding silicate rock, and a preparation of sulphite waste-liquor containing a sesquioxide, such as alumina, and oil is subsequently applied to make the surface waterproof.—A. B. S.

Paving material. E. J. Lovegrove and N. G. Crompton, London. U.S. Pat. 1,237,920, Aug. 21, 1917. Date of appl., Mar. 2, 1915.

Bituminous grouting. E. J. Lovegrove and N. G. Crompton, London. U.S. Pat. 1,237,921, Aug. 21, 1917. Date of appl., Mar. 2, 1915.

SEE Eng. Pat. 12,973 of 1914; this J., 1915, 231.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Grey cast iron; Note on the heat treatment of —. Part I. J. E. Hurst. Iron and Steel Inst., Sept., 1917. [Advance proof.] 8 pages.

In connection with the rapid deterioration of the cast iron cylinder components of internal combustion engines, it is pointed out that in the Diesel engine the flame is driven directly against the centre of the piston head, the inner surface of which thus attains a temperature of at least 900–950° C. The characteristic "star cracks" produced in such piston heads after short periods of use are frequently traceable to mechanical defects; but, on the other hand, the strength of grey cast iron is known to decrease rapidly with increasing temperature. The analytical results of samples taken from various parts of cracked Diesel engine pistons showed the greater part of the combined carbon to have been converted into the graphitic form in every case, but no oxidation of carbon or silicon was indicated. Similar results as regards carbon were obtained when a series of grey cast iron bars containing 0.016–0.85% P, were heated to 750° and 900° C. for 2–4 hours and quenched in water, the temperature and varying phosphorus content being apparently without influence. When further samples of similar grey cast iron, containing 1.19% P, were heated for 5–15 mins. at 900°–950° C., it was found that a portion of the free carbon had been re-absorbed. Micrographic investigation showed that, in all the heat-treated samples, the worm-like graphite forms of the original grey cast iron had swollen and become somewhat thicker—a circumstance which is regarded as exerting a large influence on the weakening of the metal after subjection to heat. In the author's experience, the cracking of mechanically perfect Diesel engine piston tops is generally traceable to a high phosphorus content of the cast iron (normally about 1%) and can be practically eliminated by reducing the amount of this impurity to the lowest possible limit.—W. E. F. P.

[Steel.] *The acid open-hearth process.* F. Rogers. Iron and Steel Inst., Sept., 1917. * [Advance proof.] 12 pages.

In a critical survey of the principal features affecting the production of sound, clean ingots by the acid open-hearth process, the importance of ideal "dead melting" and of the proper use of lime and deoxidisers is emphasised. The conditions necessary for the full utilisation of the high degree of deoxidation obtained, and for minimising piping, are also considered; and top casting, through a refractory head into a mould with the wider end uppermost, is advocated.

—W. E. F. P.

Acid open-hearth steel; Investigation upon a cast of —. T. D. Morgans and F. Rogers. Iron and Steel Inst., Sept., 1917. [Advance proof.] 10 pages.

To determine the general quality and uniformity of a cast of acid open-hearth steel used for the manufacture of H.E. shell, some twenty ingots were investigated. Analyses were made of pit samples taken immediately before casting each ingot, and of the top, middle, and bottom billet from each ingot. The latter samples were also subjected to tensile and hardness (Brinell) tests and to micrographic examination. The analytical and mechanical results showed great uniformity throughout the series, while the variations of structure noted were only such as ordinarily occur in good steel of this class.—W. E. F. P.

Steels; Influence of heat treatment on the electrical and thermal resistivity and thermo-electromotive potential of some—. E. D. Campbell and W. C. Dowd. *Iron and Steel Inst.*, Sept., 1917. [Advance proof.] 12 pages.

THE specific resistance, thermal resistivity (ingot iron=1), and thermo-electromotive potential (against ingot iron) of a series of carbon, nickel, nickel-chromium, silicon, and manganese steels were determined after annealing at and quenching from appropriate temperatures. Curves are given showing the correlation of the thermal and electrical resistivities as influenced by the chemical constitution and heat treatment of the samples. In all cases, both resistivities were increased by quenching, the extent of the change corresponding closely with the carbon content of the steel. The results are discussed in the light of the hypothesis previously suggested (this J., 1916, 1018), in which the essential unity of mechanism of solid and aqueous solutions is assumed, and are regarded as conforming generally to the requirements of that conception.—W. E. F. P.

Steels; The heterogeneity of—. H. Le Chatelier and E. L. Dupuy. *Comptes rend.*, 1917, 165, 349–352.

THE composition of the metallographic reagent previously described (this J., 1915, 1050) has been modified to increase its sensitiveness, and even to bring out the heterogeneity of low phosphorus steels. The composition of the new reagent is:—Alcohol (95%) 100 c.c., water 10 c.c., cupric chloride crystals 1 grm., picric acid 0.5 grm., concentrated hydrochloric acid 1 c.c. to 2.5 c.c. The concentrations of copper chloride and picric acid may be varied somewhat without ill effect, but the concentration of alcohol must be adhered to. The proportion of hydrochloric acid must be determined by trial within the limits given to get the best results. A good plan is to prepare two solutions of limiting hydrochloric acid concentration, and to make up intermediate solutions by mixture. Time of contact in etching varies from 10 seconds to 1 minute, according to temperature. The structure is brought out normally by a brown non-metallic deposit on a bright metallic background. If a photograph is required, the effect is intensified with a stronger acid solution until the deposit has changed to metallic copper and the pattern is difficult to distinguish. The specimen is then placed as anode in a 10% solution of sodium bicarbonate and a current of density 0.1 amp. per sq. cm. passed through it. The thin portions of the patterns now pass into solution, exposing the bright metal background, while the thicker parts are oxidised to a black copper oxide deposit. This reagent discloses the heterogeneity of all steels, even those containing less than 0.015% of phosphorus. It is better for microscopic work than either sulphuric acid or iodine, although it has the disadvantage of necessitating a preliminary polish. Thermal treatment of the specimens may alter the intensity, but does not alter the form of the patterns. The cause of the heterogeneity thus displayed has not been ascertained with certainty. It is not due to the irregular distribution of carbon. It may be due to the cored structure of the original crystallites at the moment of casting.—H. J. H.

Copper refining; By-products in electrolytic—. L. Addicks. *Met. and Chem. Eng.*, 1917, 17, 169–176.

IN a previous paper (this J., 1917, 966) the various impurities associated with copper were discussed. In the present the methods of working them up to saleable products are described. Some of the by-products (the precious metals, lead, nickel,

and antimony) can be sold in any quantity produced; others, like bismuth, arsenic, cobalt, and selenium, have a very restricted market, while tellurium has practically no market; large quantities of tellurium and selenium could be produced if necessary. The working up of typical anode slimes is discussed. Up to 10% of copper may be present in the slimes, and this is reduced to 1% by hot leaching with sulphuric acid and nitre or by furnace oxidation and leaching combined. If the product is melted it separates into three layers, bullion, matte, and slag on top. The slag is skimmed and the matte blown to oxidise it, with the production of a second slag. This is skimmed and the bullion cleaned by air and nitre, with the production of a third slag. The bullion contains nearly all the gold and part of the silver, the rest being recovered from the slags. The bullion is parted either by solution with sulphuric acid or more generally by electrolysis. The possibilities of improving the above processes are surveyed. Mechanical concentration of precious metals by screening, dressing on tables, and by flotation methods, is discussed. Possible improvements in the oxidation and leaching out of the copper and in the smelting of the residue are suggested. Little improvement is to be looked for in the parting.—H. J. H.

Brass melting furnaces; Fuel economy possibilities in—. L. C. Harvey. *Inst. of Metals*, Sept., 1917. [Advance proof.] 16 pages.

THE over-all heating efficiencies obtained in present brass-melting practice are compared on the basis of the estimated output for 1916, viz., 2,000,000 tons of the 70:30 alloy melted and superheated to 10% above its melting point. The following ratios of total fuel consumed to that usefully employed are given, those for coke- and gas-fired furnaces being in terms of coal:—Coke-fired pit and tilting furnaces, 27:1 and 9:1, respectively; tilting furnaces using powdered coal, 6:1; single crucible pit or tilting furnaces using town gas, 13:1; multiple crucible pit furnaces or single crucible tilting furnaces using producer-gas, 12:1; oil-fired pit and tilting furnaces, 19:1 and 7:1, respectively. Notwithstanding the greater economy of the tilting furnace, pit furnaces employing smaller crucibles are still largely used on account of the better quality of metal produced. Suggestions are made for increasing the efficiency of coke- and oil-fired pit furnaces by improving the present designs; and drawings are given of a multiple crucible furnace for oil, gas, or powdered coal, which has proved satisfactory in use, and of a special form of grate pan for economising solid fuel in tilting furnaces.—W. E. F. P.

New system of gas firing. *Ionides.* See IIa.

PATENTS.

Metals [high-speed steel]; Means for the heat treatment [hardening] of—. P. Winn, Birmingham, and A. H. Wilkes, Four Oaks, Warwickshire. *Eng. Pat.* 108,826, Apr. 5, 1917. (Appl. No. 4912 of 1917.)

IN apparatus for hardening high-speed steel by quenching it in a blast of cold air, the cooling chamber is substantially cylindrical and is open at one end and closed at the other end through which the nozzle for the compressed air projects. The nozzle is provided with a series of openings directed radially outward or backward, and also a smaller central opening directed forward. The inner surface of the cooling chamber is grooved longitudinally, and a uniform distribution of the blast over the article to be cooled is obtained. The apparatus is combined with a gas-fired heating

furnace, the compressed air being obtained from a branch of the pipe supplying the air for combustion.—W. F. F.

Roasting or calcining furnaces: Mechanical

Akt.-Ges. für Zink-Industrie vorm. Grillo, and W. Scheffzik, Hamborn, Germany. Eng. Pat. 10,879, May 2, 1914.

SEE Ger. Pat. 287,078 of 1913; this J., 1916, 181. Regulated quantities of preheated air may be introduced into each muffle to accelerate the roasting process. An iron bar carried by arms projecting radially from a shaft mounted in the ends of the furnace structure, extends horizontally through each muffle, and is provided on its underside with two or more rows of teeth of triangular cross-section, not in alignment, and presenting oblique faces at each side. The shaft is oscillated, whereby the bar swings from side to side, and the teeth stir the ore and feed it forward.

[Ore roasting] furnace. F. J. Bowman, Assignor to The Grasselli Chemical Co., Cleveland, Ohio. U.S. Pat. 1,235,003, July 31, 1917. Date of appl., Nov. 10, 1916.

A NUMBER of superposed roasting hearths are connected together at alternate ends by sloping conduits, which make an acute angle with each of the hearths. The under wall of the conduit is formed as an arch which extends downwards into the hearth below and constitutes a wall against which the ore piles up and seals the hearth.

—W. H. C.

Furnace: Metallurgical —. U. Wedge, Ardmore, Pa. U.S. Pat. 1,237,129, Aug. 11, 1917. Date of appl., Dec. 2, 1915.

THE furnace is provided with a series of hearths arranged in the form of shelves at different levels, each of these, excepting the top one, projecting beyond the hearth above it. The escape of material over the edge of each projecting hearth is prevented by upstanding rims on the edges, and gaps, with inclined bottoms, are provided in the hearths for discharging the material on to the hearths below. Means are provided for moving the material over the hearths in a forward direction towards the gaps.—B. N.

Flux for hard soldering. H. R. Law, Glasgow. Eng. Pat. 108,778, Oct. 31, 1916. (Appl. No. 15,511 of 1916.)

TWO parts of hydrofluoric acid, one part of phosphoric acid, six parts of borax, and a small quantity of gum arabic, are intimately mixed together to form a flux.—B. N.

Metals [zinc or spelter]: Furnace for refining

G. Kermode, London, and A. R. Miller, Birmingham. Eng. Pat. 108,782, Nov. 1, 1916. (Appl. No. 15,800 of 1916.)

A FURNACE particularly adapted for refining zinc or spelter comprises a closed muffle having flues along the top and on both sides. The furnace is arranged below the muffle, at one side and at the front end, and baffle-plates are provided in the flues so that the gases pass up one side, transversely across the top, and down the other side to the next upward passage, and so on backward and forward till the further end of the muffle is reached. The gases then pass through a flat transverse passage below the muffle to an exhaust stack. The muffle floor slopes downward from front to rear, and metal containers are sunk in the floor near the rear end so that molten metal of an increasing degree of purity may drain into them in succession.—W. F. F.

[Zinc: Method and] furnace [for purifying —]. R. Ziesing, Assignor to The Grasselli Chemical Co., Cleveland, Ohio. U.S. Pat. 1,237,141, Aug. 14, 1917. Date of appl., May 4, 1916.

IN purifying zinc from heavier metals, the zinc is heated to a temperature just above the melting point, and the heavier metals which settle are drawn off separately from the relatively pure zinc above. The zinc is transferred to a distilling chamber connected with the melting chamber, the distilled zinc is collected, and the heavier portion allowed to drain back into the melting chamber.—W. F. F.

Carbon residues from the distillation of petroleum: Composition of matter for adapting — for use in smelting furnaces. E. D. Kendall, Elizabeth, N.J., Assignor to L. T. Haggin, Closter, N.J., and M. V. Haggin, A. McCulloh, and H. E. Moller, New York. U.S. Pat. 1,236,447, Aug. 14, 1917. Date of appl., July 26, 1912.

CARBON residues from petroleum distillation are crushed, and mixed with a cement composed of silica, lime, and alumina, and with freshly burnt lime, and the mixture is briquetted.—W. F. F.

Precious metals and other metals: Process of extracting — from ore. J. M. Tippet, Colorado Springs, Colo. U.S. Pat. 1,236,501, Aug. 14, 1917. Date of appl., Dec. 23, 1916.

THE ore is mixed with an equal or greater quantity of cyanide solution, and alkali added in quantity sufficient to neutralise the acidity of the ore. Oil in quantity less than 1% of the ore is then added, gas bubbles are produced in the mixture, and the values recovered by flotation.—W. F. F.

Ores: Concentration of — by flotation. G. D. Van Arsdale, New York. U.S. Pat. 1,236,504, Aug. 14, 1917. Date of appl., Feb. 7, 1916.

HYDROGEN sulphide is supplied to the ore-bearing pulp, during agitation, in excess of the amount required to combine with the non-sulphide mineral present, and the treated pulp is allowed to stand until the excess of gas has been absorbed. The mineral and gangue are then separated by flotation.—B. N.

Ore concentration. R. B. Martin, Assignor to Minerals Separation North American Corporation, New York. U.S. Pats. (A) 1,236,856 and (B) 1,236,857, Aug. 11, 1917. Date of appl., Jan. 28, 1916.

(A) ORE pulp containing oxidised copper is mixed with a soluble sulphide and agitated and aerated under such conditions that the oxidised particles are not coated with a visible layer of sulphide. A froth of concentrates is thus obtained and separated. (B) Ore pulp containing copper is agitated and aerated with a frothing agent prepared by heating an oil with sulphur to about 250° C. and allowing the distillate to return to the mixture during treatment. A froth of concentrates is obtained.—W. F. F.

Flue-dust: Apparatus for extracting values from —. T. F. McGrath, Anaconda, Mont. U.S. Pat. 1,236,581, Aug. 14, 1917. Date of appl., Feb. 2, 1915. Renewed May 16, 1917.

THE products to be treated are forced into a closed tank through delivery pipes spaced along the bottom. Liquid is passed through the tank from one end to the other in a tortuous path formed by vertical baffle-plates, and horizontal perforated screens are provided between adjacent baffle-plates.—W. F. F.

Filter-press [for hydrometallurgical processes] and method of preventing the oxidation of the filtrate in the containers thereof. L. D. Mills, San Francisco, Cal., Assignor to Merrill Metallurgical Co. U.S. Pat. 1,236,737, Aug. 14, 1917. Date of appl., Dec. 24, 1912.

THE oxidation of the precipitate and precipitant, in the containers of open top-discharge filter-presses in which hydrometallurgical precipitation and filtration is effected, is prevented by discharging the filtrate from each filter-plate at a point above the uppermost limit of the mixture within the press, whereby the admission of air into the containers is avoided.—B. N.

Welding or fusing of nickel and alloys containing a high percentage of nickel; Method of auto-genous —. R. Samesreuther, and Autogenwerk Sirius, Ges.m.b.H., Düsseldorf-Eller, Germany. Eng. Pat. 24,646, Dec. 24, 1914. Under Int. Conv., Dec. 29, 1913.

SEE U.S. Pat. 1,221,418 of 1917; this J., 1917, 655.

Roasting or calcining furnaces; Mechanical charging apparatus for —. *Hydraulic mechanism for actuating the stirring and feeding apparatus of mechanical roasting and calcining furnaces.* Akt.-Ges. für Zink-Industrie vorm. W. Grillo, and W. Scheffzik, Hamborn, Germany. Eng. Pats. 109,036 and 109,037, May 2, 1914. (Appl. Nos. 9127 and 9128 of 1917.)

SEE Fr. Pat. 473,310 of 1911; this J., 1915, 557.

[Mercury] boiler. U.S. Pat. 1,236,155. See I.

Drawn filaments for electric incandescence lamps. Eng. Pat. 198,847. See III.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Depolariser; Higher oxide of manganese —. A. A. Wells, Montclair, N.J., Assignor to National Carbon Co., Long Island City, N.Y. U.S. Pat. 1,232,873, July 10, 1917. Date of appl., Oct. 22, 1915.

A DEPOLARISER, for miniature dry batteries of the Leclanché type, comprises an oxide of manganese having more oxygen than corresponds to MnO_2 , but less than corresponds to Mn_2O_3 , associated with a form of artificial manganese dioxide.—B. N.

Depolarising agent; Manganous manganate and permanganate —. C. Ellis, Montclair, N.J., Assignor to National Carbon Co., Long Island City, N.Y. U.S. Pat. 1,232,901, July 10, 1917. Date of appl., Oct. 25, 1915.

MANGANOUS manganate, in a flaky form, is used as a depolarising agent in dry batteries.—B. N.

Electrolytic gas generator. C. F. Euler, Topeka, Kans. U.S. Pat. 1,234,319, July 21, 1917. Date of appl., May 5, 1916.

AN electrolytic tank is partly filled with liquid, and a number of negative electrodes are spaced apart horizontally across the tank, the ends of the electrodes being secured to the adjacent walls, so as to keep the electrodes out of engagement with the bottom of the tank. The positive electrodes are similarly spaced apart and secured to the walls above the negative ones, but are disposed below the surface of the liquid.—B. N.

Electrolytic cell. F. G. Wheeler, Assignor to Bleach Process Co., Appleton, Wis. U.S. Pat. 1,236,025, Aug. 7, 1917. Date of appl., Oct. 30, 1915.

AN electrolytic cell is composed of a container, with a cathode-diaphragm within it supported by the base of the vessel and forming one wall of an anode vessel. A hollow column is located in the interior of the cell, and is supported wholly on the bottom of the anode vessel, the column serving as support for a removable anode cover. The latter is thus supported independently of and at an elevation lower than the upper marginal edge of the cathode-diaphragm, thus permitting the anodes to be supported by the cover and entirely immersed in the electrolyte throughout their length below the cover. The hollow column forms an internal feed cup for the anode compartment.—B. N.

Electrode-packing for melting furnaces. M. Sperling, Assignor to F. Krupp A.-G., Essen, Germany. U.S. Pat. 1,231,946, July 31, 1917. Date of appl., Nov. 13, 1911.

AN annular member, cooled by a fluid, and rigidly secured to the roof of the furnace, is provided with a flange, projecting inwards, on which is seated a liner of insulating material. The flange and liner are provided with central openings of greater diameter than the electrode, so that the latter has considerable play, and a tight-fitting packing ring is placed around the electrode. The ring is suspended from the top of the liner and is situated loosely on the top of the annular member, so as to permit movement of the electrode in the openings in a direction transversely to the axis. The packing ring is provided with an outer metallic casing and a core of insulating material.—B. N.

Furnace; Electrical induction —. *Multiphase induction furnace.* J. R. Wyatt, Assignor to The Ajax Metal Co., Inc., Philadelphia, Pa. U.S. Pats. (A) 1,235,629 and (B) 1,235,630, Aug. 7, 1917. Date of appl., July 19, 1916.

(A) The walls of the furnace body are adapted to contain a pool, and also to form a closed channel connected at both ends with the pool well below the normal surface. The channel is provided with an acute-angled bend at a distance from the furnace proper, and is obtuse-angled at its points of connection with the pool, so that the channel is converging in direction where it enters the pool. The walls of the furnace are made of a first-class electric conductor, a transformer-inducing current being passed through the channel walls, with the contents of the channel as secondary. An outward flow of material into the pool is produced from each channel toward the other, by means of motor drive. (B) The pool of the furnace may be connected with several parallel acute-angled channels meeting the pool in a generally upward direction, and a multi-phase transformer is employed for applying a different phase of the current to the induction of current as secondary in each of the channels. Thus, three channels may be employed, with the contiguous connections of different channels located near the apices of a nearly equilateral triangle, and with a three-phase transformer embracing one leg of each channel.—B. N.

Electrically insulating liquid; Unflammable —. G. Lépine, Neu-hâtel, Switzerland. U.S. Pat. 1,235,339, July 31, 1917. Date of appl., Apr. 13, 1914.

A MIXTURE of 93% of pentachloroethane, 5% of dichloroethane, and 2% of hexachloroethane.—B. N.

Electric furnaces. British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 108,902, Aug. 28, 1916. (Appl. No. 12,117 of 1916.)

SEE U.S. Pat. 1,206,603 of 1916; this J., 1917, 90.

XII.—FATS; OILS; WAXES.

Decolorising-carbon. See IIb.

PATENTS.

Oils; Process of refining saponifiable —. C. Baskerville, New York. Eng. Pat. 101,097, Aug. 2, 1916. (Appl. No. 10,908 of 1916.) Under Int. Conv., Aug. 2, 1915. (See U.S. Pat. 1,105,741 of 1914; this J., 1914, 930.)

THE oil is agitated with alkali and with cellulose material (other than mechanical paper pulp), which, after separation of the bulk of the oil, is pressed to remove as much as possible of the remaining oil. The efficiency of the process is increased by impregnating the absorbent material with alkali sufficient or in excess of that required to neutralise the free fatty acids in the oil. After being pressed the residue in the press may be digested with an alkali to form a soap product containing the absorbent material as a filler. Cotton fibres, or "linters," preferably cut into short lengths, are a suitable absorbent material, undue absorption of oil being prevented by moistening the material with water or an aqueous solution of alkali. To prevent the soaps formed in the process producing emulsions, an addition of an anhydrous salt, such as sodium carbonate (soda ash), capable of taking up water of crystallisation, may be made to the oil during the treatment, as described in U.S. Pat. 1,130,698 of 1915 (this J., 1915, 431).—C. A. M.

Compressing machine or apparatus, also adapted for expressing oil or other liquid from seeds and other materials. B. C. Barton, North Ferriby. Eng. Pat. 108,329, May 3, 1916. (Appl. No. 6317 of 1916.)

THE apparatus comprises a fixed drum or chamber constructed of top and bottom plates, having between them piles of plates arranged radially, so as to provide radial passages from the interior to the exterior of the drum. The seed, or other material, is fed into a box or casing, which rotates within the fixed drum, and is forced downwards by means of a worm screw on a vertical shaft, and then outwards into the radial passages by the pressure of a loosely mounted rotatable wheel, the teeth of which engage with teeth upon the inner ends of the plates. Here the oil or other liquid is expressed, and the residue is extruded through the periphery of the drum in strips or lengths, which fall upon a rotating ring or table, and are cut into pieces of the required size by means of attached knives.—C. A. M.

Oils or liquids from seeds, nuts, and other solids; Machines for expressing —. G. R. Schueller, Kingston-upon-Hull. Eng. Pat. 108,515, Aug. 19, 1916. (Appl. No. 11,781 of 1916.)

THE material is expressed in an annular chamber formed by two concentric tubes built up of rings, or the like, in which are passages or grooves for the escape of the oil. The outer wall is longer or higher than the inner wall, so as to enclose the compressing worm, or a portion thereof, and this worm has two or more sets of semi-helical threads or ribs, all or each two sets of which may be separated by a plain annular space. The rings, or the like, forming the inner wall of the expression chamber may be mounted so as to rotate with the compressing worm, and as the expressed material is expelled from the chamber it may be divided into portions by means of knives at the outlet. (See also Eng. Pat. 27,991 of 1913; this J., 1915, 92).—C. A. M.

Oil; Method of recovering — from "foots." O. C. Hagemann, Yonkers, Assignor to C. A. Dieterich, Mount Vernon, N.Y. U.S. Pat. 1,232,913, July 10, 1917. Date of appl., Nov. 4, 1913.

THE material, e.g., "foots" from cotton seed oil, is suspended in several times its volume of a liquid, such as a solution of sodium sulphate, the density of which can be increased, and the mixture is heated to about 95° C. so as to cause the oil in the "foots" to separate readily and rise to the surface.—C. A. M.

Soap powder; Process and apparatus for the manufacture of —. A. Haeblerle, Göppingen, Germany. Eng. Pat. 101,863, Aug. 26, 1916. (Appl. No. 12,113 of 1916.) Under Int. Conv., Mar. 16, 1916.

THE materials (e.g., sodium carbonate, water, and soap), are stirred together, while hot, in a mixing apparatus, and cold air then blown into the mass which is still agitated until a fine powder is obtained. Apparatus claimed for this process comprises a kneading trough containing a perforated pipe for the introduction of hot air, and provided with a cover to prevent the powder being blown out of the trough.—C. A. M.

Lubricant testing machine. Eng. Pat. 101,975. See XXIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Phosphorescent zinc sulphide. MacDougall and others. See VII.

PATENTS.

Red lead and orange lead; Manufacture of —. C. A. Rowe, Liverpool. Eng. Pat. 108,735, Aug. 23, 1916. (Appl. No. 11,963 of 1916.)

THE rabbles, in a mechanically operated oven for the manufacture of red lead or orange lead, are disposed around the centre of the hearth, and consist of straight, curved, or tapered plates mounted on a frame or carrier, which is preferably adjustable for varying the position and height of the rabbles with respect to the hearth. One rabble, or series of rabbles moves the material under treatment from the centre to the circumference of the hearth, and another rabble, or series of rabbles moves the material in the opposite direction.—B. N.
